Among civilised peoples to-day there was more danger from over-feeding than from under-feeding; hence the withdrawal for a time of some or all the normal food was recognised as being good for many diseases. Starvation had been defined as the want of that material which the organism needed, either in whole or part. It had been well said that a man could do without oxygen for a few minutes, without water for a few days, without food for a few weeks. It was the last which was now being considered, and when food was withdrawn for therapeutic purposes, water was given freely. Starvation might be complete, except for water, or might be partial; that is, a mixed diet might be given containing all essential foodstuffs, being simply, in total, of low caloric value. In complete starvation the predominant symptom was hunger, which was not synonymous with appetite, for a person could have an appetite without suffering hunger, and things liked could be eaten even when hunger had been satisfied. Indeed, most people had never really experienced hunger. Hunger consisted of definite pain at the lower part of the sternum, a pain which was insistent but intermittent. It did not come on until some time after the stomach had been emptied. Weber, 70 years ago, ascribed this pain to contractions of the stomach. Dr. Spriggs thought that the most valuab report on the symptoms of starvation was that Benedict, who fasted 31 days. When food w withheld, the body was not at once starved; it simp lived on its store instead of on food ingested. Wh food was not taken, almost the only part of the bo which was thereby saved work was the alimenta canal. Body-weight was lost rapidly at first, th settled down to a weight loss of about 1 lb. per die Those who had plentiful fat naturally had a larg store to draw upon. Starvation limited both t internal and external movements of the body, a on the seventh day of the fast the man had got h expenditure down to 1700 calories in place of t 2500 normal. When fasting, the body showed great power of internal economy, and the end can when mobilisation failed, death occurring when a adequate amount of nourishment was not suppli to some important organ of the body, despite t fact that there might still be some of the store le One man who fasted 31 days had at the end this time a systolic pressure of 110, compared wi one of 132 when he commenced his fast. In anoth case a blood pressure of 120 dropped to 110 or 10 In the case of a man in Germany, hunger-strikin during the war, the systolic pressure fell to 55. T temperature did not fall, or only very little, duri a fast, but prolonged and curious mental stat might arise in the process. Commonly, fasti people felt that they had more mental and physic energy than usual, but this sensation was not bor out by actual tests. The power to fast and st remain efficient varied a good deal with individua Tanner had fasted 40 days, but a man seeking emulate him had to give up on the fourteenth da Apart from fat, the first loss of weight during a fa fell on the glands—liver, spleen, and pancreas. Ne the muscles suffered. Heart and brain showed good deal of conservation. At the end of a long fa the heart was found to have lost 20 per cent. of i weight, and the brain 15 per cent.

When food was stopped the first call was on t glycogen in the liver, whose store was soon almo used up, but hardly ever had it been found that t last part of the glycogen had gone from the bod When this had been depleted, the body called up its much more mobile stores of nitrogen, using the deposited protein in four or five days. T excretion of nitrogen was then 11 or 12 g. a da If other than protein food was being given—star or fat—the excretion of nitrogen could be kept lo During fasting the main source of energy was t fat; only when the available fat had been used was the use of protein increased. Owing to the lar oxidation of fat, the person was apt to have acidosi this could be detected early in the fasting by estimati the alveolar CO_2; it was also shown by a considerab excretion of acetone as a later phenonemon; it w regarded as the cause of the headaches complained by fasting people. The fasting treatment of epilep had now been supplanted by giving a diet containi no carbohydrate, thus giving food but causing much acidosis as possible. Some held that fasti "cleared the blood"; but the nitrogen content the blood was found to alter very little, any alterati being in the direction of concentration. There w more than the normal uric acid in the blood of fasting person, and amino acids were present small quantity; they were not increased, though t globulin content rose to some extent. The amou of calcium and fat in the blood was increased duri a fast. People with achylia experienced the sam sensation of hunger as did other people.

Fasting had no known specific effect on the healt body except to call into being its whole resistance the risk of a "protein death." The idea that t bowel could be purified by fasting was negatived actual observation on the intestinal flora. T "experiment" of the late war confirmed the scienti work of the previous generation as to what were t needs of the people. During a great part of the w the German people averaged about 1300 calori

ly, and in a general way considerable body-weight s lost. There was, likewise, a lessened efficiency d a greater tendency to disease. It was noticed ring this period that few diabetics and cases of esity were seen by medical men. For a long time er the war nervous sequelæ persisted, pernicious æmia was common, myœdema cases became worse, did influenza patients, and diarrhœa was very quent. In the same way, convalescence from ease was slower, due to the lack of proper food. st digestive diseases increased markedly during s period, not only because of the food intake being minished, but also due to a large part being vege- ble food. For a considerable proportion of the ple a vegetable diet was not suitable.

Starvation in Disease.

Dr. Spriggs said that starvation was used for local ease of the alimentary canal; for acute conditions h as acute appendicitis and peritonitis it was valuable temporary measure. For general states should not be prolonged; short complete fasts re good in many complaints—i.e., giving no food, t allowing plenty of fluid, for two or three days. was stated in Germany that all endocrine activities re diminished by fasting, as also was the activity the sexual glands. Experimental animals fed ely had a more rapid growth of any tumours than en food was restricted, and it was probably alleled in the case of man. In nephritis work s spared the kidney by cutting off some of the d intake; also, because the calcium in the blood s increased by fasting, the latter was good for kets and for the vomiting of pregnancy. When pregnant woman fasted for a short time it did t adversely affect the child.

Fat could be got rid of either by increasing the enditure of energy or by diminishing the intake food. But it was found that as increased exercise ant increased appetite, no measure was effective ich did not definitely cut down the food. He d not found that such measures as massage, baths, ., really brought down the weight. He gave to patients mixed diets of carefully measured quan- ies. The most successful cases were those which eived the commencement of the treatment in an titution, and were then given tables and quantities work by. He had now, for working purposes, a ge variety of tables, designed to suit all kinds of cases. believed in allowing four meals a day. Towards tenth day of restriction it was usual for patients feel depressed and miserable; it was then well to e a generous chop, or something of the kind.

The speaker advised medical men to have nothing say to the woman who, though not obese, wished weigh a stone or so less. A man weighing, at years of age, 25 st. 11 lb. (height 5 ft. 8 in.) com- ined of breathlessness and headaches, as well as eeded movements. As he had a quick pulse he s not allowed to indulge in exercise for some time. eatment in his case was carried out for eight and a f months, at the end of which time his weight nt down to 11 st. 11 lb. That was nine years a. Reporting himself a year ago, he said he had n at business ever since; he then weighed 16 st. ese people showed a marked tendency to develop betes. An ordinary reduction of diet, without ting off carbohydrates, suited many cases of mild betes very well. Insulin, happily, had now come efully to the rescue.

Fasting was a cult, and the method was liable to se, inside as well as outside the profession. Special ures," like the "potato cure," or the "orange e," nearly all had the weakness that they did supply the fundamental amount of nitrogen the needs of the body. He concluded by relating ase of death from one of these cures at Göttingen, harge of manslaughter arising from it, and a fine 300 gold marks.

Discussion.

Dr. PARKES WEBER characterised fasting as a untary return to the involuntary habits which dominated the lives of our primitive ancestors for thousands of years. At that period none survived who were unable to accommodate themselves to the hard conditions of primitive life, a life of which intermittent fasting formed a part. He divided present-day humanity—for this purpose—into (*a*) those who seldom ate more than was good for them; (*b*) those for whom the maintenance of full bodily health meant intermittent periods of food limitation. In some people such restriction of diet was followed by a lessened liability to cold and sore-throat. It might also be good for hyperthyroidism.

Dr. A. FEILING showed and demonstrated the temperature chart of a case in which starvation resulted in a dramatic termination of fever. The patient was a young man, aged 21, who for a week before admission to hospital had been showing a temperature of 103° F. in the evenings. It seemed to be typhoid or paratyphoid. The abdomen was distended and somewhat tender, but he never had a rash, and the spleen was not palpable. He was starved, except in regard to water, for three days. Then followed a diet consisting entirely of sour milk. The temperature never rose again and the patient was discharged cured.

Dr. E. GRAHAM LITTLE, M.P., said he could probably be described as somewhat of a crank in the use of starvation in the treatment of skin diseases. These diseases admitted of no pretence, they were on the surface, and if the patient was not cured the fact was obvious. He had had some amazing results from carrying out a certain degree of starvation. His interest in this means was aroused ten years ago during a visit to New York, when one of the best known dermatologists there, himself a sufferer from a skin disease, controlled it by a diet of rice, bread and butter, and water. He was able to live comfortably on the diet for a week or so without losing weight appreciably. But a more effective method, which Dr. Graham Little recently became cognisant of, was that going under the name of Welper, of Paris. He took over to Dr. Welper a medical friend who was obviously dying of diabetes. On instructions the patient began to starve, and did so regularly on two days a week. That was seven years ago; the sugar had been kept in abeyance, and the subject of the condition was still carrying on a lucrative practice.

The method which the speaker had prescribed now for eight years was a combination of fasting and purging, the latter being, in his view, as important as the fasting for the purpose in view—namely, the detoxication of the system. He enjoined fasting for 36 hours, no food being taken except orange-juice and water; also a large dose of aperient—Dr. Welper favoured Glauber salts. The modern conception of skin diseases consisted largely of the idea that they were cutaneous reactions to the absorption of various toxic products, some autogenous, some from outside.

One remarkable case was that of a patient with acute lichen planus, the irritation from which, as was well known, sometimes drove the sufferer almost mad. He prescribed for this patient two days' fasting, giving a purge on the first day. He did not see the patient again, nor hear from the doctor, but he encountered the latter recently and learned that within a week of the short course the eruption had vanished.

Dr. H. A. DES VŒUX said he had used starvation in two types of cases. One was that of the overfed child of rich parents, who was given frequent feedings, and who was recognised by the distended abdomen. They usually looked wizened and unhappy. The effect on them of the starvation treatment was very striking. The other type in which he used it was the patient who had an acute illness, like pneumonia. For 20 years he had used for these cases the water treatment. It was a great mistake in these cases to have the nurse giving food of some kind to the patient at frequent intervals. Such patients were too ill to digest food, and they should not be troubled with it. They never died of starvation, because

they had a good reserve of food on which they were able to draw.

Dr. A. CAWADIAS said people undergoing starvation felt very well during the first few days of it. But there then followed a period of apathy, with no zest for food, and a progressive loss of weight set in, with a lowering of the blood pressure and a slowing of the pulse. The patient was then in a condition of indefinite equilibrium, and any infection would be followed by a catastrophe. After about ten days there ensued the state in which starving people had died—convulsions, coma, and other collapse symptoms. There were two distinct phases in starvation. In the first the digestive organs were at rest, and any imperfectly metabolised products which happened to be present were metabolised completely, and there was also mild protein shock caused by some disintegration of protein. In the second there was a complete change, the thyroid being in a condition of atony, while the nervous system was disturbed. The urea nitrogen in the blood, also, was increased, and later occurred a disturbance of the mineral equilibrium, with a fall in the sulphur content. The lesson of this was that in carrying out this treatment the toxic phase must be avoided.

Dr. GEORGE GRAHAM said the occurrence of hunger pains in people who were undergoing starvation treatment could be taken as an indication that the carbohydrate in the diet had been brought too low. There was too little sugar in the blood. If, in the case related by Dr. Spriggs, in which the diet was reduced to 700 calories value, the carbohydrate had been increased to 80, there would have been no need to give either extra meat or bovril.

Reply.

Dr. SPRIGGS dealt briefly with the points raised. In pneumonia he gave fruit juice in preference to water, and added to it glucose. Single-food "cures" were very useful for odd days; six oranges in a day was to the patient a very grateful change from the prescribed dietary when the latter had begun to pall. He agreed with Dr. Cawadias as to the importance of avoiding the stage when there occurred a disintegration of protein. An increase of sulphur he took to be evidence of tissue breakdown. He agreed with Dr. Graham's remark.

EDINBURGH OBSTETRICAL SOCIETY.

AT a meeting of this Society on Jan. 9th, with Dr. HAIG FERGUSON, the President, in the chair, Dr. H. S. Davidson, Dr. Douglas Miller, and Dr. Elsie Crowe communicated a paper on

ECLAMPSIA.

Dr. DOUGLAS MILLER began by referring to the discussion on the prognosis and treatment of eclampsia at the Congress of Obstetrics and Gynæcology at Liverpool in 1922. At this congress, he said, the advantages of conservative over more radical methods of treatment were so convincingly emphasised by the relatively low mortality in the Dublin group of cases that the Dublin method of treatment, with minor modifications, had been employed as a routine in the Edinburgh Royal Maternity Hospital during the five-year period 1923–27 inclusive. Dr. Miller presented a survey of 159 cases of eclampsia treated by this method and comprising an analysis of such symptoms and signs as coma, the number of fits, the degree of œdema, the degree of albuminuria, blood pressure, pulse-rate, and temperature in their relationship to prognosis. He said that the findings largely confirmed what was already believed in regard to the prognostic significance of these phenomena. An important exception, however, was noted in regard to blood-pressure readings, for in the series of cases studied, the mortality-ratio had proved to be in inverse proportion to the height of the blood pressure. When the systolic blood pressure at the time of admission to hospital was under 150 mm. H a case mortality of 27 per cent. was recorde whereas, in a second group, with blood pressu ranging from 150–180 mm., the case mortality w 14 per cent., while in cases in which a blood pressu over 180 mm. was noted, the case mortality was per cent. No satisfactory explanation could offered for figures so much at variance with what w generally believed about the serious prognos significance of high blood pressure in eclampsia. was found that while the absence of œdema w associated with a mortality of 24 per cent., t presence of marked œdema carried with it a deat rate of over 30 per cent., a moderate degree of œde being much less serious than either extreme. Furth investigation showed that in each of the four fa cases in which œdema was absent, death result directly from intense toxæmia, whereas in 5 out of t 12 fatal cases in which œdema was extreme, p monary complications contributed largely to t fatal issue, death being due directly to pulmona œdema in four of them. It would appear, therefo that while the absence of œdema was a sign of gre danger, possibly because it implied concentration toxins in vital tissues, extreme œdema carried with a special risk of pulmonary involvement.

The fœtal and neonatal deaths numbered giving a mortality percentage of 39·1. The exc sion of 28 cases in which the child was deliver before the thirty-sixth week of pregnancy, and 14 cases in which the child was believed to be de at the time of the patient's admission to hospit gave a reduced fœtal and neonatal death-rate 18·5 per cent. There were 28 maternal deaths in t whole series, a mortality-rate of 17·6 per cent. T figure compared with a mortality of 25 per ce during the ten-year period 1912–21. The causes death, confirmed in 22 cases by autopsy, were follows: toxæmia 13 cases, pulmonary complicatio 7 cases, cerebral hæmorrhage 6 cases, septicæmia case, and acute heart failure 1 case. In conclusio Dr. Miller said that while in general the intensity toxæmia could be reliably gauged by the exte and severity of the signs and symptoms specia considered, it was necessary to bear in mind t notoriously uncertain course which any case eclampsia might follow, so that even when the ome were favourable, response to treatment might f suddenly and apparently without reason, so th hopefulness was replaced by grave anxiety. particular, it had been found in this series that t occurrence of cerebral hæmorrhage seemed to be little relationship to the severity of the disea In only one of the six cases in which death was d to this complication had the toxæmia been so sev as of itself to make the prognosis anxious, nor any of them had the systolic blood pressure exceed 180 mm. In a hæmorrhagic toxæmia of this natu the occurrence of hæmorrhage in the brain, or, the other hand, in some less vital tissue, such as t liver, appeared to be largely a matter of chance a an accident over which the attendant had little no control.

Dr. ELSIE CROWE then gave a short résumé of t chemical findings in 86 cases of eclampsia. As result of these investigations she was led to t following conclusions: (1) That almost all cases eclampsia sustained renal damage, as shown by a diminished power of excretion and of concentrati of urea (MacLean's urea-concentration test), and a high blood-urea. The concentrating power the kidney varied at different stages of the illne and might greatly improve as the patient's gene condition responded to treatment. The normal bloo urea in the second half of pregnancy was abo 16 mg. per 100 c.cm., while that of the average eclamp patient was twice as high (32 mg. per cent.). T higher the blood-urea the worse was the progno in most cases. (2) That the tests of renal functi were of doubtful value. The large majority of ca showed definitely impaired excretory power wh tested by Rosenthal's method (intravenous injecti

a known quantity of phenol tetrachlorphthalein, d the estimation of the amount of dye removed m the blood stream by the liver in a given amount time), and almost half the cases of eclampsia d a positive van den Bergh and a positive Fouchet action. These results had apparently little bearing the clinical aspects of eclampsia and were of little gnostic value.

Dr. H. S. DAVIDSON referred to the high mortality cases with low blood pressure, and thought that is might be due to a profound affection of the yocardium by the toxæmia, thus lowering the blood essure. He referred to the small number of deaths m heart failure associated with shock and collapse, ich bore out the importance of non-interference the ordinary case of eclampsia. He made special erence to the number of deaths from pulmonary lema and wondered whether œdema was directly ceable to the use of ether as an anæsthetic or ether it was just part of the general œdema. It came a question whether, when an anæsthetic was quired, chloroform should be given as suggested Stroganoff or whether some other form of narcosis, ch as gas and oxygen, should be adopted. It was ry difficult to carry out the Stroganoff treatment hospital, and he could find no good purpose served venesection which could not be as efficiently rved by veratrone. Dr. Davidson referred to the eatment of eclampsia by intravenous injection of agnesium sulphate which he had been trying for the st six months with good results, although up to date ly eight cases had been treated. Magnesium lphate acted as a sedative and anticonvulsive agent d produced a marked elimination by causing a rge increase in the urinary output. This was llowed by a marked diminution of œdema which was obably general and affected the brain as well as her tissues. He concluded by considering the eatment of the fulminating type of eclampsia and oke of the bad results obtained by any conservative ethod of treatment on such cases. He thought at by Cæsarean section the prognosis might be nproved in these cases.

Reviews and Notices of Books.

EUROLOGY.

Degeneration and Regeneration of the Nervous System. By S. RAMON Y CAJAL, M.D., F.R.S., Director of the Instituto Cajal, Madrid. Translated and edited by RAOUL M. MAY, Ph.D. Harv., D. ès Sc. Paris. In two volumes. London: Humphrey Milford, Oxford University Press. 1928. Pp. 769. 50*s*.

THE scientific work of Prof. Ramon y Cajal is nown wherever neuropathology is studied or stology taught; at one time or another every edical student has become familiar with his name; it hitherto the results of his labours have appeared ly in Spanish. An English edition, in two volumes, that corpus doctrinæ which was awarded a Nobel ize is sure of widespread appreciation. Yet at the st glance its appeal may seem somewhat limited. rgely by the application of a histological technique hich bears his name, Prof. Cajal has devoted his udies to the problems of the degeneration and generation of the neurone, and begins by showing at the long controversy as to the continuity or scontinuity of that structure is finally settled favour of the former. How much in reality has pended on this solution those can appreciate best ho understand that theories of trophicity and coverability of tissue are based on the behaviour the individual neurone under pathological conditions. he next step is to take the reader through a long ries of investigations dealing with the reaction of the urone to lesions of sensory and sympathetic ganglia, spinal cord and roots, cerebellum, and cerebral cortex respectively. In each instance the phenomena of degeneration are examined with an infinity of care, as regards both peripheral and central elements, and the differences between the attempts at effective regeneration at various levels are fully illustrated. Indeed, it is remarkable that at lower levels (peripheral nerves and even spinal cord) a very fair effort at self-regeneration is accomplished by neuronic activity, under propitious circumstances, whereas in the brain attempts to innervate the cicatrices of trauma appear always to be lacking. Nor in this latter instance is there anything to hope from the beneficial effects of time. The deficiencies preventing restoration have been discovered by Prof. Cajal, who has shown that the outstanding problem is the supply of adequate nutritive material to stimulate and invigorate the indolent and scanty growth of neuronic sprouts.

The more one probes, under the leadership of such an authority as Prof. Cajal, into the minutiæ of neuronic existence the more clear does it become that the general trend of this remarkable research is towards the mysteries of cell-life. The sensitivity of the neurone to harmful agencies is the other side of its marvellous capacity for the delicacies of neural function; more than any other tissue in the body it is responsible for heredity, adaptation, and growth. Histological study of the kind here pursued can never be too painstaking, since in the activities of the cell we touch the unknown and elusive arcana of life itself.

The A B C of Nerves. By D. F. FRASER-HARRIS, M.D., D.Sc., F.R.S.E. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 1928. Pp. 223. 4*s*. 6*d*.

IF there is such a reality as an A B C of nerves its exposition in Dr. Fraser-Harris's hands can be trusted to represent accepted physiological fact dressed in a pleasantly readable and literary garb. We may assume, perhaps, that in the view of some moderns the idea that a little learning is a dangerous thing is démodé, and that the more difficult, complex, and intricate a subject is the more will certain minds deceive themselves into supposing that a superficial acquaintance with it makes up for their inherent incapacity for grasping its profundities. We are glad that Dr. Fraser-Harris recognises the impossibility of distinguishing between what is elementary and what advanced in respect of the nervous system, and we note that he admits the constitution and functions of that system are so little matters of common knowledge that practically nothing of its physiology is known to the ordinary reader. Frankly, neurology is a technical subject, just as much as the law. If anyone wishes to ascertain some of the elements he can scan this primer with advantage. Criticism of what must have been a distinctly arduous task—viz., to teach the neurological alphabet to non-medical reader—is not called for.

RODENT FLEAS AND PLAGUE.

Rongeurs et puces dans la conservation et la transmission de la peste. By RICARDO JORGE, Director of Public Health, Portugal; and E. ROUBAUD, Professor of Entomology, Pasteur Institute, Paris. Paris: Masson et Cie. 1928. Pp. 306. Fr.30.

THIS work is the outcome of a vast inquiry (1924–27) undertaken, with the help of various nations, by the Office International d'Hygiène Publique and Prof. Roubaud was asked to complete the work with a systematic description of rodent fleas, with drawings and photographs. Of these illustrations it may be said that they are as good as such things can be, and they will be useful for purposes of identification where actual specimens are not available. When the true cause of plague was discovered and the disease was placed on a scientific foundation attention

was mainly concentrated upon rats and mice. As time went on it was found that all rodents were liable to suffer from plague and might be, more or less, carriers of the plague bacillus. Even the section containing hares and rabbits is not exempt. A few years ago two hares and two rabbits were found suffering from plague, probably caught from rats, in Suffolk, and *Ochotana daurica*, the "rat-hare," is frequently found infected in East Russia and Trans-Baikalia. In Siberia, China, and elsewhere the marmots suffer from epizoötics and often start epidemics. Of these the most dangerous is the large marmot, *Arctomys bobac* (the tarabagan). Not so very long ago 70,000 persons died of pneumonic plague in Manchuria, which began among the trappers who hunt this marmot for its fur. In North America ground squirrels are a danger, and in South America the wild *Cavia aperca* has been found carrying *Pasteurella pestis*. In Africa epizoötics occur among gerbilles and other wild rodents that are attracted to villages and farms in search of grain and may thus become a danger to human beings. These are only a few examples out of the many recorded in this book. But it is still the rats, *M. rattus*, *M. decumanus*, and *M. alexandrinus* that give the most trouble. They breed rapidly and have become "domestic" in houses, barns, and sewers. They also travel to and fro in ships. Any infected ship's rats may not only cause an outbreak of plague on the ship itself but they may also infect other rats or mice in the ports which the ship visits. Following the general and very complete summary by the chief compiler there are good plates showing the tarabagan, the spermophile, the souslik, the ground squirrel, the gerbille, and the multimammate mouse. Among the fleas that convey plague from animal to animal, or from a rodent to man, no doubt the most important are the rat fleas of the genera Ceratophyllus and Xenopsylla. Of the latter genus *X. astia* does not appear so dangerous as the other species. Many fleas die of suffocation during an epizoötic owing to the rapid growth of the bacillus, and it is not every infected flea that transmits infection; but, generally speaking, it can be said that all species of fleas found on rodents are capable of transmitting plague. *Pulex irritans*, the human flea, and others can also transmit infection. Annexed to Prof. Jorge's general summary are some reports reproduced from the monthly *Bulletin* of the International Office. They come from Great Britain (1924), Italy, South America, South Africa, the Soviet Republics, China, Japan, &c., and are worth reading as containing much information concerning the local rodents and fleas as well as notes on epidemics and prophylactic measures. The last 56 pages contain systematic descriptions, by Prof. Roubaud, of 35 rodent fleas, and 50 more are mentioned but not fully described. Seven excellent plates show many of these fleas. An index of rodents and fleas is provided. We can recommend this book as both interesting and useful.

VARICOSE VEINS.

Varicose Veins and their Treatment by "Empty Vein" Injection. By RONALD THORNHILL, M.B., Ch.B. London: Baillière, Tindall and Cox. 1929. Pp. 63. 5*s*.

The Treatment of Varicose Veins by Intravenous Injections. By J. D. P. MCLATCHIE, M.D., C.M., Physician, Western Skin Hospital. London: William Heinemann (Medical Books), Ltd. 1928. Pp. 51. 3*s*. 6*d*.

THE growing interest in the injection treatment of varicose veins is reflected in the increasing number of books devoted to the subject. Sir Berkeley Moynihan, in his foreword to Dr. Thornhill's book, writes: "In surgery the search is always for simplicity. Complicated and cumbersome methods which are inherently dangerous give way by degrees to simpler and safer procedures. In surgery, as in the other arts, the easy way is often the outcome of long experience and of trial and error." These words should do much to allay the fears of those who are still prejudiced against the use of intravenous methods in the treatment of varicose veins. The author is a follower of the quinine school, though, of course, using other solutions in cases where this particular drug is contra-indicated. His technique consists essentially in the introduction of the solution into the lumen of the vein when this is devoid of blood, and a full account of this procedure is given. It is claimed that adequate thrombosis can be obtained by using not more than 1 c.cm. of the solution. As regards the complications of the method it is admitted that despite the most rigid precautions sphacelus will occur in a small percentage of cases. Some account of the general reactions which may be produced by quinine should have been discussed. In considering the treatment of cases who have had phlebitis the author very wisely urges caution. For cases of varicose ulceration Humbert's method of using Unna's paste is advocated, but no critical account of the limitations of associated injection treatment is included. The book is enhanced in usefulness by the fact that the writer has been content in the main to concentrate on only one method, and to mention other methods but briefly. Ten illustrative cases are considered in an appendix.

Dr. McLatchie, after a short historical account of the development of injection treatment, describes the technique he employs in using the various sclerosing solutions. He prefers in general the sodium salicylate method, but uses the quinine and urethane solution in certain selected cases. Of the last-named solution doses up to 6 c.cm. are advocated; it is found in practice, however, that local and general reactions to doses of this size may be rather severe. The question of the advisability of giving injections immediately after the subsidence of an attack of acute phlebitis is highly debatable, since the risk of lighting up the infection is no small one. The safer course is to wait for an interval of at least six months after the phlebitis has cleared up before considering the question of injection treatment. Disregard of this rule has in the past certainly led to accidents. It is to be hoped that in future editions much more stress will be laid on "white leg," since it is by far the most important contra-indication met with in practice to injection methods. Only too often patients with this condition are sent up for treatment. An inclusion of the author's experience in dealing with the various types of varicose ulceration would have been valuable, for it must be conceded that not all cases respond equally well. The book is well written and should prove a useful introduction to the practitioner wishing to take up injection treatment. A considerable bibliography is appended.

COMPARATIVE ANATOMY.

Vertebrate Zoology. By G. R. DE BEER. London: Sidgwick and Jackson. 1928. With 185 text-figures. Pp. 505. 15*s*.

ZOOLOGY was at one time taught by going through the systematic catalogue of animals—their phyla, families, genera and species. Huxley and Martin introduced the type system in which a few examples are studied in detail and compared with one another. Both methods have their advantages, and Mr. de Beer has combined them in a novel way which should be fruitful. He first describes the anatomy of nine vertebrate types and the development of amphioxus, frog, fowl, and rabbit. He then takes each system (blastopore, skin, tail, brain, ductless glands, &c.) and discusses their varied representations in vertebrates. Finally, he weaves the whole together in a most interesting discussion of evolutionary morphology in which structure, function, and history combine to make one of the noblest tales which man has put together.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 2, 1929.

THE MEDICAL EDUCATION OF WOMEN IN LONDON.

THE Committee on the medical education of omen undergraduates submitted last week a report [1] hich has received the general approval of the enate of the University of London. After a careful irvey of the evidence derived from the authorities the London medical schools and from various ganisations indirectly interested, the Committee ate as the first of their well-considered conclusions: We are unable to see any valid argument . . . gainst the provision of co-education in medicine." he very form of these words shows that their attitude as been critical and that they have approached the ubject from a practical standpoint. The points in difficult story may be recalled. Some 12 years ago rtain London medical schools opened their doors women students, some without consulting the enate, and all but one have closed them again without xplanation. The natural corollary of this withrawal from what seemed a progressive policy on the art of constituent schools of a university whose prepossession . . . is in favour of such coducation" is an inquiry into the reasons which oved the authorities of the schools to change their iews. Was it, for example, because difficulties arose connexion with the conduct of, or accommodation or, the new-comers? Or was it because the men udents applying for admission to every one of the ixed schools became so numerous after the war at some of them would have had to be refused if omen applicants had been accepted? Which, in ort, of the many reasons which might have led to is reversal of policy did in fact lead to it, and was the same reason in every school? The answer iven in the report seems clear:—

"The real difficulties arise from (*a*) the multiplicity of edical schools and their competition for students; and) the feeling against co-education entertained by some of e men already in the medical profession, some of the en students, and a section of the public. With few xceptions the authorities of the medical schools appear be convinced that men, if they have a choice, prefer to to schools which do not admit women, and that the eling is strongest among the men, and in some cases the arents of the men, who on general grounds would be most esirable. Since there are now certainly not enough udents to fill all the schools, this means if some schools dmit while others exclude women, that co-education is an unstable equilibrium, and that the school which dmits any women will have a disappearing number of en."

That this antipathy to co-education exists in some uarters must be admitted. The attitude of the oung men is comprehensible, when we think for a oment of the deep-seated tradition upon which is based—and that is what has to be borne in mind. Only those who forget it point, as though with a decisive finger, either to jealousy, academic or economic, or to rivalry on the playing-fields as being the real motives of the reluctance of young men to join the mixed school. These may fortify the attitude, but it is produced by more fundamental things and has to be reckoned with. Since the Dean is the business head of the school under his care, it is his duty to see that a good type of youth is not discouraged from selecting a particular school by any factor that disturbs the instinct towards sex separation that is developed among young men in the public schools, and perhaps fostered in them by a university career. The natural reaction from the war period, when women invaded so many spheres previously sacrosanct to men, was to emphasise for a time a desire to revert to pre-war ideals—a reaction that has been manifested in many spheres of thought and activity. This may be a passing phase, and there are signs even now that the prejudice against co-education in medicine, as against cöoperation between men and women in other directions, is lessening. The medical student ultimately will have to accept among his colleagues, whether in private or general practice, in the public health services, or in the laboratory, a proportion of women. Is the association to begin when he leaves his public school, or when he commences his professional work? The Committee hold that co-education forms a valuable training for the coöperation which in their subsequent careers becomes necessary between medical men and medical women, though their comment that the advantage is felt less by men students than by women students is, as yet, supported by facts.

Not only for the practical reasons set out in the report, but for more subtle ones, the provision of co-education cannot be coerced; if it is to be successful it must be not only a permissive reception, but a cordial welcome. In proportion as the women at any medical school are received as part of the corporate body and given adequate chances of post-graduate employment, their careers have been creditable to the individual school and to the university to which it is attached. The Committee has now cleared the ground. It must be left to the individual schools to see whether too much permanent importance has not been attached to a natural post-war phenonemon. To read the signs of the times is not easy, and to prophesy is even less easy. But there is evidence that those signs are changing in such a way as to enable the authorities of the medical schools in London to welcome back the women students without risking the defection of the young man with fine traditions, even though those holding the contrary view are more vocal in expressing their sentiments.

[1] The report is set out in full on p. 251.

THE ENCEPHALOMYELITIS OF MEASLES.

RECENT epidemics of post-vaccinal encephalitis have aroused a renewed interest in other uncommon forms of acute encephalitis, especially those complicating the exanthemata. These serious complications of the specific fevers have been familiar to clinicians for over a century, but it is only lately that careful histological examination of the nervous system has been made in fatal cases, and that the ætiology of these conditions has been seriously considered. Two recent contributions to our knowledge of the subject have been made by Dr. F. R. FORD,[1] who reports

[1] Ford, F. R.: Bull. Johns Hopkins Hosp., 1928, xliii., 140.

12 fresh cases of "the nervous complications of measles," and Dr. J. G. GREENFIELD,[2] who has made a pathological examination of a fatal case.

Dr. FORD, reviewing the literature, finds 113 cases of nervous symptoms complicating measles, in addition to the 12 he reports himself. The onset is usually on the fourth to the sixth day of the illness, after the fever has fallen and the rash has begun to fade. Dr. FORD distinguishes the following clinical types: (1) A mild and transient disturbance characterised by stupor, headache, meningeal signs, and sometimes convulsions, a clinical picture resembling "meningism" or "serous meningitis." These cases are characterised by the absence of focal signs and by prompt and complete recovery. (2) A group with multiple focal or diffuse lesions of the nervous system. These cases may show symptoms of lesions of the cerebral cortex, the basal ganglia, brain-stem, cerebellum, and spinal cord, and as might be expected, overlapping of symptoms renders exact classification impossible. Complete recovery occurred in 14 out of 42 cases of this group. Residual mental defect occurred in 15, some disturbance of motility in 11, epilepsy in 4, and narcolepsy in 1. Five patients died. (3) Single focal cerebral lesions. Of these, hemiplegia and aphasia are the commonest. Of 27 patients in this group 8 recovered completely and 1 died, the remainder being left with hemiplegia. (4) Cerebellar syndromes occurred in 14 patients, in 12 of whom recovery was incomplete. (5) Paraplegia and spinal cord syndromes. These may occur with or without concurrent involvement of the brain. The clinical picture in this group is an acute ascending paralysis. Of 33 patients 6 died and 15 recovered completely. (6) Other nervous complications are rare, the least uncommon being toxic psychoses. Papill-œdema may occur. The cerebro-spinal fluid usually shows a moderate increase in lymphocytes and protein, but may be normal. Dr. GREENFIELD'S pathological investigation confirmed the findings of other workers that the most characteristic change in the nervous system is a zone of demyelination (loss of myelin sheaths) around many of the small veins. These areas are infiltrated with leucocytes, which in early cases may resemble lymphocytes or polymorphonuclear cells. Later fat granule cells and swollen neuroglial cells are to be found. Cellular infiltration of the perivascular sheaths is an inconstant feature. There is great vascular congestion and multiple small hæmorrhages may be present. These pathological findings have received different interpretations. Dr. GREENFIELD regards them as evidence of inflammation, but Dr. FORD describes them as a "toxic degenerative rather than an inflammatory process." Dr. GREENFIELD stresses the clinical and pathological similarity of the disease to post-vaccinal encephalitis, and takes the view that encephalitis complicating measles is due not to the virus of measles, but to a special neurotropic virus which resembles, if it is not identical with, the virus responsible for post-vaccinal encephalitis. It will be noted that Prof. J. C. LEDINGHAM, introducing an important discussion last Friday at the Royal Society of Medicine (see p. 231), remarked on the tenability of a theory which presupposed the activation of some latent neurotropic virus in post-vaccinal cases.

We publish in this issue a clinical and pathological report on "six cases of acute meningo-encephalomyelitis of childhood," by Dr. RUSSELL BRAIN, Dr. DONALD HUNTER, and Prof. H. M. TURNBULL. The authors stress the clinical resemblance between their cases and cases of post-vaccinal encephalitis and encephalitis complicating the specific fevers, and it may be remarked that Dr. BRAIN and Dr. HUNTER'S six patients exhibited among them four out of the five clinical pictures described by Dr. FORD as occurring in the encephalomyelitis of measles. The pathological picture in the fatal case, however, was that of a profound toxæmia, and the nervous system showed neither perivascular demyelination nor leucocytic infiltration. This case, however, was an extremely acute one, "meningeal" in type, and it is possible that the less acute cases exhibiting clinically diffuse focal involvement of the brain would have shown different pathological features. These cases naturally raise the question whether they may have been due to the same hypothetical virus which has been held responsible for post-vaccinal and other similar forms of encephalitis. The pathological evidence is for the reason indicated inconclusive. Moreover, assuming that a virus may sometimes operate alone and sometimes as a secondary invader, we do not know whether the same pathological picture is to be expected in both circumstances. For the present we must be content to suspend judgment on this point. The problem is one, as Prof. LEDINGHAM said, which can only be solved by further experiment, and it is to be hoped that the publications cited will lead to a more widespread recognition of obscure forms of acute meningo-encephalomyelitis, so that thorough clinical, pathological, and bacteriological investigations may be carried out on a large number of cases.

ABORTION, CRIMINAL AND OTHER.

THE criminal statistics of the offence of procuring abortion seem almost reassuring. The latest figures are those for Scotland in 1927; in that year eight cases came to the notice of the police and resulted in the conviction of three women. The last English figures are those for 1926; they show 41 such charges tried. The annual averages for the quinquennial periods from 1900 to 1925 in England begin with 11, 20, and 30—a steady climb. In the war period there is a jump to 43; in the period 1921–25 a slight decline to 37. That is one side of the picture. It suggests that criminal abortion in Scotland is almost negligible and in England by no means grave—in both countries a far rarer offence than murder. The other side is painted very differently by speakers at a recent meeting of the Medico-Legal Society (reported in another column), who declared that abortion is undoubtedly increasing and that 25 per cent. of the cases are criminal. The difficulties of prosecution are notorious. No evidence is forthcoming from the woman who has courted the dangers of abortion; if a professional abortionist has been at work, he has taken every precaution of secrecy; if a medical practitioner believes that his patient has broken the law, his professional respect for her confidence debars him (except in the event of death) from informing the police—indeed, even if he were at liberty to make disclosure, he has usually nothing but suspicions to communicate. Suspected abortion is one of the causes of death for which the registrar must watch vigilantly with a view to referring the case to the coroner. The medical practitioner's certificate or refusal to certify may be significant, but we can hardly hope that the Registrar-General will be able to furnish us with exact or trustworthy statistics from this source. If the recent speakers are right, the law is being broken freely and with

npunity. Competent judges aver that the law in self is adequate; it is the enforcement which is at ault. Some reformers would welcome a more igorous attack upon the traffic in abortifacient rugs. They point to the shameless and unrestricted dvertisement of preparations which claim to "remove ll female obstructions, however caused," and which, s LORD RIDDELL has observed, must be either auds or abortifacients. They advocate the suppression of such advertisements by statutory prohiition for which a precedent exists in the Venereal)isease Act of 1917; this is a matter which might ell be pressed upon the attention of the Home)ffice. Another suggestion, to restrict the use and upply of lead and other abortifacient drugs by xtending the schedules of the Poisons Act and)angerous Drugs Act, requires more caution. Many rugs used for the purposes of abortion are also equired for purposes entirely innocent. Moreover, o make drugs less easy to obtain may merely have he result of driving abortionists into a more frequent se of instruments or electrical treatment. The resent difficulty of enforcing the law is significant; ould a more rigorous law obtain better results? he prospects of improved legislation must certainly e explored, but too much is not expected of an ct of Parliament.

No remedy will succeed without the support of ublic opinion, which for this purpose means largely he opinion of women. Does public opinion condemn bortion as vigorously as heretofore? Those who re in a position to know tell us that women, married nd unmarried, demand abortion often without being onscious of any moral or legal offence. Birth control, owadays canvassed without the old reserve, is ssentially distinct from abortion; but the change of iew towards birth control may be a symptom or an ncouragement of other changes. Are we coming o a time when prudential considerations will be eemed to justify the interruption of pregnancy, t any rate in its early months, as though this were nerely an extended form of contraception? Soviet Russia has legalised abortion upon condition that a nedical commission approves and that the operation s performed by a doctor in a public hospital. What re the consequences to the health of the mother nd to infant mortality? We lack the positive nowledge which would provide a medical contriution to a moral question; the pursuit of evidence s distracted by non-medical issues. Yet it is to the nedical profession that the public will look for uidance. At present, unfortunately, some reformers ook askance at that profession, accusing it of shielding he abortionist by maintaining its ancient tradition of ecrecy.

Annotations.

"Ne quid nimis."

THE KING'S HEALTH.

IT is significant that the bulletin issued on Friday f last week was the first official intimation concerning he health of the KING that had been made public for our days, and the abatement of perpetual anxiety vas at once recognised. That bulletin informed us hat, while improvements previously noted continued, acteriological examination showed the right chest o be free of the infecting organism. On the following lay a bulletin, signed only by Lord Dawson, confirmed record of slow progress, and the one which appeared on Wednesday announced a further gain in strength. The story therefore is now one of steady improvement, although, after the ordeal which has been passed, that story may be a prolonged one. But it is legitimate to hope that the strides forward will become more rapid within the salubrious environment provided on the south coast.

THE LIGHTING OF SCHOOL BUILDINGS.

A REVIEW of the current practice of the lighting of school buildings in the United States has recently been published by Mr. James E. Ives, physicist to the Public Health Service, in which the codes of requirements specified by the education authorities in 39 of the States and 9 of the principal cities are set out. So far as natural lighting goes, the main recommendations concern the ratio of window area to floor area, unilateral or other lighting by windows, preferred exposure of windows and height of windows above the floor. The primary necessity is for the quantity of light to be sufficient, and in this connexion it must be borne in mind that the colour of the walls in the class-room must have a larger or smaller effect in absorbing the light entering by the windows. The best test is whether or not the lighting is sufficient on a dull winter's day for a normal or optically corrected eye to read the 6/6 line on the standard test-type easily at six metres. As a rule 1 sq. ft. of glass for every 5 sq. ft. of floor space is sufficient for this purpose, but this should be a minimum and it must always be remembered that the height of surrounding buildings must be taken into account. The direction of the lighting should always, where possible, be from the left in order that the shadow of the child's hand should not interfere with the light on the paper when writing. For the same reason cross-lighting and sky-lighting are undesirable. With regard to the exposure, it is rather remarkable that the majority of the American authorities prefer any aspect to a southerly one. For warm climates an east, west, or even north aspect may be preferable, but it is certainly most desirable that, if possible, the class-room during some part of the day should be bathed in sunshine. If necessary, during hot weather the windows can be shaded, and in any case the desks should be arranged so that neither children nor teachers face the windows. An important recommendation of the American authorities is that there should be a distance of from 4 to 8 ft. from the front wall of the room to the first window on the left-hand side of the class-room. It must never be forgotten that, so far as general health and mental alertness go, the nearer the conditions of the class-room approximate to those out of doors the better, and in this connexion the access of the ultra-violet rays through special glass, in cases where the expense is not prohibitive, must be recommended. The first essential for the school-room is the admission of sufficient light without the dazzling effect of direct sunlight on the children's eyes, for without sufficient light or with the dazzling effect of direct sunlight the tendency is to cause the children to stoop and develop myopia and round shoulders. While the avoidance of dazzle is of the first importance, we are of opinion that it would be mistaken policy to secure it at the expense of depriving the children of the tonic effect of direct sunlight in the school-room during some part of the day on those comparatively rare occasions when it is possible to obtain it in this country. For this it might be considered worth while to sacrifice, where necessary, an arrangement of windows which from the point of view of ocular hygiene alone might be ideal. With a little trouble it is possible to shade south windows or even sky-lights by suitably coloured blinds on a hot summer's day. With regard to artificial lighting, there is no objection to electric lights so long as proper precautions are taken against the dazzling effect of unshaded lamps which in any case should be placed well out of the ordinary line of vision.

SUBMUCOUS RESECTION OF THE NASAL SEPTUM.

TWENTY or twenty-five years ago, before submucous resection was generally adopted, deviations of the nasal septum were treated by cutting and breaking the bony and cartilaginous framework of the partition, with subsequent splinting, and by sawing off the prominence of a vomerine ridge or spur. These operations were useless for all but the more simple forms of deviation, and they did not remove the general thickening of the septum often seen in traumatic deflections; many surgeons therefore contented themselves with removing large portions of the inferior turbinal bone on the side of the convexity so as to make room round the obstruction. All these methods were often unsuccessful in curing the nasal obstruction, whilst the damage done to the nasal mucous membrane was liable to cause crusting and even atrophic rhinitis. Those who practised rhinology at that period, and remember the unsatisfactory treatment of obstruction due to septal deviations, are in a position to realise how much better are the results obtained by submucous resection—an operation which is capable of dealing with any shape of contorted and thickened septum, and of correcting the deformity without damage to the nasal mucosa, whose preservation is necessary to the proper performance of the functions of the nose.

Like other operations, however, its results are not uniformly successful, and it has occasionally suffered from the excessive enthusiasm of its devotees. Its primary object is the removal of mechanical obstruction due to deviations and thickenings of the cartilaginous and bony structures forming the septum, and in considering this indication it should be borne in mind that no one has an absolutely straight septum, and that the slighter degrees of deflection do no harm. Even considerable deviations running parallel to the path of the air-current, such as the common vomerine ridges, may cause little or no interference with respiration, and before operation it is essential to make a careful diagnosis of the cause of the obstruction, which may be vasomotor engorgement or alar collapse rather than a moderate degree of septal deformity. A good result is, of course, far more problematical when the operation is undertaken, not for obstruction, but for the relief of some more remote affection thought to be secondary to the septal deviation; among these may be instanced middle-ear deafness and the reflex disturbances believed to produce or aggravate such conditions as asthma and hay-fever. Submucous resection undoubtedly gives very great benefit in some of these cases, but great caution is advisable; for instance, it should be quite certain before operating that the deafness is of the middle-ear catarrhal type, and not due to otosclerosis, and where there is no marked nasal obstruction the surgeon must be clear that there is chronic nasopharyngeal or tubal congestion which may reasonably be ascribed to the deviation of the septum.

In the operation itself any imperfection of technique is liable to leave bad results. When the deflection extends well forwards a common mistake is to make the incision too far back, thus leaving a septal prominence opposite the narrow part of the ala. More unfortunate, because more difficult to remedy, is the removal of too much of the support of the tip of the nose. Where the deflection extends to the extreme antero-superior margin of the septal cartilage under the bridge of the nose the operation must be a compromise, some of the deflected cartilage being left in order to provide support; in severely smashed noses with much deformity a complete resection must sometimes be performed in order to provide an adequate airway, and must be followed by a plastic operation. At the apex of sharp projections, and in the corresponding receding angle on the opposite side, the mucous membrane is apt to be extremely thin, and a perforation of the septum is easily caused. In such a situation Dr. J. L. Curtin,[1] of Dublin, advises leaving a piece of cartilage attached to the top, front, or floor of the septum, whilst other surgeons place an unattached piece of cartilage between the flaps to cover a thin patch or a perforation, and find that the graft usually takes readily. Dr. Curtin also recommends that the vertical incision be prolonged upwards and backwards to give more room, and he claims that this, when necessary, is less liable to retract and to require suture than the more usual prolongation along the floor of the nose. He is strongly opposed to the use of the Killian long speculum, which, in his opinion, unduly stretches the flaps, takes all the elasticity out of the membrane, and is the chief cause of "flapping septum." Very rightly he notes that more should not be removed than is necessary to give a good result, but he will not find general agreement with his practice of removing the basal ridge with saw or chisel at a subsequent occasion. Operations at two sittings are harassing to the patient, and should only be undertaken when good results cannot safely be obtained at one.

WINTER IN MERAN.

MANY years ago the well-known geologist, Dr. C. W. Fuchs, compared the winter climate of Meran to that of summer in high Alpine valleys. From December to March the nights are like those of winter, but the days resemble those of a warm spring. Fuchs was not the first to discover the attraction of the smiling valley of the Alto Adige, protected as it is on the north by mountains more than 9000 feet in height, and falling gently to the south with a sunny exposure in which the rocks absorb the heat by day and radiate them back after sunset. Although only some 1000 feet above sea-level Meran is among the driest spots in Europe, with a clear and serene air especially noteworthy in the winter. The claims of Meran to the notice of those in search of favourable winter conditions were laid before the International Conference on Tuberculosis which took place last October in Rome; for up to the end of the eighties Meran had developed chiefly as a resort for tuberculosis. This was, of course, before the High Alps were popularised by the teaching of J. A. Symonds, Alexander Spengler, and Theodore Williams; but, although the younger and hardier of tuberculous invalids may be right in seeking the high altitude, the winter climate of Meran, as Dr. A. W. Schmidt pointed out to the Conference, is well adapted for those with weak hearts as well as for convalescents and prophylactics. Its natural attractions are supplemented by hydropathic institutes provided with baths and gymnastic apparatus and the like, while, in accordance with Tirolese practice, the living-rooms have retained their comfortable Swedish stoves after the hotels and pensions adopted the principle of central heating. It is just a century since the Bürgermeister, Josef Valentin Haller, began to lay out the town in keeping with the natural beauty of its surroundings, and that Meran has been visited by kings and queens, as may be inferred from the writings of the novelist, Paul Heyse. The Vienna bank crash of 1872, coming shortly after the opening of the Brenner railway, arrested for a while the crop of new buildings and helped to prevent the hasty modernisation which has marred many another popular resort. Dr. Schmidt draws an exhaustive comparison between the humidity, temperature, and insolation of Meran in the winter months with those of Alpine resorts and of certain places in the lowlands. He makes much of the fact that the sun temperature may reach 80°, or even 100° F., at noon in mid-winter, while the fall in the night-time and early-morning, it may be to freezing, is "absolutely of no interest for our clients." Some of the other resorts might draw other deductions from his data, but he is no doubt on safe ground in claiming a great increase of metabolism from a sojourn in Meran in the winter, which may

[1] Jour. of Laryng. and Otol., January, 1929.

eadily lead to absorption of pleuritic exudates and o retrogression of certain anatomic lesions. Wind s the great bugaboo of the subalpine resort, but while n spring and autumn violent winds may occur ccasionally for a few hours, the place is nearly ind-free in the winter months, while the soil is so orous that the scanty rain disappears quickly, and isitors can promenade dry-shod. Dr. Schmidt's omplaint is rather that these visitors find themselves o much at home in the climate that they are apt to conomise on medical advice and to behave in an rational manner, especially in regard to the wrong se of sun baths. Abuse of solar radiation has often, e says, led to harm when active pulmonary disease s present or when the epithelium of the kidneys s damaged ; in the latter case albuminuria or hæmauria may result. One of his practising colleagues, Dr. Hans Matscher, tries to put into words a sympathetic feature which makes Meran so pleasant as a ealth station. This is the happy nature of the nhabitants. The *Burggräfler*, as the native technically is called, lives and eats both wisely and well, nd likes others to do the same. It is evident that Meran should not be forgotten in the choice of a vinter resort.

"OPSONISED" SALICYLATE IN THE TREATMENT OF RHEUMATIC FEVER.

It is well known that washed leucocytes manifest no phagocytosis, but that if a drop of serum is added o them they ingest any microbes in their vicinity. Dr. Kalinin and Dr. Müller, working with Prof. S. D. Belonowsky at Leningrad, have found that he treatment of experimental orchitis by injection of a culture of pneumococci into the testis is greatly improved if optochin is added to the vaccine, nd that experimentally produced meningitis can be avourably influenced by the use of a vaccine combined with chemotherapeutic substances, such as urotropine or manganese. Levaditi has shown that bismuth acts more energetically on the spirochæte f it is previously treated with liver extract. The view that this is due to "opsonisation" of the bismuth is supported by Kritchevsky's experiments, showing that the action of salvarsan is strengthened by combining it with the serum of a syphilitic patient. Pursuing this line of investigation, Dr. A. A. Balkovsky, of Leningrad, conceived the idea of using "opsonised" sodium salicylate for acute rheumatic fever, as Prof. Belonowsky had used opsonised quinine for malaria. The experiment was made on 35 soldiers, aged between 20 and 30, admitted to a military hospital with acute polyarthritis, high fever, and general malaise. The inflammatory process moved rapidly from one joint to another; the joints affected were swollen and the skin over them was inflamed. Any movement caused intense pain, which was only relieved by narcotics, and often there was an exudation in the joint cavity. Some of the patients developed endocarditis in the first or second week of their illness. The method of treatment was as follows: Into a 20 c.cm. record syringe were drawn, first, 5–8 c.cm. of a sterile 20 per cent. solution of salicylate of soda and then 8–10 c.cm. of blood from the median basilic vein of the patient. After three or four minutes the contents of the syringe were re-injected into the vein, without removing the needle from it. No reaction was produced, provided none of the solution leaked into the subcutaneous tissues. The dose was repeated daily or at intervals of two or more days, according to the severity of the case. Many of the patients recovered after one or two injections, while others required as many as 8 or 12. No other local or general treatment was given to these patients, and—except for one case of temporary jaundice—all recovered without incident. Three-quarters of an hour after the injection they would feel much better and happier, and sleep was obtained without narcotics. The temperature usually dropped, but the pulse and blood pressure remained unaltered. On the second day after the injection a marked improvement was visible, both in the subjective condition and in the inflammatory process. During the observation period of two to three weeks there were no relapses. The method, according to its author, compares very favourably with ordinary treatment. It is absolutely harmless and in many instances served to abort an attack of polyarthritis. It limits the severity of the illness, hastens recovery, and reduces the incidence of complications. Its analgesic effect obviates the use of narcotics. Control experiments in which plain sodium salicylate was administered intravenously showed that it was, in fact, the "opsonising" process which distinguished this method from the ordinary oral administration of the drug.

POISONS IN BENGAL.

The work of an Indian Government analyst is never lacking in interest, and the annual report of the chemical examiner to the Government of Bengal for 1927 bears testimony to the extraordinary variety of material which passes through a laboratory of this kind. The diversity is particularly noticeable in the present instance because the analysis of excisable drugs was taken over from the excise department during the year, and a considerable amount of additional work has had to be undertaken on that account. Reorganisation is evidently the order of the day in the chemical department, and one result is to be seen in the addition of non-medical scientists to the staff. This change is not without a general significance, and perhaps marks the approaching end of the periods during which the doctors have been made use of for scientific duties which were not strictly medical. In view of the considerable amount of work of a non-medical nature which has now to be dealt with in a public analyst's laboratory, the innovation seems reasonable, and it is an encouraging sign of the advance of general scientific education in India that graduates in various branches of science are now readily available.

In the year under report 7557 articles were investigated by the Bengal chemical examiner's department. This number shows an increase of 536 over the previous year, and the examinations include medico-legal work, analyses of foodstuffs under the Food Adulteration Act, the standardisation of drugs, and miscellaneous analyses of various kinds. The medico-legal examinations show the usual features of an Indian list. The total number of cases referred to the department was 2112, and in a large proportion of these poison was detected. In human poisoning opium heads the list, and the next in order of frequency—apart from alcohol—are arsenic, oleander, and aconite. One body in which arsenic was discovered was removed from a funeral pyre by the police in a charred condition. This illustrates a frequent difficulty in medico-legal work amongst Hindus, whose ordinary method of disposal of the dead is by cremation, but it is noted that arsenic, though a volatile poison, has often been detected in partially burnt bodies and even in partially burnt bones. In two cases, also of homicide by strangulation, arsenic was detected in the viscera. Strychnine is a poison which is not often administered with criminal intent in India, but it is apparently a fairly frequent constituent of the nostrums prescribed by vaids and hakims, and a case is mentioned in the report in which two girls died as the result of medicine administered by an itinerant quack. Another case is brought to notice in which a woman was killed by a dose of nux vomica given in mistake for opium. Croton oil also figures in the list, but the sufferers recovered. It was apparently given with homicidal intent, and the drug was detected in the stomach wash and in some cooked pulse which had been partaken. The poisoning of cattle is a crime of frequent occurrence, and in the year under report the viscera of 111 animals were examined. Of these poison was detected in 63 cases, and arsenic was the agent in all but two. An interesting example

of accidental poisoning is cited, in which the death of two cattle was apparently traced to hydrocyanic acid in the fodder, and it is stated that other cases have been previously referred to the department in which young plants were found to contain hydrocyanic acid, probably owing to a cyanogenetic glucoside. In the present instance the plant incriminated was a species of sorghum.

Considerable advance has been made of recent years in the organisation and allocation of analytical work in India generally, and one excellent feature is the tendency to deal with public health details in separate laboratories. Bengal has now a public health laboratory, and the chemical examiner is therefore relieved of a whole department of analytical work which used to fall to his share. Another comparatively recent development is the establishment of a serological laboratory, which is now referred to frequently for blood examinations. During the year, in Bengal, 1876 articles were received for determination of blood, and of these 1018 were found by the imperial serologist to be stained with human, 3 with human and ruminant blood, and 43 with blood other than human. It is thus clear that the serological laboratory is being very freely used, and the findings of the serologist in criminal cases must often prove of great assistance to the police.

"THE LADY WITH A LAMP."

THE production of this play at the Garrick Theatre should be of great interest to the medical profession. Those to whom Mr. Lytton Strachey's essay upon Florence Nightingale, in "Eminent Victorians," is familiar will recognise how fully Mr. Reginald Berkeley, in writing the play, has followed Mr. Strachey's lead, a task which will have been rendered the easier to perform by the bibliography attached to that essay. The result is that we get on the stage a dramatic picture of a well-born and wealthy young woman, at the time when the social rules of her class were at their narrowest, determining that she had the right to follow the dictates of her highest self, and to defy all those rules, whatever pain and even humiliation such conduct might cause her family circle. In the play the mystical side of the influences which drove Florence Nightingale from the ball-room to the ward, and from marriage to the abnegation of all sex ties, is developed with great delicacy, while the hard-headed manner in which she carried out her gigantic policy of reform, when her emotional impulses had been transmuted into practical schemes, is also well displayed. There is, we assume, some historical justification for the suggestion that it was Palmerston's personal advice that induced Florence Nightingale, driven by her inmost conviction that her services would later be required, to train herself as a nurse, for in no other way could training be obtained. By sheer determination she acquired hospital experience and came to understand the principles of administration and sanitation as they were accepted 75 years ago. And by sheer intelligence she arrived at where those principles were wrong and where the principal needs of reform lay. Whether the author is accurately documented in the passages where Palmerston reveals, under his flippancy, a complete comprehension of Florence Nightingale's high purpose, and gave her the counsel that she needed, we do not know, but a fine dramatic situation is thus presented. The episodes in the play which have no historical derivation do not intrude on the central theme—the story of a task performed with a courage sparing neither of friends, of foes, or of self—and both the tragic love-story of the heroine, and the relations between her an and excusably jealous wife, are written finely and acted with the skill and distinction that were called for. If the main honours accrue to Miss Edith Evans, Miss Gwen Ffrangcon-Davies and Mr. Leslie Banks, who perhaps played more difficult parts, deserve high credit for their skilful impersonations, while Miss Muriel Aked, as Mrs. Nightingale, was delightful. The introduction of the word "antiseptics" at the period of the Crimean War is an anachronism.

STUDY OF HEREDITARY DISEASE.

THE association between blue sclerotics and a tendency to spontaneous fracture of bones was first recognised by J. Spierway some thirty years ago. He described a family of which four generations had had brittle bones, and observed that a feature common to many of its members was "a curious bluish tint of the eyeball." Working for the Nettleship Memorial Volume [1] on anomalies and diseases of the eye, Dr. Julia Bell has delved deeply into the literature, has discovered no less than 448 recorded cases of blue sclerotics, 200 in males and 248 in females, and has enlivened the subject with a keen perception of the less obvious corollaries of this curious association of abnormalities. Dr. Bell's ingenious comments have indeed put new life into dry bones. Few would look in a work on pedigree plates for such illuminating reflections on the apparent sex-incidence of hereditary diseases as are here supplied. In most of these there is, as is well known, a male preponderance; in fact, such diseases as hæmophilia and congenital dichromatism have given an impression that the male is peculiarly liable to be the victim of hereditary disease, and the female peculiarly potent as a transmitter. There is no known defect which affects only the female, but where as in most of the hereditary diseases males predominate, there seems to be a definite excess of female among the population affected with blue sclerotics. Achondroplasia and chronic trophedema are also exceptional in this respect, according to the pedigrees to which Dr. Bell has had access, but the numbers affected are too small to give any more than an approximation of the sex-incidence. Moreover, they may be misleading for other reasons. Sex-incidence of a disease, as Dr. Bell points out, is influenced by a great variety of factors differing from one disease to another, and any particular value may have little or no relation to the inherent relative liability of each sex to show the disease. The discussion of the sex-incidence of achondroplasia is an example of the complex factors which must be considered in an inquiry of this kind. The low value of the male sex-incidence of achondroplasia may be due to the fact that, the size of normal male heads at birth being anyhow larger than that of female heads, the exceptionally large heads of achondroplasic males lead to a selected infant mortality, with the result that a larger number of achondroplasic females survive birth. Possibly, on the other hand, there may be quite a different explanation—i.e., that, driven by obstetric difficulties, more adult females than adult males present themselves for treatment; this would lead to selection in the cases which come under observation. The values might be also affected in the other direction by such factors as concealment on the part of the female of a defect which might be regarded as a bar to marriage. But have we any evidence that the defect in the female is really a bar to marriage and that this factor does not operate for the male? A defective male might be expected to seek marriage in order to make sure of having somebody to look after him when disabled; moreover, a woman's maternal instincts might tend to draw her to mate with one who needed physical aid, and she might marry a disabled man in order to look after him.

In such intricate arguments do we become involved when the real meaning of an apparent difference in sex-incidence of hereditary defect has to be ascertained, and it may be readily imagined

[1] Eugenics Laboratory Memoirs, XXIV. The Treasury of Human Inheritance. Edited by Karl Pearson, F.R.S. Vol. II. Anomalies and Diseases of the Eye. Nettleship Memorial Volume, Part III. Blue Sclerotics and Fragility of Bone. By Julia Bell, M.A., M.R.C.P. 1928. London: Cambridge University Press. £1 16s.

hat only immense experience in evaluating tatistical data enables workers on such dangerous round to avoid pitfalls. This applies to any tatistical investigation, and it is becoming obvious hat while the collection of data may be entrusted to ny careful observer, they may need to be inter- preted with the help of those who, like Dr. Bell, re devoting their lives to such studies. In this onnexion, a book recently published by Dr. J. S. Manson [2] is of especial interest. This small volume onsists of a series of chapters, giving examples of pedigrees of hereditary disease in man, the major part of which have been already published elsewhere. The author, a busy practitioner, is to be congratulated on a valiant endeavour to add to the material avail- able for use by the student in heredity. All will agree with him that accurate and tabulated observa- tions of the progeny of human matings with distinctive characters should prove as valuable to the study of heredity as devised experiments on animals; this is after all the only real method in forming definite conclusions as to the working of genetic laws. The labour involved in the collection of information to form such pedigrees as those given for lamellar cataract and hereditary syndactylism and polydac- tylism must have been very great, and the value of such contributions to the collections of family histories on the subjects is undeniable. Having given this service, the author proceeds to a discussion of the material; such a discussion can only be of value if it is based on an analytical treatment of all available cases, of which he admittedly has no know- edge. Dr. Manson publishes one or two pedigrees of each of 14 different hereditary conditions. Those who have studied some hundreds of pedigrees of one condition hold that very little can be learned from a single pedigree, and that it is unwise to make any statement as to the hereditary character of any defect on such evidence. Moreover, an exhaustive knowledge of the literature of the subject is necessary before the general aspect of such complex phenomena can be understood. The fact remains that the data so carefully collected are of the utmost value. It is obvious that in medicine progress is retarded for lack of reliable statistics, and a prac- titioner who, like Dr. Manson, is willing to use his leisure in collecting such valuable material and pre- paring it for publication in readily accessible journals deserves hearty thanks. He spared himself no trouble in his endeavour to make his information of cases as complete as possible and has provided a number of very good plates, which admirably illus- trate the nature of the condition when this is possible.

LEPROSY IN MEXICO.

A VOLUME [3] of 501 pages contains the results of an attempt by the Government of Mexico to arrive at an estimate of the number of lepers within their borders. But unfortunately such an effort was fore- doomed to failure by the conditions which the compilers themselves describe.

According to the returns, only 1333 of the 2272 municipalities in Mexico have any resident medical men, and in addition there were no returns from 423 officials who should have given particulars of the doctors or hospitals in their areas. Of the 286 hospitals and medical institutions to which circulars were addressed not two-thirds sent answers, and replies were received from only just over half the 2756 doctors to whom application was made. It is necessary to insist on these figures because only thus is it possible to realise that the volume has no value for purely scientific purposes; it is impossible to make any trustworthy deduction from a census which on the compilers' own showing covers less than seven million out of 15 million inhabitants (p. 499). The figures given no doubt have a certain value for administrative purposes; they indicate to some extent the magnitude of the evil with which the authorities have to grapple, and show some of the principal foci of the disease in the areas covered. But it is unfortunate that the editors should have treated them as if they were complete and made a map which, while purporting to show the relative distribution of leprosy in the various provinces, can only mislead those who are not acquainted with the facts. In the province of Oaxaca, for instance, only 8 per cent. of the population are even supposed to be covered by the inquiry, and it is stated (p. 277) that the actual conditions do not allow of an inquiry of this character; yet this province is entered on the map as having from 1 to 50 cases of leprosy. It may be said in conclusion that the figures, for what they are worth, show 1450 lepers in the areas covered by inquiry, of whom 734 showed the nodular form, 262 the nervous, and 283 the mixed, whilst in the rest the form was unknown. Only 27 of the lepers were foreigners, 15 being Asiatic. The statistics have been carefully analysed and perhaps the most important practical point is that lepers were found in every profession and occupation, an evil which stricter enforcement of existing laws could apparently stop. Leprosy is clearly endemic in Mexico to a considerable extent, doubtless much greater than is here indicated, and the census report, though it does not deal with measures of prophylaxis, is a satis- factory indication that the authorities are alive to the urgency of the problem.

HERPES AND VARICELLA.

EVERYONE who tries to find out what has been written on the relation of herpes zoster to chicken-pox will agree with Dr. A. Wallgren [1] that the literature needs pruning. But his own contribution, comprising some personal observations together with a review of recent Scandinavian papers, is a sound outgrowth from this large tree, and his dozen cases are scrupulously recorded. They formed a little epidemic of herpes and varicella in a children's ward at Göteborg, and he regards them as undoubtedly showing an ætiological bond between the two diseases. This relationship may be twofold: first, herpes zoster may be identical with chicken-pox; and, secondly, one may provoke the other or predispose to it, just as measles is said to predispose to whooping-cough. Very interesting are Wallgren's notes on the power of visceral and glandular tuberculous lesions to provoke a herpetic lesion at a corresponding segmental level—an occurrence of which he gives characteristically minute records. In calling for more information on the association of herpes and other diseases he urges the necessity for strict and conclusive investigations concerning incuba- tion periods and absence of previous attacks. Some accounts of their coincidence, as he says, do not ring true, and there are both clinical and experimental observations opposing any relationship. He fairly quotes the quaint remark of Comby, after some of this latter work, that chicken-pox can no more be produced by herpes zoster than a chicken can be born from a duck's egg. Incidentally, whilst stating that studies on the subject go back 37 years to von Bokay, he does not mention that it was A. J. Harrison, President of the Dermatological Society of London in 1900, who urged that certain cases of herpes zoster are manifestations of acute specific infectious exanthemata.

A COPIED PRESCRIPTION.

A VERDICT of death by misadventure was recorded a few days ago by the Hammersmith coroner at the inquest on a man who died in a London nursing home from an overdose of paraldehyde given as a pre- liminary to an operation, the error being due to the faulty copying of a prescription. The patient was a man 44 years of age who had taken the same

[1] Acta Pæd. Scand., 1928, viii., 241.

anæsthetic previously for severe dental extraction and was well pleased with the result. The intention of the anæsthetist was to administer by the rectum 9 drachms of paraldehyde—that is to say, the customary 1 drachm per stone of body-weight—in 5 ounces of olive oil, and in accordance with the practice at the nursing home his prescription was copied by a nurse before being sent to the pharmacist. The instruction, as the latter received it, was to send 9 ounces of paraldehyde and 5 ounces of olive oil, and there was nothing on the copied prescription to indicate that these were to be given in combination as a single dose. Paraldehyde, as the pharmacist stated in his deposition, is not scheduled as a poison or as a dangerous drug. He was at liberty to sell it in large quantities to anyone, and may readily have believed that the prescription was intended for stock. It is reasonably clear, however, that the mistake would not have occurred if the original prescription as written by the anæsthetist had actually reached the dispenser who was a qualified chemist and druggist. Even should there have been any doubt as to whether the Arabic sign was intended to represent a drachm or an ounce, the dispenser must have realised that he was being asked for a single narcotic dose prescribed for a particular patient, and his knowledge would then have prevented him from supplying a quantity of paraldehyde which he would recognise as being highly unusual if not actually dangerous. The lesson of the tragedy seems to be not so much the difficulty of deciphering doctors' prescriptions—in this case we have every reason to believe that the prescription was correct and clearly written—as the avoidance of introducing an element of risk by interposing a third party between the doctor's wish and its execution by the pharmacist. Both the doctor and the patient are well served by the pharmacist's experience in interpreting prescriptions, and no prescriber would be willing to forgo the safeguard of the dispenser's expert and often critical eye. In this case no individual seems to have been to blame. The disaster was the outcome of a long-standing tradition in a nursing home, which, however inadvisable, had not previously led to any doubt or difficulty. It is, however, just as well that this aspect of the lesson should be enforced in order that nothing of a similar nature should recur.

THE BRITISH SOCIAL HYGIENE COUNCIL.

WHEN the Local Government Bill becomes law the British Social Hygiene Council will be faced with the loss of its Government grant. By a clause passed this week official donations to this body are to be a matter for the local authority to determine, although the Ministry will give every encouragement to county and borough councils to subscribe. An amendment to make the grant compulsory failed to secure the support of the Minister or the approval of the House. It was strongly supported by Dr. F. E. Fremantle, who did not agree with the Parliamentary Secretary to the Ministry of Health that this propaganda work could now be undertaken by the local authority, and who quoted figures to show that only very small sums are at present allocated by these bodies to the prevention and control of venereal disease. He was of opinion that they were, in fact, entirely dependent upon the Council and its organisation in any work they undertook, and that the problem had not yet really got down to the individual conscience of the population. He feared that without the prestige and practical assistance of a Government grant the movement would fade away, and he reminded members of the pioneer work of the Council in the early days of its foundation—as the result of the recommendation of a Royal Commission. At that time venereal disease could not be named in the press, in the House, or in the reports of medical officers of health, and there was no machinery for dealing with the problem. The Minister of Health cordially agreed that the work of the Council had been invaluable, but maintained that local authorities to-day were alive to the importance of venereal disease propaganda, and that they must be left free to approve the activities they would support. The only comfort he could give the friends of the Council was a promise that he would urge on local authorities the importance of financing a central body, and an assurance that he personally hoped for the continued and increasing activity of the Council. Only experience can show whether or not he is justified in his belief that the Social Hygiene Council will be able to continue its valuable work under the new conditions. All who know its history and progress will hope that it may. Under enlightened guidance the Council early realised that the problem of venereal disease was not to be solved by direct attack or negative means, but that a campaign of education and stimulation of the moral conscience of the Empire was the only fruitful procedure. The thirteenth annual report, recently published, tells the story of widespread activities, including every part of the dominions. Health weeks and lectures of all kinds are organised, conferences are arranged, and work is carried out in connexion with other national societies. The diminution in the incidence of syphilis does not, therefore, constitute any argument for curtailing the work of the Council, and even in the more limited field of venereal disease there is urgent need, as the report points out, for more facilities for diagnosing and treating antenatal cases and for the in-patient treatment of gonorrhœa. Biological education is of particular value in relation to sex conduct, and instruction in social hygiene is a work that no civilised community can afford to neglect.

PREVENTION OF HAY-FEVER.

IN a Statistical Report on the Treatment of Hay-Fever, Dr. M. A. Ramirez,[1] of New York, describes a study of 425 cases of this condition treated by injection of pollen extracts. He prefers to call hay-fever "pollen rhinitis," and begins his paper with a brief description of the scratch and intradermal methods for the diagnosis and detection of the pollen responsible. The best results in treatment, he says, were got when patients came about three months before the expected paroxysm. In these a fortnight's intensive course of injections of the appropriate pollen extract was given at once. The dosage was rapidly increased and injections continued up to the pollen season, during which they were given twice weekly. This form of prophylaxis was supplemented by administration of autogenous vaccines prepared from the nose and by nasal application of solutions of pollen extract. In addition, local treatment of the nose with the Kromeyer lamp was often found advantageous. Neither autogenous vaccines, nor local application of pollen solution were found of any value by themselves, though they were helpful in cases being treated by injection. Ramirez urges that the largest possible doses of pollen extract should be given for several months before the pollination season and that massive doses should be continued until it is over.

Dr. Francis de Havilland Hall, who died of pneumonia, after a week's illness, at Twickenham on Sunday last, in his eighty-second year, was consulting physician to the Westminster Hospital, and had examined in medicine for the Royal College of Physicians of London and the University of Durham.

A FORTNIGHT ago we commented in these columns on the attention drawn by the Ministry of Agriculture and Fisheries to the growing demand existing throughout the British Empire for men trained in biology. This matter is at present being debated by a joint committee at the Universities Bureau of the British Empire, where the discussion takes the form of examining into the practical steps which might secure the development of the teaching of biology by cöoperation between the universities and secondary schools.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XX.—THE SIGNIFICANCE OF OCULAR TESTS.

PART I.—MONOCULAR TESTS.[1]

VISUAL tests fall into two groups: (1) monocular, (2) binocular.

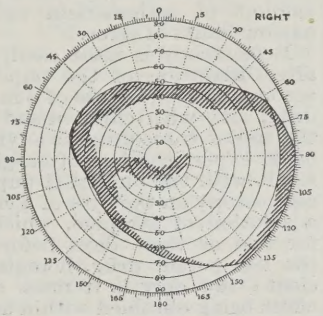
Monocular tests are carried out on each eye separately, the other being screened off. In considering tests for visual acuity it must be remembered that the central fixation point, an extremely circumscribed area of the retina, is endowed with acute perceptive power, and that immediately outside this area retinal perception falls away steeply towards the periphery. So great is this difference that entirely different tests are used for central and peripheral acuity of vision.

Snellen's types.—The standardised test for central acuity of distance vision consists of the familiar Snellen's types, a series of black letters of diminishing sizes arranged on a white ground, and placed at a uniform distance of 6 metres from the patient. Each row of letters from above downwards is of a size which should be readable at a certain definite distance, the large letter at the top at 60 metres, the second row at 36 metres, the fifth row at 12 metres, the seventh at 6 metres, this last being the normal standard. Acuity is expressed by a fraction, the numerator indicating the distance from the types, and the denominator the distance at which a person of normal acuity should be able to read letters of the smallest size which the patient can read.

Diagrams of Pathological Visual Fields.

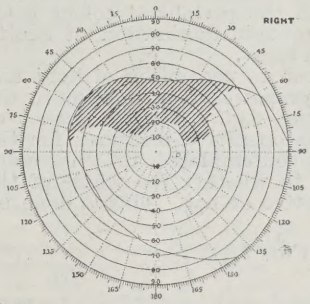
In each case the shaded part represents the blind area.

FIG. 1.



Right field from a case of chronic glaucoma showing a paracentral scotoma joining with a blind area in the nasal field. The field is contracted peripherally.

FIG. 2.



Field from a case of detachment of the lower part of the retina in the right eye.

Normal vision is expressed as 6/6—that is, the patient can read at 6 metres what he ought to read at that distance. If he can read only the top letter his vision is 6/60; if the second row, 6/36; and if the fifth, 6/12. 6/6 vision is merely an average standard of good acuity, and most normal eyes can read even smaller letters at 6 metres distance, the acuity being 6/5 or even 6/4.

Obviously, unless care is taken to correct any existing refractive error which interferes with vision by a suitable lens, this test does not show the actual efficiency of the eye.

Jaeger's types.—For testing acuity of near vision, Jaeger's types, which are ordinary printers' types of different sizes, are commonly used. The distance from the eye at which the type is held, as well as the actual size which can be read, must be taken into account. Myopes will hold the type close to the eyes, and the higher degree of myopia the nearer will it be held. Normal-sighted persons and hypermetropes who have reached middle age will, on the contrary, tend to hold the type far away, the distance increasing as age and its attendant presbyopia advance. A tendency to hold the book close to the eyes is not, however, invariably due to the presence of a myopic error. It is commonly met with in children, especially those to whom reading does not yet come easy, and is due to an instinctive effort to see the type as clearly as possible; the nearer the book is held the larger is the image of the type formed on the retina, and because the accommodative power of the eye decreases as age advances, and is much greater in childhood than in adult life, the young eye can focus objects at a closer range than is possible later on in life. In prescribing glasses the question of normal reading distance is of great importance; only a correction which will ensure this can be worn with comfort.

Perimetry.

The measurement of visual acuity in the peripheral field outside the central fixation point is known as perimetry, and is carried out by determining the power of perception of movable objects of graduated sizes in various parts of this field, while the patient directs his gaze steadily towards a fixed point. For this purpose many different devices and instruments are used, but in all of them there must be a fixed central object and a rest, or appliance, for keeping the head in a steady position during the examination.

The test objects consist of white and coloured squares or discs of various sizes. A perimeter is an instrument consisting of a fixed upright to which is attached a movable curved arm, the latter forming the arc of a circle along which the tests object may be moved, either mechanically or by hand, so that the area tested may be measured and recorded on a chart marked in degrees radially and concentrically, with the fixation point as centre. Alternatively the field of vision may be tested on a flat screen (Bjerrum's screen), the test objects being mounted on holders, and moved about at will.

The Interpretation of Blind Areas.

The interpretation both of blind areas (scotomata) and of areas of lowered sensibility in the field of vision is of very great importance in the diagnosis of lesions in the nerve path of visual impressions. The characteristic changes which occur throw light both on the position and nature of such lesions, whether in the nervous elements of the eye itself or in the path to the visual cortex. Chronic glaucoma is an outstanding example of nerve derangement in the eye itself, in which the field changes are all important in early diagnosis. In this condition abnormal pressure on the optic nerve-fibres at their point of exit from the eye causes them to atrophy, and their destruction is selective in the early stages of the disease as regards different parts of nerve. This selective destruction shows itself in the field of vision as blind areas; these correspond to the distribution of the atrophied fibres, and usually appear first in the neighbourhood of the blind spot and in the nasal field (Fig. 1), while preservation of central vision is possible in association with considerable paracentral and peripheral loss of field.

In cases of localised detachment of the retina perception is lost, or greatly diminished, over the area of the detachment, which becomes manifest as a blind area in the field of vision (Fig. 2); this is an extremely valuable adjunct in the detection of small peripheral

[1] Part II., on Binocular Tests, will appear in THE LANCET next week.

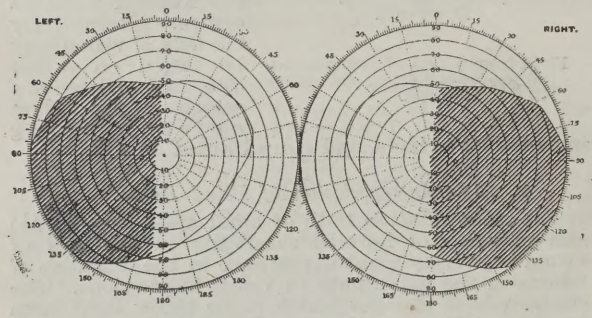
detachments, and in the measurement of increase or decrease in the area of a detachment.

Hemianopia.

Again, the relative arrangement of the nerve-fibres in the paths conveying visual impressions to the cerebral cortex corresponds with that of the retinal surface, and this arrangement is also reproduced in the visual cortex itself. Also the nasal half of one retina and the temporal half of the other is represented in each hemisphere and in each optic tract, for which reason blindness involving half of each visual field (hemianopia) is a common accompaniment of lesions affecting these structures. The hemianopia involving the temporal half of each field (bitemporal hemianopia, Fig. 3), caused by pressure of a pituitary tumour on the inner parts of the optic tracts in the neighbourhood of the chiasma, and the hemianopia involving corresponding temporal and nasal halves of each field (homonymous hemianopia, Fig. 4) which arises from destruction of the occipital cortex of one hemisphere, will serve to illustrate this. Normally the extent of the peripheral field over which colours can be perceived is different for each colour, and pathological disturbances in colour perception, whether central or peripheral, are of great significance. For example, in cases of tobacco blindness central perception of red and green is diminished early in the disease and abolished in the later stages; also in cases of retrobulbar neuritis central perception of red and green is lost. With the hemianopias of pituitary enlargement changes in the peripheral colour fields accompany and may precede diminution of acuity for white in the affected areas.

When vision is reduced to perception of light and shadow, owing to the presence of an opacity in the anterior part of the eye—e.g., a dense cataract or closed pupil—and when operative measures for the restoration of sight are contemplated, it is necessary to form an opinion as to whether the whole of the retina is likely to be active or not. This is done by

FIG. 3.



Fields from a case of pituitary tumour, showing bitemporal hemianopia.

directing light upon the eye by means of a reflecting mirror from all directions in turn. If the retina be normal the patient will be able to "project" the light to its source—in other words, will point quickly and accurately to the mirror in each separate position.

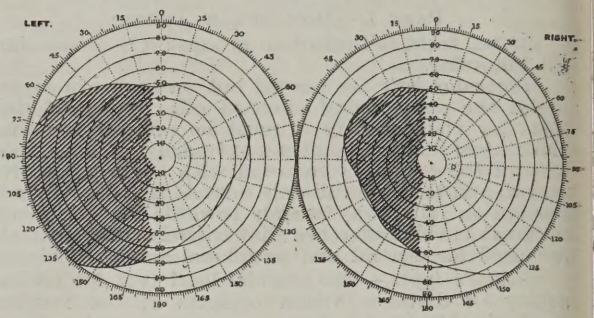
Measurement of Refraction.

The basic test for measurement of refraction is retinoscopy (or skiascopy), which is purely an objective one. It is performed by throwing light into the patient's eye by means of a mirror so that the light is reflected back from his fundus, making the pupil appear luminous to the observer. The mirror is then tilted slowly so that its reflected light gradually moves off the patient's pupil, the direction of this movement being meanwhile observed.

In emmetropic and hypermetropic eyes the rays of light emerging from the pupil of the eye under observation are parallel and divergent respectively, are reflected directly from the fundus, and will move off the pupil in the opposite direction to that seen in myopic eyes, in which the rays of the emergent beam cross and form a real image before meeting the observer's eye, this real image taking the place of the fundus as the source of light.

By determining the strength of lens necessary to obtain reversal of the direction of movement in each

FIG. 4.



Fields from a case of tertiary syphilis, showing homonymous hemianopia, the result of pressure from a gumma on the right occipital cortex.

case, the refraction of the eye and the existence and amount of astigmatism can be estimated within narrow limits of error.

Retinoscopy is most easily and quickly performed after dilatation of the pupil and inhibition of the accommodation by use of a mydriatic and cycloplegic drug, and with children and young adults especially the use of these drugs is advisable; but in the hands of an expert the test often gives an equally accurate result with the undilated pupil. Before performing a retinoscopy on the eyes of a child it is usual to employ a solution of atropine, which is instilled twice daily for two or three days beforehand, but in an adult the less potent drug, homatropine, is generally sufficient; not only is it more rapid in action, the full effect being obtained within an hour after instillation, but its time of action is much less prolonged than is the case with atropine.

The indiscriminate use of mydriatics in middle-aged and elderly people is extremely dangerous, owing to the possibility of determining the onset of an attack of acute glaucoma in a predisposed person by dilatation of the pupil. For this reason careful examination of the eye must always be made, special attention being paid to the depth of the anterior chamber before any mydriatic drug is instilled.

The test is followed by a subjective one, based upon the objective findings, Snellen's types being used; other subjective tests may also be employed—for example, charts showing radiating lines (astigmatic fans) may be used as aids in the determination of the axis of astigmatism. An ingenious application of the difference in wave-lengths of colours at opposite ends of the spectrum has recently been devised. This "Duochrome" test consists of two strips of letters, each on an illuminated transparent ground, one red and one blue. The short hypermetropic eye sees the blue more clearly, and the long myopic eye the red, and the test is carried out by equalising the clearness of the colours with lenses of appropriate strength.

R. AFFLECK GREEVES, F.R.C.S. Eng.,
Surgeon to Moorfields Eye Hospital; Ophthalmic Surgeon to the Middlesex Hospital.

HOSPITALS AND STREET ACCIDENTS.—In his first annual report Dr. J. N. Deacon, medical superintendent of the Hendon Board of Guardians' Hospital at Redhill, Edgware, states that of 313 urgent admissions for treatment of injuries 270 were the result of street accidents. These 270 cases "cost the ratepayers of the Hendon Union something in the region of £4000."

MEDICAL EDUCATION OF WOMEN UNDERGRADUATES.

REPORT OF THE UNIVERSITY OF LONDON COMMITTEE.

A COMMITTEE of the University of London was constituted on March 21st, 1928, to consider the question of the limitations placed upon the medical education of women undergraduates and to report to the Senate thereon. Its members were Sir William Beveridge (then Vice-Chancellor), Prof. S. L. Loney (chairman of Convocation), Prof. L. N. G. Filon, F.R.S. (chairman of the Academic Council), Dr. Graham Little (chairman of the Council for External Students), Sir Holburt Waring (chairman of the Finance Committee), Dr. W. P. Halliday (principal of King's College), Dr. W. R. Matthews (Dean of King's College), Mr. Walter Spencer, Miss E. Strudwick (principal of St. Paul's School for Girls), Sir Andrew Taylor (chairman of the Managing Committee, University College), and Miss M. Tuke (principal of Bedford College for Women). Sir William Beveridge acted as chairman. The committee had 11 meetings, on March 23rd, May 4th, 14th, 18th, and 21st, June 7th, 15th, and 26th, Dec. 19th, 1928, and Jan. 15th and 23rd, 1929. At the request of the committee the meetings were attended by the Academic Registrar, who prepared a statement and furnished statistics for their information. At some of these meetings representatives of certain of the medical schools and others interested in the question were interviewed, including the Women's Medical Federation, and the Vice-Chancellor convened a meeting of representatives of all the medical schools, which was also attended by the Chairman and the Academic Registrar. The committee express appreciation of the assistance given in the inquiry by the medical schools. It was thought desirable that they should express their views in the frankest possible manner, and an undertaking was therefore given that their statements of opinion would not be published. Certain statistical information furnished by the schools is also unpublished, but in an appendix other statistical material is set out which had a bearing on the conclusions arrived at.

A number of communications and resolutions were received from Convocation and from various other bodies, including the following: the Six Point Group, the National Council of Women of Great Britain, the Council of the League of the Church Militant, the Women's Freedom League, the Executive Committee of the Association of Head Mistresses, the Women's League of New South Wales, the Women in the Service of Hospitals Joint Committee.

After setting out this general information the committee proceeded to report as follows:—

MEDICAL CURRICULUM.

It is perhaps desirable that we should state in the first instance the nature of the medical curriculum.

The course leading to the first degree in Medicine (M.B., B.S.) extends over a period of five and a half to six years, of which approximately half is devoted to pre-clinical and half to clinical studies.

The pre-clinical studies are divided into stages. The first ends with the First Medical Examination and comprises physics, chemistry, and biology. This examination is taken by a number of students at school before coming to the University; the Intermediate B.Sc. Examination is also taken by a considerable number of students (principally at University and King's Colleges) in lieu of the First Medical Examination. The second stage of the pre-clinical studies leads to the Second Medical Examination, which itself has two sections; Part I. comprises Organic Chemistry, and Part II. Anatomy, Physiology, and Pharmacology.

After a student has passed his pre-clinical examination, he enters a hospital medical school for his clinical courses which include medicine, surgery, midwifery, pathology, and the various "specialties." After the conclusion of the three-year clinical course the student proceeds to the M.B., B.S. Examination. It may be noted here that the clinical courses provided at most of the London hospital medical schools are designed to cover the needs of three types of students: (1) students working for degrees of the University of London; (2) students from other universities who come to London for clinical studies leading to degrees of those universities; and (3) students preparing for diplomas, such as those of the Conjoint Board (M.R.C.S., L.R.C.P.). The clinical courses for these three types of students are substantially the same.

COLLEGES AND SCHOOLS PROVIDING MEDICAL COURSES.

The following colleges and schools provide courses, pre-clinical, clinical, or both:—

Incorporated Colleges of the University.—University College and King's College provide complete pre-clinical courses.

Schools of the University.—(*a*) *General Schools.*—East London College provides courses for the Intermediate B.Sc. Examination.

(*b*) *Medical Schools.*—Complete courses are provided at St. Bartholomew's Hospital Medical College, St. Thomas's Hospital Medical School, Guy's Hospital Medical School, London Hospital Medical College (first pre-clinical course taken at East London College), Middlesex Hospital Medical School, London (R.F.H.) School of Medicine for Women, and St. Mary's Hospital Medical School. Clinical courses only are provided at Westminster Hospital Medical School, St. George's Hospital Medical School, Charing Cross Hospital Medical School, University College Hospital Medical School, and King's College Hospital Medical School.

Prior to the war all the medical schools, with the exception of the London School of Medicine for Women, which was founded for women only, were restricted to men, but during the war this policy was modified in several cases.

In 1916 *St. Mary's Hospital Medical School* undertook to receive for clinical studies women from the London School of Medicine for Women only. In the same year *Charing Cross Hospital Medical School* admitted women "on the same terms as men," and *St. George's Hospital Medical School* agreed to admit women up to the number of ten during the continuance of the war.

In 1917 *Westminster Hospital Medical School* admitted women, but it does not appear that this decision was formally communicated to the Senate.

In May, 1918, the *London Hospital Medical College* informed the Senate of their intention to admit women on the same terms as men. The Senate then stated that the step was "in entire conformity both with the wishes and the policy of the University."

In June, 1918, *King's College Hospital Medical School* resolved to admit women and the Senate made a similar pronouncement.

In July, 1918, *University College Hospital Medical School* decided, in the event of the Senate approving certain arrangements with other institutions, to receive women, and the Senate, when agreeing to these arrangements, stated that they "learnt with gratification of their proposals."

By July, 1918, then, clinical facilities were available for women at seven of the medical schools in addition to the London School of Medicine for Women. Four of the men's schools, St. Bartholomew's, Guy's, St. Thomas's, and Middlesex, had made no change in their traditional policy. At this date, of the 12 medical schools providing clinical courses in London four were confined to men, one was confined to women, and seven were open to both sexes. The relative extent of medical co-education was less than these figures would suggest in so far as the co-educational schools were generally smaller than the others.

After the war the position began to alter.

St. George's Hospital Medical School ceased in 1919 to admit any more women, although the Senate does not appear to have been officially informed. In November, 1921, the authorities of the *London Hospital Medical College* stated (S.M. 1189 of December, 1921) that they had "formed the opinion that the interests of both institutions (College and Hospital) are adversely affected by the continuance of co-education, and have therefore decided to limit admission to men students only in the future." In 1924 *St. Mary's Hospital Medical School* decided to admit no more women students; here also the Senate does not appear to have been informed. Nor has the Senate been informed, although it is a matter of common knowledge, of the decision taken in

1928 by Charing Cross, Westminster, and King's College Hospital Medical Schools to discontinue the admission of women students in the future.

The effect of this change of policy is that there are at the present time two schools only which offer clinical facilities to women—the London School of Medicine for Women, and University College Hospital Medical School, which, since 1921, has admitted 12 women a year—eight on the nomination of University College, and four by examination.

It may be pointed out that it is the withdrawal of facilities for *clinical* instruction only which has given rise to the present inquiry. The facilities for *pre-clinical* instruction for women are ample. There has been no change of policy regarding the admission of women to University College and King's College for pre-clinical courses, and these Colleges with East London College (which are all co-educational) could continue to provide for the needs of such women as are likely to present themselves for some years. The fact, however, that there may be difficulty in finding clinical facilities subsequently must inevitably affect the number of entrants for pre-clinical courses.

PREVIOUS INQUIRIES.

During the war the Academic Council, who were anxious regarding the adequacy of clinical facilities for Women, appointed (in December 1915) a subcommittee with the following terms of reference :—

"To consider the present provision of facilities for the medical education of women in London; whether these facilities are adequate; and if not adequate, what means should be adopted with a view to extending them."

The subcommittee held 12 meetings and interviewed 28 witnesses, including the deans of the medical schools. The report of the subcommittee dealt at some length with the general question of co-education for women, including the opening of the Anatomical Departments of University and King's Colleges to women. On the general question the subcommittee states (paras. 13 and 15) :—

"It has been urged that medical women cannot acquire the necessary self-confidence and responsibility unless they see in their daily work other women occupying responsible positions on the same terms as men; and looking at the question from another point of view, it has been pointed out that if all the medical schools in London were opened to men and women alike the number of women students in most of them would be insufficient to provide the students with that social and corporate life which is an essential part of University education.

"We are of opinion that no valid objection can be maintained against the system of co-education for men and women medical students; and that this is the only system by which the general policy of the University can be effectively carried out. In our opinion adequate facilities for the medical education of women would not be provided in any hospital or medical school unless resident medical and surgical appointments were open to men and women on equal terms."

The report was forwarded by the Academic Council to the Senate, who resolved to communicate it to the schools in the Faculty of Medicine and to inform them that the Senate would be prepared to arrange for a conference and authorised the Academic Council to hold such a conference.

A conference was held on Jan. 30th, 1917, under the presidency of the then Vice-Chancellor (Sir Alfred Pearce Gould). The proceedings are set out in Appendix Ac. A. to the Senate Minutes of July, 1917. There was considerable divergence of view among the representatives attending. The Senate, after receiving the report, resolved that for the present no further action be taken in the matter. Owing to the action of the various medical schools in admitting women (see above) the question had solved itself, at least for the time being.

Again in 1921, on being notified of the decision of the London Hospital Medical College (see above) the Academic Council appointed a subcommittee to consider the question of the adequacy of clinical facilities for women. The report of that subcommittee, which was adopted by the Academic Council, is set out in S.M. 1339 of January 1923. They were of opinion that at that time there was no lack of clinical facilities and that it was not advisable to take any further action.

The Problem.

The problem before us has two aspects—that of providing clinical facilities adequate for the number of women requiring them, and that of providing such facilities in schools open to both sexes.

In its first aspect the problem is a comparatively simple one. The great increase during the war in the number of women taking up medical studies has been followed since the war by a striking decrease.

If we look at Part II. of the Second Medical Examination (see Table III.) as marking the passage from pre-clinical to clinical studies, we see in 1918 the number of women in London substantially exceeding that of the men; in 1919 the numbers are practically equal; from 1920, while men have maintained or increased their numbers, the women have fallen to less than one-half. In the London School of Medicine for Women the total number of students from 193 just before the war rose to 459 in 1920–21 and fell to 298 in 1926–27. Outside London the fall of women medical students, as appears from Table IV., has been even more marked.

TABLE I.

The following information, kindly supplied by the Registrar of the General Medical Council, shows the number of men and women whose names have been placed upon the Medical Register during the years mentioned :—

—	Men.	Women.	Total.	—	Men.	Women.	Total.
1922 ..	1657	475	2132	1925..	2245	490	2735
1923 ..	1999	514	2513	1926..	1797	376	2173
1924 ..	2341	474	2815	1927..	1649	319	1968

TABLE II.

The following figures (reports of University Grants Committee) show the numbers of full-time women students at the London School of Medicine for Women in the years mentioned :—

Year.	Medical	Dental	Total	Year.	Medical	Dental	Total
1920–21	447	12	459	1924–25	344	1	345
1921–22	433	11	444	1925–26	315	—	315
1922–23	409	10	419	1926–27	297	1	298
1923–24	374	2	376				

TABLE III.

This table, extracted from the University Calendar, shows the numbers of candidates at University examinations in medicine since 1916 (M., men; W., women) :—

Year.	First Medical.		Second Medical I.		Second Medical II.		M.B., B.S.	
	M.	W.	M.	W.	M.	W.	M.	W.
1916 ..	190	157	125	88	146	57	42	22
1917 ..	181	213	113	148	109	77	54	27
1918 ..	252	244	150	182	117	159	79	47
1919 ..	477	236	256	222	201	200	140	40
1920 ..	628	251	444	197	301	237	242	45
1921 ..	441	230	355	168	383	157	186	114
1922 ..	460	188	290	170	471	192	190	124
1923 ..	427	103	325	149	325	180	199	182
1924 ..	359	80	343	91	318	162	303	196
1925 ..	420	84	303	67	313	110	370	227
1926 ..	378	71	292	76	306	87	382	225
1927 ..	391	73	310	62	328	103	270	150

It would, however, be unwise to assume that the figures of women entrants will remain at their present low level. There appear to be already indications of a revival, and, though the policy of exclusion may for a time result in a number of women seeking admission to medical schools in the provinces and elsewhere, they will not, and in our view they should not, consent to being excluded from participation in medical education in the Metropolis. Taking all things into consideration, we are of opinion that the provision of 100 clinical places for women, apart from those

available at the London School of Medicine for Women, would be ample for the next few years. The London School of Medicine could during the war take more students than it has at present, and we understand that for the next year or two it could admit 15 more clinical students each year.

TABLE IV.

The following figures (reports of University Grants Committee) show the number of full-time students in (*a*) Great Britain, (*b*) London institutions, in the Faculty of Medicine in the years mentioned :—

Year.	Great Britain.		London.*	
	Men.	Women.	Men.	Women.
1920–21	8896†	2741†	2621	1040
1921–22	9017†	2595†	2873	1070
1922–23	9498	2368	3026	1049
1923–24	8866‡	1998‡	3048‡	936‡
1924–25	7896‡	1631‡	2894‡	823‡
1925–26	7288	1402	2840	775
1926–27	7179	1236	2713	683

* Excluding Guy's Hospital Medical School.
† Excluding universities of Oxford and Cambridge.
‡ Excluding St. George's and Westminster Hospital Medical Schools.

The numerical side of the problem, however, is the least important one. The real issue is as to the maintenance in London on a substantial scale of facilities for medical co-education at the clinical stage. This is a question of broad principle which different persons will approach with different prepossessions.

In all its other large faculties—e.g., in Arts, Science, Economics, Laws—the University of London is predominantly co-educational; actually, though it has a few Colleges confined to women, it has none in these faculties confined to men. The prepossession of the University of London has on more than one occasion been expressed to be in favour of a measure of co-education also in the great Faculty of Medicine. Is there any feature peculiar to medical studies making co-education, which predominates in the rest of the University, undesirable in that one field ?

CO-EDUCATION IN MEDICINE.

We can say at once that we are satisfied that the relationship existing between men and women students of medicine is not of itself an objection to co-education, and we are glad to say that none of the representatives of schools who had had actual experience of women students alleged any case of difficulty or the need of disciplinary action arising out of this relation; uniformly the conduct of the women was described as excellent. In this respect our own conclusions agree with those arrived at by the inspector appointed by the Senate, the late Dr. J. George Adami, in his report on the medical schools (S.M. 2435 of March 26th, 1924). The report stated :—

"The reports of the Deans of the co-education schools regarding the work and attitude of the women students were uniformly favourable. The Dean of one school bore evidence to the improved tone of the men students since women were admitted. The Deans of two schools gave it as their impression that as the result of co-education the women students of their schools were more womanly and more considerate in their dealings with hospital patients than women trained apart from men."

Other objections have been urged: the necessity of providing special accommodation (residential and other) for a mixed staff; the difficulties of teaching mixed classes in some subjects; the tendency of women to crowd to the front at demonstrations; and the difficulty in the way of reproving a person of one sex in the presence of persons of the opposite sex. We think there may be some force in these objections, but here also they have not been felt to be insuperable by schools with actual experience of co-education, and in fact they appear to us capable of adjustment with no more difficulty than most co-educational problems.

Nor are we impressed by the argument that the medical education of women is to a great extent thrown away by the "wastage" that occurs owing to marriage and other reasons which result in women leaving the medical profession after undergoing the expense and difficulty of qualification. As a matter of fact, it would appear from the information before us that the "wastage" is much less considerable than is sometimes supposed. In so far as it has any weight, the argument tells not against co-education in medicine, but against any medical education of women at all. In London it certainly cannot be used as an argument for curtailing the facilities for women, for, in the aggregate, the number of places vacant is certainly greater than the number of applicants who could fill them. On the other hand, we think it is clear that in medicine women certainly gain by being educated side by side with men, and that such an education is a very valuable training for that coöperation which in their subsequent careers becomes necessary between medical men and women. It may be that the advantage is not felt so much by men students, and indeed co-education for some men may not be profitable. On the balance, however, we think that the advantage to the women outweighs any possible loss to the men.

We do not suggest, however, that there are no difficulties in the way of medical co-education in London. They are not the difficulties we have already referred to. The real difficulties arise from (*a*) the multiplicity of medical schools and their competition for students, and (*b*) the feeling against co-education entertained by some of the men already in the medical profession, some of the men students, and a section of the public. With few exceptions the authorities of the medical schools appear to be convinced that men, if they have a choice, prefer to go to schools which do not admit women, and that the feeling is strongest among the men, and in some cases the parents of the men, who on general grounds would be most desirable. Since there are now certainly not enough students to fill all the schools, this means if some schools admit while others exclude women, that co-education is in unstable equilibrium; and that the school which admits any women will have a disappearing number of men. This feeling of antipathy may be deplored, but we have no doubt as to its existence, and since the medical schools are dependent to a very considerable extent on the income derived from students' fees, it is only natural that the authorities of the schools should be concerned with the economic problem to which it gives rise. In one of the cases at least in which a genuine attempt was made to provide absolutely fair treatment to women students, it was only the apprehension that the policy of co-education was heading the school for disaster which led to its reversal. How the exclusion of women can in all cases increase the number of men entrants all round is not obvious, for the number of possible entrants is not unlimited; that, however, is a matter on which we need not express an opinion. How long this feeling is likely to endure, and, in particular, whether it would endure indefinitely against the attraction of first-rate teaching and equipment in a co-educational school, are questions which it is difficult to answer.

Conclusions.

We are unable to see any valid argument on the merits against the provision of co-education in medicine. The prepossession of the University is in favour of such co-education. The changed public position of women and the general development of the relations between men and women in the past generation are too obvious to need comment. If the field were clear we find it hard to believe that anyone who at the present day was planning fresh medical education in London as a whole would plan it otherwise than on the basis of being, like education in the other faculties, predominantly co-educational. In medicine, as in other fields of study, the services of the schools of the highest prestige and the teachers

of the highest distinction should be available to men and women indifferently, and men and women, who after their University careers have to work together in so many new relations, should learn to do so at the University stage.

We do not, indeed, wish to suggest that co-education should be universal in the medical schools. Among the consequences which might result from the adoption of such a policy would be that in some schools there would be only a very small number of women—perhaps only one woman. Such a condition of affairs would on various grounds be highly undesirable. There should in our view be three types of clinical education: (1) for men only, (2) for women only, and (3) for men and women. This involves the maintenance as men's schools of certain existing schools, the maintenance of at least one women's school, such as the London School of Medicine, and the provision of facilities for co-education.

The field, however, is not clear. The existing medical schools, though schools of the University, came into existence before the reconstitution of the University, and some of them are of great age with long traditions to which they are naturally strongly attached. Speaking generally, they originated in the hospitals of which they form part, and even now they have not as a rule a separate legal existence,* and their students in the course of their training fill posts in the hospital. They are thus even more independent of the University than are other schools, all of which are autonomous and responsible for their own finances. Further, a large proportion of the students, amounting in some of the medical schools to over 50 per cent., are working for examinations other than those of the University—e.g., for degrees of Oxford and Cambridge or for the diplomas of the Conjoint Board.

The University at present has only one means of enforcing policy upon a medical (or any other) school; it can, subject to appeal to the Visitor, i.e., the King in Council, withdraw recognition of the school and so make it practically impossible for the students to prepare for internal degrees of the University. This power is clearly useless in the present issue. The University cannot make admission of both sexes a condition of recognition for any medical school unless it is prepared to do the same for all medical schools—i.e., to force women upon the schools which have never had them and men upon the London School of Medicine for Women. Logically, moreover, it would be compelled to apply the same principle to other faculties, and force men upon Bedford, Holloway, and Westfield Colleges, all of which are women's colleges, and women on the theological schools, which are colleges for men. It has been said that the University has statutory powers and duties which compel it to provide facilities for co-education, but this is not the case. It is, of course, true that as long ago as 1878 the University obtained a Charter providing that all its powers relating to degrees should apply to women as well as men, and Statute 22 (*e*) prescribes that in making any Statutes, by-laws, regulations, or standing orders, the University shall not impose any disability on the ground of sex. This is, however, only a limitation on the powers of the University; it does not mean and could not without revolutionary change be interpreted to mean that every school of the University must admit both sexes, and still less that it is under an obligation to make provision for all women students who may present themselves. The new Statutes make no change in this respect.

When the new Statutes come into force the position of the University will be different in one respect—namely, that the Treasury grant which is at present paid direct to the medical schools (see Table V.) will in future be paid in a lump sum to the University. For the reasons already given we do not think that power over grants could be used to compel a medical school to remain or become co-educational against its will. The arguments against withdrawal of recognition as a means of enforcing co-education apply with almost equal strength against withdrawal of grants. On the other hand, the control of substantial sums will put the new Court and Senate of the University in a better position to secure by agreement with one or more of the existing medical schools, or with a new school, that adequate provision is made for the medical education of women both co-educationally and otherwise.

* St. Bartholomew's Medical College is an exception. This is a separate corporation, established by Royal Charter. One of the clauses of the Charter restricts admission to men students.

TABLE V.

The following figures (report of University Grants Committee) show the amounts received by the medical schools from the Treasury during the year 1926–27:—

PARLIAMENTARY GRANTS.*

School.	Full-time students.			Grants for 1926–27.
	Men.	Women.	Total.	
Charing Cross	38	45	83	£2,100
King's College Hospital ..	140	67	207	2,950
London	337	9	386	13,950
London School of Medicine for Women	—	298	298	11,750
Middlesex	196	—	196	5,900
St. Bartholomew's ..	592	—	592	16,400
St. George's	82	—	82	950
St. Mary's	171	57	228	10,760
St. Thomas's	367	—	367	13,130
University College Hospital	197	59	256	15,500
Westminster	40	30	70	550

* *Note*—Guy's Hospital Medical School is not in receipt of Parliamentary grant.

Co-education, if it is to succeed, must be voluntary. Before the war the tradition or policy of the medical schools was opposed to co-education, and its introduction during the war was due to the initiative of the schools, though it was welcomed by the University as being in accordance with its own policy. Its restoration can, we are convinced, only come about by an agreement between the University and the schools and possibly by an arrangement by which the several schools would agree to a certain quota of women students.

RECOMMENDATIONS.

It is recommended: 1. That the foregoing report be generally approved and that copies be forwarded to the schools in the Faculty of Medicine and to such other bodies and persons as the Vice-Chancellor may direct.

2. That, in communicating the foregoing report to the schools in the Faculty of Medicine other than University College Hospital Medical School and the London School of Medicine for Women, the Vice-Chancellor be requested to invite them to consider the possibility of admitting a quota of women students as a means of giving effect to the policy of the University as set out in the report, and that no communication of any kind be made to the press except on the authority of the Vice-Chancellor.

The report is signed by Sir William Beveridge, the chairman.

MEDICINE AND THE LAW.

Inquest on Christian Scientist.

AT an inquest recently noted in this column the parents of a young man, for whom medical aid had not been provided, were warned by the coroner that, if their son had been 15 years of age, they would have been liable to indictment for manslaughter notwithstanding their bona fide belief in Christian Science. This belief, and the consequent refusal of medical aid, came again into prominence at an inquest at Oxford on Jan. 23rd. The deceased was a widow who had for many years been a Christian Scientist. Her son-in-law gave evidence that she entered Coston Hall, a Christian Scientist nursing home, last October.

He could find out nothing about her health because her attitude was that there was nothing wrong with her and that she would have no medical aid. He asked the superintendent of the home for a medical report, but received the reply that in such a home there could be no medical examination and no medical report. He afterwards took her from the home and obtained the services of a medical practitioner for her, though she was evidently reluctant to avail herself of them. The practitioner, Dr. J. F. West, in issuing the death certificate, gave as the causes of death dysentery, extreme wasting, and Christian Science. He explained that he added these last words in order to ensure a coroner's examination of the case. His evidence was that her condition was definitely aggravated by the neglect to provide medical aid. Here it may be borne in mind that one of the cases which a registrar must report to a coroner before registration of a death is "any death which the registrar has reason to believe to have been unnatural or directly or indirectly caused by any sort of . . . neglect." It is clearly the duty, therefore, of the certifying doctor to show upon his certificate in some form the fact of neglect which in certain circumstances is a criminal matter.

As stated in the previous case, the legal rule is that it is manslaughter to cause death by neglect to supply necessary food, care, and medicine to children, prisoners, or helpless persons where a legal duty towards them exists by statute or contract. The case of children is clear; the case of prisoners was illustrated when a former Home Secretary defended himself in argument against criticisms of his having ordered the forcible feeding of hunger-strikers. The case of helpless persons is perhaps more obscure. In the Chattaway case in 1922 a man and his wife were charged with manslaughter of their daughter, aged 25, who had returned to her parents' home ill and weak. They allowed her to stay but neglected her, and she became too ill to leave them or to get help. They were sentenced to five years' penal servitude, and the Court of Criminal Appeal said the daughter was as helpless as an infant; the question of helplessness, added the judges, was one for the jury; there was a common law duty to take proper care of an adult who was helpless and could not withdraw from the control of persons having charge of him or her. In R. *v.* Shepperd, an older case, a mother deliberately neglected to procure proper attendance for her unmarried daughter, aged 18, in the latter's confinement, this neglect causing death in childbirth. It was held that, although the daughter was living with her mother at the time, and though the mother could have got medical aid gratis, there was no such breach of duty as would render the mother liable to conviction for manslaughter. In the recent case at Oxford it might be supposed that insurance companies would be inclined to regard the death as one of suicide, and in popular language the management of the home might be spoken of as having aided and abetted self-destruction. There is, however, no element of criminality in the keeping of a "Christian Science house"; indeed, such institutions obtained a form of recognition from Parliament when they were expressly exempted from the Nursing Homes Registration Act of 1927. The relation between the superintendent of the house and the voluntary inmate is contractual not statutory. And the contract presumably is not for the provision of such food, care, and treatment as a medical practitioner would reasonably recommend when a patient is in ill-health, but for something conspicuously different.

Two anonymous donors have given £5000 to Edinburgh Royal Infirmary in memory of Dr. A. B. Smith and Dr. S. McK. Smith. It is to be used in connexion with the proposed Radium Institute. Sir Stanford London, president and chairman of St. Paul's Hospital, Endell-street, London, has given £1000 to this hospital to start a memorial fund to the two brothers, who died immediately after their association with its work had been arranged.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Local Government Bill: Maternity and Child Welfare.

THE House of Commons went into Committee on Wednesday, Jan. 23rd, on the Local Government Bill, Mr. J. F. HOPE (Chairman of Committees) in the chair.

Discontinuance of Grants.

On Clause 68 Mr. GATES moved an amendment to exclude the maternity and child welfare services from being discontinued grants, and to keep them, as at present, on the percentage system, instead of bringing them under the block system. There were, he said, very good reasons why this should be reconsidered by the Ministry of Health. The actual cost of the maternity and child welfare grant last year was only £1,052,000. The service was a young and growing one, and of great importance. The antenatal work was only just beginning to be considered under the maternity schemes, and maternal mortality had hardly been considered at all under these schemes. The expenditure was growing, having increased 36 per cent. in the last five years. The medical officer of the Ministry of Health (Sir George Newman), in his latest report, stated that 25 per cent. of the young children entering the elementary schools to-day were suffering from some physical defect which could have been prevented had they had better treatment before entering school. Hitherto 50 per cent. of the expenditure had been borne by the Ministry itself, but under this Bill a block grant would be made to the appropriate authority which would itself decide how much of the money should be spent in maternity and child welfare work, and the question naturally arose whether these services would receive an adequate proportion of the block grant to allow for the much-needed expansion of the work, and how far there was security under the Bill against local factors operating to restrict expenditure and thus hinder its progress. The block grant was originally fixed for a term of five years, but he was glad that the Minister was proposing to alter that and make the first period three years, the second four years, and the subsequent periods five years. Those who were interested in maternity and child welfare regarded this as a great improvement, because many things might happen in five years. But even three years was a considerable time, and if during that time it was necessary to expand these services, the cost would have to be defrayed out of the rates. That would be a serious disadvantage to the successful prosecution of the maternity and child welfare services. It had been said that at present a richer borough spent more because of the percentage grant, and the necessitous borough spent less. He was not prepared to admit that that was true, but if it were true now, it could not be true after this Bill came into operation, because there would be the large sum of £45,000,000 to be distributed among the boroughs according to their necessity. It had also been suggested that the percentage system implied a considerable amount of official interference with the local authorities. He had been interested in local government for many years, and he had never heard anything but praise of the official interference of the officers of the Ministry of Health in connexion with work such as maternity and child welfare. Another point was the work done by voluntary associations. Those associations considered themselves very much discouraged by this Bill. He hoped that the Minister would be able to give them some comfort in regard to the future. Some of them had received grants from their local councils, but not all, and in every case they had received from the Ministry 50 per cent. of their approved expenditure on maternity and child welfare work. That, of course, passed away under this Bill. He did not think that the Minister had enough power to see that these associations were recognised by the local authorities to whom in future they would have to look for assistance in their work. Those who were associated with him in moving this amendment were not in the least degree inspired by hostility to the Minister of Health, to his Department, or to the Bill. There was much in the Bill which they all liked. But he would point out that there were many services which would still continue to be run on the percentage grant system. Resolutions in support of the amendment had been sent to him from all sorts of societies, including the National Council of Women, the Society of Infant Welfare, and the Ragged School Mission. It was also supported by the Society for the Care of the Unmarried Mother and her Child, of which Mr. Chamberlain was the President.

Development of Welfare Service.

Mr. A. GREENWOOD said that the Labour Party were fully in agreement with the amendment. Every social

service to-day was undergoing development, and that was particularly true of maternity and child welfare. There was not a single health service, however, which had been utilised to the extent that Parliament permitted, and any step which under these circumstances would tend to hinder even one local authority from continuing to develop its work must be disastrous to the social services of the country. On April 1st of last year there were 847 antenatal clinics struggling with a mass of work with which they could not possibly cope effectively. As a matter of fact there was room for 1847 such clinics, or even more than that. The financial clauses of this Bill, which constituted the real partnership between the State and the local authorities, were delivering a felon's blow against that particular service, which was not even extracting 10 per cent. of its possibilities. He did not pretend that the percentage grant system was in itself an ideal one. But the system was condemned by the Treasury not because it was not assisting social services —indeed it was doing it too well—but because it meant the expenditure of State money. Every new development of maternity and child welfare work after the grant had been fixed would be entirely a local burden, and under such circumstances did the Minister suppose that hard-pressed local authorities would undertake the developments which many of them desired?

The Countess of IVEAGH said that there was a great deal of diversity of opinion on this subject among women who were interested in these particular services. She admitted, however, that there had been apprehension as regarded the possible operation of the block grant versus the percentage grant, and that seemed to be chiefly based on the assumption that it was easier to induce a local authority to develop a health service if they could offer that authority something in the nature of a good bargain. Of course, that only applied to the areas which could afford to take advantage of the bargain offered, and it could not be denied that it was the richer areas which had benefited most under percentage grants. If the arguments for this amendment were sound, she could not see why they should not apply to all the health services, and not merely to maternity and child welfare. But the exempting of all health services would, of course, whittle away the whole basis of the Bill, and leave the present inequality between the richer and poorer areas. Under the Bill a much larger sum of money would be at the disposal of the poorer areas, and under another clause the Minister would be in a position to say to a local authority, "You have now more money, and it is up to you to provide a reasonable standard of efficiency in discharging these functions." She urged hon. Members to trust the Minister to put Clause 86 into operation in such a way that they need have no fear of the development of those services which many of them had so much at heart.

Mr. HARRIS said since child welfare had been started the death-rate per 1000 had gone down from 105 to 7. There was still a tremendous amount of work to be done. A number of boroughs in London were very much behind, and there were whole districts which were not adequately catered for. If there was anything for which an exception should be made, surely it was this new pioneer work of looking after the mother at a critical time in her life.

Objections to Percentage Grant.

Dr. VERNON DAVIES said that he was sure that Members on both sides of the House were anxious that nothing should be done to interfere with the development of this service. He was definitely opposed to the percentage grant for this service and in favour of the block grant. Under the percentage system the money was not given according to need, but simply according to ability to pay. Moreover, percentage grants tended to encourage extravagance among local authorities. One could always be extravagant with a service when one had only to pay half the cost. There was also the other very grave objection that a percentage grant necessitated very careful Government control of expenditure. Percentage grants were given in the first place as a stimulus for the development of a service. The essential nature of the stimulant was that it was temporary; if they made it permanent it tended to become a narcotic, and there was a danger of this happening with maternity and child welfare. The percentage system had been in existence for some time, and all local authorities had had the opportunity of taking advantage of it, yet a very large number had not yet done so. In certain cases, owing to lack of interest in the service, they had not troubled even to start it. In other cases, in wealthy districts, there had perhaps been the fear of an increase in the rates which had prevented them from taking the service up. But the main cause, he thought, had been the poverty of different districts. They could not afford to pay their 50 per cent. quota, and it was on behalf of the poorer authorities that he thought they should welcome the action of the Minister in bringing in the block grant. He had noticed more than once that there was a tendency in the House and in the country to value the success or otherwise of a service by the amount of money spent upon it, and to say that if the expenditure increased by 10, 15 or 20 per cent., the service of necessity was improved. But increased expenditure did not necessarily mean increased efficiency, and the point which they had to consider, particularly in regard to the block grant system, was, would the money be sufficient for the service, and they had the assurance of the Minister of Health on the second reading of the Bill that that was the case. No one could legitimately say that these services were going to be starved for want of money. The money would be there under the block grant if the public cared to have it. By Clause 86 the Minister was given such power that he could either initiate or see that these services were carried on in an efficient manner. He (Dr. Davies) thought that public opinion, knowing of the new money that would come into the district by means of the block grant, would begin to insist upon local authorities using it for this specific purpose, and that would have a very marked effect. He had initiated and carried on such a service, and it was as a result of his experience that he was convinced that the day of the percentage grant for maternity and child welfare was over. The personnel in welfare service was very much more important than money. As far as he could see, the result of block grants would be, first of all, an increased number of centres, particularly in necessitous areas which up to the present had not been able to afford them. They would also find that there would be an efficient standard in all the centres.

Funds for Health Services.

Miss LAWRENCE said that Lady Iveagh had said that poorer authorities would have plenty of money to spend, and that the Minister would have power to enforce health services. Both these remarks were entirely and completely mistaken. What guarantee was there that local authorities were to get anything extra? They were to have a minimum of a shilling per head of the population over what they had lost on the standard year 1928–29. What was a shilling per head of the population? They had no detailed figures, except in regard to the county boroughs. The amounts they actually got in rate relief were in some cases 1*d.* and in some 1½*d.* The best was 2½*d.* The formula did not in the least correspond with the distinction between rich and poor. The incidence was so capricious that some rich places might gain a great deal and some poor places, under the unrestricted operation of the formula, might lose a great deal. But even supposing that for the first three years the poorer districts got a penny or twopence off the rates, that was not very much. This had to account for all the losses with regard to the possible rise in rateable value of properties, and to account for all the new road work, maternity work, tuberculosis work, venereal disease work, and the rest. That little extra would leave some of the districts worse off if they did anything at all commensurable with regard to their health services. Lady Iveagh seemed to be under the impression that Clause 86 gave the Minister power to insist upon the maternity work being undertaken. It did not do so. No clause asking for a reasonable standard could turn optional services into compulsory services. No words said with regard to the maintenance of a reasonable standard of health could undo the express action of Parliament, which had made venereal disease, maternity benefit, and tuberculosis optional services. This was a very badly drafted clause. Sir George Newman in his report for 1927 said:—

"There can be no doubt that the percentage Exchequer grants-in-aid on health services (Tuberculosis, Maternity and Child Welfare, Welfare of the Blind, Venereal diseases, Mental Deficiency, and the School Medical Services), have been of the highest possible value and incentive during the last 15 years, (*a*) in getting special medical services into operation, and (*b*) in guiding their direction. Those two advantages would not necessarily be lost by a system of quinquennial block grants, though some definite adjustments of administration will be necessary to secure them."

A block grant was quite a different thing from a fixed grant. A block grant every five years on a programme might be a very good thing indeed. In their evidence before the Royal Commission on Local Government the Ministry of Health said:—

"As is to be expected from the permissive character of the Maternity and Child Welfare Act . . . the schemes at present being administered differ widely as regards their efficiency and completeness. It has been the policy of the Minister and his predecessors to stimulate local authorities to initiate schemes, and so on."

There was no power to compel these authorities or to force what was an optional service on them. The position of the health grants to voluntary societies was also extraordinarily unfortunate. Some local authorities had already expressed the opinion that it was unfair to give grants which really belonged strictly to their own residents to a national society. That feeling, unreasonable as it might be, was very strong. Lady Iveagh seemed to think that it was a reductio ad absurdum to say that they must care for the sufferers from

tuberculosis, care for the blind, treat venereal disease, and take over the care of mental deficients. The Labour Party stood for the logical extension of the principle. Those interested in the question of mental deficiency had pointed out that the grants for that purpose were similar to those for maternity and child welfare. They had pointed out the deplorable state of the child mental deficients and the adult mental deficients who were not looked after. Take the case of venereal disease. So reluctant were local authorities to take up the question that a grant of 50 per cent. was not enough; 75 per cent. had to be given. Did the Committee think that local authorities who had been bribed by such an enormous percentage to undertake this work were going to carry it on when they had to take every additional penny they spent on it out of the block grants handed over for other purposes? What were powers of compulsion, even if the Minister had such powers? Unless the authorities were really willing they could not get them to do the work. It was desired by every local authority that the percentage grants should continue.

Sir D. NEWTON said that that morning, at a meeting of the County Councils' Association, reference was made to this question, and the Association were unanimously of the opinion that mental deficiency and maternity and child welfare should not be excluded from the block grant system. He did not believe that this change would be to the detriment of the maternity and child welfare service; on the contrary, he believed that the proposal would tend to stimulate the interest of local authorities in the service. It would be better, too, for many of the voluntary associations concerned. At present in many cases voluntary associations interested in maternity homes had to make application to numerous different boards of guardians for assistance, but in future such associations would be able to apply to the major authorities, who were more readily approached and would be more likely to be sympathetic.

Miss WILKINSON said that the Minister of Health had provided under the Bill that the extension of the road services must be left on the percentage basis. If that was necessary for that service it was infinitely more so in the case of a service which concerned the lives and welfare of children. She desired that the mothers and children of the slums should have the best that medical science and service could offer. Maternity and child welfare was a new service which was not organised. It depended on groups of women and medical men who realised its importance, and she appealed to Mr. Chamberlain to remove the service from the block grant system.

Viscountess ASTOR said what she was anxious about was the extension of health services under the block grant. Those services had not grown because of popular demand; indeed they had grown in spite of general apathy, because they had been inspired by the central authority working mainly through voluntary associations and local authorities. The lead had generally come from the central authority, and she felt that the service was now going to be left entirely to the local authorities. Very seldom did local authorities move unless they were prodded by the Ministry of Health. What was the Minister going to do about new services under the block grant system? They found it difficult enough to get expansion under the percentage system, and they did not want to make things more difficult. There was the tremendous problem of children between 1 and 4 years of age. Last year 82,000 children under 14 years of age died, and 23,000 died between the age of 1 and 4.

The Minister's Reply.

Mr. CHAMBERLAIN, Minister of Health, said that he did not think that there was any difference of opinion between Members on opposite sides of the House as to the value and importance of the maternity and child welfare services, the results of which had been so remarkable, and of which every one of them felt proud. It was inconceivable, however, that the Treasury should, as had been suggested, seek to impose a change of policy on the Ministry of Health in respect of a service on which it could only gain a few hundred thousand pounds. Do not let them be too abstract and theoretical about these matters. They might very well find that one system of grants was best for one kind of service, and another system for another service. He judged the question of block grants or percentage grants on their merits as applied to particular services. In his view, it was in the best interests of the maternity and child welfare service that they should change the present system. He assured the Committee that at the Ministry of Health, where he was not looking at one particular locality but where he had to consider the reports coming in from all localities, he did not find the present system satisfactory. He did not find that where the local authorities were indifferent or niggardly the offer of pound for pound was sufficient to make them "willing" to take up a service. That was just the trouble. On the contrary, many authorities remained unwilling, and in those circumstances he had no power to compel them. That was the key and kernel of the whole situation, and provided the reason why it was impossible to get along faster under the present system. He would quote one or two figures to show how the present system worked. They were figures of the grants per child under 5 years for the year 1926–27. They affected four towns: Gateshead, 27*d.* per child; Dudley, 21*d.*; Tynemouth, 36*d.*; Merthyr Tydvil, 43*d.* No one would say that these towns were not poor or that they were not just those towns where there ought to be very good services. Here were others: Manchester, 128*d.* per child; Liverpool, 107*d.*; Leeds, 140*d.*; Eastbourne, 200*d.* How could they defend distribution of that kind? Was it likely to encourage the institution of adequate maternity and child welfare services in those poor districts? The amount of money required per head to give an adequate maternity and child welfare service was very little, and trifling compared with such things as education and roads. In the vast majority of cases there would be no guarantee of a shilling per head because the gain under the scheme was going to be much more. But the shilling per head would be a guarantee to the few places which were not going to gain a great deal more. In future, therefore, it would not be possible for a local authority to say that they could not afford to have a proper maternity and child welfare service, because they were going to have sufficient money under the scheme to enable them to give sufficient services.

Miss LAWRENCE: How much of this money is going to these services?

Mr. CHAMBERLAIN said that would be for the local authority to determine. But having provided them with sufficient funds he would be able to say to a backward authority that it must bring its service up to the proper standard. It was true that he could not force local authorities to give adequate maternity and child welfare services, but if he had a lever before in being able to offer them something on condition that they spent a little themselves, he would have a much more powerful lever under this Bill, for he could take away from them that which they had got, and there was no limit to the amount of their grant which he could take from them. But he did not think it would be necessary to go to extremities, because no local authority would resist a reasonable demand for adequate services of this character, and no local authority would risk the loss of a grant which would in future form a large part of its whole income. He thought that some of the bodies which had passed resolutions on this subject had been a little hasty and had done so without hearing both sides. Some of them, when they understood better what it was proposed to do, had changed their minds. He wished to say that he attached great importance to the work that was done in this connexion by the voluntary associations. He had the greatest admiration for their work. He had always been in favour of the associations between voluntary workers and municipal workers in social matters. Anything that would destroy a partnership of that kind would be unfortunate and wrong, and he was therefore very anxious that the voluntary associations should be assured that their interests had been properly looked after in this Bill. The Minister under Clause 83 was brought in to protect their interests. These associations must not suppose that the guiding hand of the Ministry was being withdrawn. The inspections of this work by officers of the Ministry of Health would continue though in a different form, as in the past. The Minister would be kept in close touch with the work which these associations were doing, and although in the future they would get their grants from the local authority, the Minister, whose approval of the scheme had to be obtained, would be able to see that their interests were properly looked after. He proposed to add a new clause to the Bill under which it would be possible for a voluntary association who desired to extend its services to make a representation to the Minister, who would have power, after consultation with the local authority, to call for the scheme which had already been approved and to alter it as he thought fit. That ought to meet the point which had been made that whilst schemes that were approved at the beginning of a fixed period might be adequate in themselves and for that time, yet there was not sufficient room for expansion under the Bill as it stood. With regard to new services, if Parliament should impose on local authorities a new service which meant new expenditure, clearly it would be only just that Parliament should make some provision for an additional contribution from the Exchequer towards the cost of that service. He had now put down a clause which made this quite clear. In conclusion, the right hon. gentleman asked the Committee to consider whether the present situation of the health services under the percentage system was so satisfactory that they could be content to go on in the future as they had been doing in the past. After all, the whole of the changes which would be produced by this Bill would have to be reviewed before many years were over, and there would be an opportunity then to compare the working

of the old system with that of the new, and in those circumstances surely it was wise to accept the provision in the Bill as it stood.

After further debate

A Great Advance.

Lieut.-Colonel FREMANTLE said he hoped that he might be allowed to make a few remarks as an old medical officer of health who had been in close touch with these voluntary associations, and in active coöperation with them for 30 years. When the first general lines of the Bill were announced he shared the very great anxiety which had been expressed at the abolition of the percentage grant. He would say no more at present than that under certain conditions he was convinced that the Bill as a whole was a very great advance, and they had to make the most of it. But there were two points which had not been mentioned. Members of the Opposition who had spoken with such warmth on the subject of ideals which were common to them all seemed to have left out of account the question of the distribution of the grant which was the alternative to the percentage grant which they were advocating. When they were contrasting the percentage grant and the block grant it was essential to bear in mind that the Bill introduced into what had been roughly called the block grant the new principle of weighted population. Medical officers of health looking at the thing from the point of view of the health of the people must recognise that an extraordinarily interesting new factor was introduced into the world of administrative public health. This weighting of the population according to the number of children under five years old, and the number of unemployed, had very great possibilities. It was obvious that there would be a great deal more money in the new Bill, and it was germane to consider how it was going to be distributed in future. This Bill would be extraordinarily helpful in dealing with really indigent people. Obviously a great deal depended upon how the local authorities were going to use the powers given to them under this Bill. If they looked honestly at the measure as a whole there was a great opportunity for getting greater interest and responsibility, and for focusing attention on local government on business lines. He did not believe that there was going to be a revolution, but it would give a very large measure of support in that direction, and, coupled with the enormous extension of the franchise, it would give an opportunity to press upon the electors the responsibility which was thrown upon them, and with an increased public interest in local government they would be able to trust the local authorities to carry out the block grant system properly and with very great advantage compared with the present system. In that sense he looked forward to the Bill being the magna charta of local government.

After further debate the amendment was rejected by 206 votes to 130.

The clause was added to the Bill by 200 votes to 120.

General Exchequer Contributions.

On Clause 69 Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) moved an amendment to give effect to the new proposals which had been made by the Government after consultation with the local authorities providing that the first two periods for which a general Exchequer contribution would be fixed would be three and four years instead of five years as originally proposed. These two periods would be followed by two periods of five years. The result of this amendment would be that the total period for transition to the full working of the formula would be extended from 15 to 17 years. Thereafter the grant periods would be quinquennial periods, and it was proposed that after 1931 the census should be taken at quinquennial intervals, so that the distribution of the grant would be based on census figures instead of estimates. The next census would be taken in 1931.

Miss LAWRENCE moved to reduce the first period from three years to two years.

Miss LAWRENCE's amendment was rejected by 177 votes to 112, and Sir K. WOOD'S amendment was agreed to without a division.

The House of Commons on Monday, Jan. 28th, continued its consideration of the Local Government Bill in Committee.

On Clause 83, which deals with

Contributions by Councils to Voluntary Associations

in respect of maternity and child welfare, Sir LESLIE SCOTT moved an amendment to impose a statutory obligation on county and county borough councils to consult with voluntary associations doing maternity and child welfare work before framing their schemes.—Mr. CHAMBERLAIN, in reply, said that the amendment was quite unnecessary, because it was impossible—and that must be evident—for any council to frame a scheme of that kind without consulting the voluntary association. The clause provided that the county councils or county borough councils should prepare schemes for securing payments by them of annual contributions towards the expenses of voluntary associations. In order to know what these expenses were, the councils must know what the associations were doing, were able to do, and proposed to do in future. The Minister of Health also had to approve of the schemes, and if the schemes were submitted without consultation with the voluntary associations, it would be open to the associations to represent to the Minister that they had not been consulted.—The amendment was withdrawn.

Mr. HURST moved an amendment giving power to the Minister of Health to include in the schemes prepared by county councils provisions whereby contributions towards the costs of inmates in a maternity home within their areas might be enforced against the council of any other county or borough where an inmate normally resided before entering the home. He said that the amendment would enable the unmarried mother to avoid local scandal by going into a home at a distance.—Mr. CHAMBERLAIN said it would be a mistake to make it more difficult for maternity homes to take in unmarried mothers from other localities. In the past, direct grants had been given from the Exchequer to the homes, but in future the grant would be given to the local authority in whose district the home was situated. The local authority would not have discretion to spend the money on anything else. For seven years it would receive 75 per cent. of the grant previously given, for the next five years 50 per cent., and for another five years 25 per cent. The amendment was rejected, and the clause was added to the Bill.

Clause 84 provides for contributions by councils to voluntary associations in respect of other health services. Sir L. SCOTT moved an amendment providing that the Minister should, before the beginning of each fixed grant period, make a scheme providing for the payment of contributions by councils of counties and county boroughs of such amounts, as might be specified in the scheme, to voluntary associations which undertook to provide, centrally or locally, services for the welfare of defectives, including the ascertainment, assistance, or supervision of mental defectives whilst not in institutions. He said that as the clause now stood some of them feared that it might have the effect of limiting the services for which the grants under the clause might be given. A great deal of the best work in connexion with mental defectives was done outside the local authorities, and he wished to make sure that there would be no limitation in future in grants for work done by way of assistance to the local authorities.—Sir T. INSKIP (Attorney-General) said he could give Sir L. SCOTT the assurance which he desired. The amendment was accordingly withdrawn.

Sir KINGSLEY WOOD moved an amendment giving power to the Minister of Health, after consultation with the local authority concerned, where it was desired to start or further a maternity or child welfare scheme, to alter the scheme so as to provide for such contributions or increased contributions as he considered just. He said that with this amendment and the original clause in the Bill the Government were giving a very strong position to the voluntary associations carrying out this work.—Dr. FREMANTLE said that his name and that of Major Hills were down to an amendment earlier on this clause, but he purposely did not move it because this amendment covered the same ground. He had tabled his amendment because the clause did not provide for the future expansion of this service. It was put down on behalf of the Midwives' Institute and the Queen Victoria Jubilee Institute for Nurses. Those professional bodies, which were largely neglected by public opinion, were at the bottom of the working of these maternity associations, and they would, he believed, be abundantly satisfied by this amendment. He hoped that there would be a possibility of covering now, for the first time, the whole of the counties with the work of the county nursing associations in nursing and midwifery.

Sir W. GREAVES-LORD moved an amendment providing that the Minister of Health should, before the beginning of each fixed grant period, make a scheme providing for the payment by county and county borough councils of such an amount as might be specified in the scheme to the central council of an approved organisation which provided services, in the nature of general publicity and educational propaganda, in furtherance of the prevention and treatment of venereal disease. He said that he could not understand why the Government had thought it necessary, in the Bill, to take a course which would destroy to a large extent the activity of one voluntary association—the British Social Hygiene Council—whose work had been recognised not only by the Government but by the Royal Commission on Venereal Disease, and which had been carried out to the expressed satisfaction of the Ministry of Health. Under the Bill, other health services, such as maternity and child welfare, the care of mental defectives and of the blind, would be materially affected if anything was done to diminish the efficiency of the measures taken for the prevention and

urative treatment of venereal disease. Most valuable work in regard to propaganda, advertising in the public press, and the exhibition of films had been carried on by the British Social Hygiene Council. They had undertaken work which no local authority could carry out. Within the last few weeks inquiry had been made from a number of medical officers of health, all of whom stated definitely that they considered that public enlightenment on venereal disease was essential. The amendment would enable the Ministry to make an equitable scheme, which would provide for a contribution based upon 5*s.* per 1000 of the population. If that were impossible, however, and the Minister could deal with the matter as he desired in Clause 86 of the Bill, he would be content.

Sir KINGSLEY WOOD resisted the amendment. He said that Sir W. Greaves-Lord was seeking—following, he supposed, the precedent already established in relation to the maternity and child welfare services—to secure that the local authorities should be obliged to pay an annual contribution to the British Social Hygiene Council, or some corresponding body. The Minister of Health shared with the mover of the amendment his appreciation of the work which that Council had achieved. Undoubtedly it had done very good service, especially in the earlier days when that kind of work was much more unpopular than at present. But, on the other hand, they must look at the position so far as the local authorities were concerned. Those authorities were to a very large extent actively engaged in the work of stamping out the disease. During the present year some £7500 had been spent by the local authorities. Many local authorities desired to include venereal disease as one of the subjects in their general scheme of health propaganda. There was a great distinction between the position of voluntary agencies which were carrying out maternity and child welfare work and pure propaganda work. The responsibility for the health services rested with the local authorities, who would strongly resent being obliged to contribute towards the expense of a service which they might not care to apply.

After further discussion, in which Lieut.-Colonel Fremantle supported the claim of the British Social Hygiene Council to a grant from local authorities (see p. 248), the amendment was rejected by 204 votes to 95.

Reduction of Grants to Councils.

The House of Commons on Tuesday, Jan. 29th, again went into Committee on the Local Government Bill. On Clause 86, which gives power to the Minister of Health to reduce grants to councils, if he is satisfied that a council has failed to achieve or maintain a reasonable standard of efficiency in the discharge of its functions relating to public health, Sir LESLIE SCOTT moved an amendment to insert the words "and progress" after "efficiency." He said that the amendment would help the Minister of Health to see that a reasonable standard of progress as well as static efficiency was maintained by the local authorities.—The amendment, which Mr. CHAMBERLAIN accepted, was agreed to.

With a view to defining the public health services which the local authority was obliged to maintain at a reasonable standard of efficiency and progress, Mr. CHAMBERLAIN moved an amendment to insert, after "public health," the words "including services relating to maternity and child welfare, lunacy, and mental deficiency, and the welfare of the blind." He said that tuberculosis and venereal disease were recognised as being covered by the words "public health," and in order to remove any question as to the others he moved their inclusion in the term. The amendment was agreed to.

Sir L. SCOTT moved an amendment to delete from the clause the proviso that the Minister of Health, when dealing with the question of the reduction of grants, must have regard "to the standards maintained in other areas whose financial resources and other relevant circumstances are substantially similar." The words, he said, might be used to tie the hands of the Minister unduly when dealing with the backward authorities. Sir K. WOOD said that the amendment would untie the hands of the Minister for the time being altogether and the operation of the clause would be entirely at his discretion. He could imagine a kind of Minister who might have a very different idea of the standards to be observed in putting the clause into operation. The amendment would also make the point still more difficult from the point of view of the local authorities. The amendment was withdrawn.

On an amendment moved by Mr. LUMLEY, Mr. CHAMBERLAIN said he would consider the possibility of introducing words into the clause to give an opportunity to some outside persons to make representations to the Minister as to the failure of a council to achieve or maintain a reasonable standard of efficiency in the discharge of their public health functions. Such words, however, would have to make it quite clear that the Minister was not dependent on receiving that representation before taking action. At 7.30 P.M. the guillotine fell and Mr. Lumley's amendment was negatived. Clause 86 was added to the Bill. Clauses 87 to 92 were also agreed to.

Temporary Loans.

On Clause 94, which mitigates the liability of councils for temporary loans, Sir K. WOOD moved an amendment providing that, to meet the case of the distressed areas, the rate for the repayment of loans contracted by poor-law authorities to be transferred under the Bill should be 9*d.* in the £ instead of 1*s.* The amendment was agreed to, and the clause added to the Bill.

Transference of Officers.

Clause 99 provides that any person who on Nov. 12th, 1928 (the date of the introduction of the Bill), shall have been an officer of a poor-law authority should, as respects his office, be transferred to the new authority. Mr. HAYDAY moved an amendment to allow officers appointed after the date of the introduction of the Bill to be transferred. He said that an obvious injustice to recently appointed officers would be done if the clause remained as at present. With the long periods of distress, and the epidemics of disease which had taken place, quite a number of officers might have been appointed since Nov. 12th, 1928. Sir K. WOOD said that it would be generally agreed that a man appointed to a poor-law office after the introduction of the Bill, and therefore aware of the provisions affecting his office, was not entitled to compensation for its loss. The amendment was rejected. Under the guillotine the clause was added to the Bill, as were Clauses 100 to 110, inclusive. Of these clauses, 103 provides for compensation to existing officers, and 104 for superannuation of transferred poor-law officers.

The Committee adjourned until Wednesday, Jan. 30th.

HOUSE OF LORDS.

TUESDAY, JAN. 29TH.

Protection of Animals (Amendment) Bill.

This Bill passed through its Committee stage. As amended, it provides that if the owner of any dog should be guilty of cruelty within the meaning of the Protection of Animals Act, 1911, the court, on his conviction, might, in addition to any other punishment, order that the owner, for such time as they directed, should not be granted any licence to keep a dog, and if in spite of that he applied for and got a licence, he could be further proceeded against.

Road Vehicles Regulation Bill.

The House of Lords referred this Bill, which has been read a second time, to a Select Committee of the House. It was stated during the discussion that everyone recognised the need of mitigating the large number of accidents which occurred through motor traffic. The MARQUESS OF SALISBURY stated that the Royal Commission on Transport, now sitting, had undertaken to present an interim report in June or early in July.

HOUSE OF COMMONS.

WEDNESDAY, JAN. 23RD.

Mental Hospitals for ex-Service Men.

Mr. SMEDLEY CROOKE asked the Minister of Pensions if he would consider the advisability of giving institutional treatment in a home provided through the Ministry by the State to those ex-Service men who through war service were now housed in pauper lunatic asylums, providing treatment somewhat on the lines adopted by the British Legion with ex-Service men suffering from tuberculosis, with the ultimate object of enabling them to resume their ordinary occupations as far as possible.—Lieut.-Colonel STANLEY, Parliamentary Secretary to the Ministry of Pensions, replied: All cases (whether of ex-Service men or others), whose mental condition requires certification, and who may need institutional treatment, are required to be dealt with in the mental hospitals provided for under the Lunacy Acts—institutions the description of which as "pauper lunatic asylums" I deprecate most strongly as both inaccurate and needlessly offensive to patients and their relatives. The hon. Member's suggestion has, however, already been met by the provision of not merely one but two special institutions which, with the assistance of the Board of Control, my right hon. friend was enabled to set up, in 1923, in conjunction with the general mental hospitals. These institutions were specifically designed for those cases in which the Ministry are medically advised that a chance

of recovery or improvement is offered by special treatment in the form of occupational training and instruction.

Poor-Law Relief.

Mr. ROBERT MORRISON asked the Minister of Health the total number of recipients of poor-law relief in 1913 and on the last available date.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: The total number of persons (all classes) in receipt of poor-law relief on Jan. 1st, 1913, was 794,227, and on the latest available date (Jan. 5th, 1929) approximately 1,260,000.

Nursery Schools.

Mr. KELLY asked the President of the Board of Education the number of nursery schools in Lancashire, and the number in England and Wales.—Lord EUSTACE PERCY replied: There are four nursery schools in Lancashire and 27 in England and Wales.

THURSDAY, JAN. 24TH.

Poisons and Pharmacy Acts.

Sir ARTHUR HOLBROOK asked the Home Secretary whether the committee on the Poisons and Pharmacy Acts had concluded its sittings; and, if so, when the report was likely to be published.—Sir W. JOYNSON-HICKS replied: The committee has not yet concluded its sittings, and no indication can be given as to the probable date of submission of its report.

Mental Deficiency Committee.

Sir LESLIE SCOTT asked the President of the Board of Education whether the report of the Mental Deficiency Committee, which on July 9th last he informed the House he hoped would be available before the end of the year, had been signed; and when would it be published.—Lord EUSTACE PERCY replied: The report has just been presented. I hope to publish it as soon as practicable, but I understand it is a very long document, and I should not like to give an undertaking to publish until I have had an opportunity of considering it.

Sir LESLIE SCOTT asked whether they might look for the report well on this side of Easter, because there were important conferences to be held in April which would be attended by many people anxious to know about this matter.

Lord E. PERCY: I will certainly do my best; it is a very long document.

Relief of Distress in Mining Areas.

Sir HARRY BRITTAIN asked the President of the Board of Education whether he could make any statement as to the progress of the organisations responsible for the relief of distress in the mining areas.—Lord EUSTACE PERCY replied: Divisional committees have been formed to control the operations of the Lord Mayor's Fund in the following coalfields: South Wales, Durham and Northumberland, Lancashire, Cumberland, West Riding, Somerset and Gloucestershire, including the Forest of Dean, Nottinghamshire, and Derbyshire. Under the divisional committees, local committees have been, or are now being, constituted as required on a basis fully representative of all interests, including the voluntary agencies, for the purpose of obtaining information, preventing overlapping, and securing fair and efficient distribution. The intention is to incorporate as far as possible any existing distress committees into the local committees of the Lord Mayor's Fund, and to restrict the areas covered by those committees so as to ensure that their members can come into personal touch with those who will benefit from the fund. In areas where the density of distress is not such as to justify the creation of a local committee, it is proposed that the divisional committees should enlist the aid of the local education and public health authorities concerned. As regards the central organisation in London, I would refer my hon. friend to the Lord Mayor's speech at the Mansion House on the 16th of this month, of which I am sending him a copy.

Replying to a similar question in regard to Scotland, put by Captain FANSHAWE, Major ELLIOT (Under Secretary of State for Scotland) replied: The Distress in Mining Areas (Scotland) Fund is being administered by a central advisory committee set up at a conference held in Edinburgh on Dec. 22nd. At a meeting of the central advisory committee, held last week, various decisions were arrived at in regard to the policy to be followed in the administration of the fund, and it is hoped to issue a circular to local authorities this week intimating those decisions. In order to secure uniformity of administration as between the different districts, the committee have fixed a scale of household income to be followed by local committees in considering applications for assistance, a discretion being allowed to local committees to exceed this scale in exceptional circumstances. Assistance from the fund may be given either by way of food (which may include feeding of children at school) or clothing, by assisting suitable persons to move to other areas where employment has been found, or by assisting emigration. The central advisory committee have decided to draw up a list of parishes which, for the purposes of the fund, may reasonably be regarded as "mining areas." Within those parishes assistance from the fund will not be limited to miners, and persons in distress in other industries will be entitled to make application for assistance. Outside these parishes, only the claims of mine workers will be entertained. The central advisory committee have distributed £20,000 to local authorities, representing about one-ninth of the present total of the fund.

The Supply of Radium.

Lieut.-Commander KENWORTHY asked the Minister of Health what steps were being taken to see that an adequate supply of radium was available, especially for the treatment of cancer, for the smaller hospitals, and at a reasonable price; and if any steps were being taken to obtain radium in commercial quantities from within the British Empire.

Mr. ROBERT MORRISON asked the Minister of Health if, in view of the fact that the treatment of cancer by radium was being seriously handicapped by the difficulty of obtaining supplies, he had any information as to the possibility of an increased supply and a reduction in the present cost.—Mr. CHAMBERLAIN replied: I am not at present in a position to add anything to the reply given to a similar question on Dec. 5th, in which it was stated that the whole subject of radium requirements and supplies is under consideration by a subcommittee of the Committee of Civil Research.

Lieut.-Commander KENWORTHY: In the meantime is the right hon. gentleman aware that the matter is very urgent for the smaller and poorer hospitals, in view of the tremendous price that the monopoly is charging for this substance?

Mr. CHAMBERLAIN: Yes, I am quite aware of that, and I am trying to get the report as quickly as possible.

Mr. R. MORRISON: Can the right hon. gentleman, for the guidance of voluntary hospitals, issue a statement of the information in the possession of his Department on the subject?

Mr. CHAMBERLAIN: No, I do not think any useful purpose would be served by doing that.

The Extraction of Enlarged Tonsils.

Mr. ROBERT RICHARDSON asked the President of the Board of Education whether, in view of conflicting medical testimony on the advantage or necessity for the extraction of enlarged tonsils, he would recommend local education authorities to bring to the notice of their medical officers the fact that there was an alternative treatment, and advise them not to prosecute parents who desired to follow such treatment rather than have recourse to the operation.—Lord EUSTACE PERCY replied: I do not think the course suggested by the hon. Member is necessary. The medical officers of local education authorities are well aware that there are various alternative methods of treatment for enlarged tonsils, of which operative treatment is one, and operative treatment would only be recommended by them when other methods of treatment had been tried and failed. The position of the Board is indicated in para. 117 of the report of their chief medical officer for 1921, which was repeated in para. 63 of his report for 1923. I would also draw the hon. Member's attention to para. 118 of the report for 1921, and to para. 64 of the report of 1923, in which it is clearly stated that "the Board of Education have consistently advised that operation should not be undertaken except with the full consent of the parents or guardians of the child."

Mr. THOMAS GRIFFITHS asked the Minister of Health whether, in view of the conflicting medical testimony on the advantage or necessity for the extraction of enlarged tonsils, he would communicate to all infant welfare centres the fact that there was an alternative treatment, and that parents who desired to follow such treatment should not be pressed to have recourse to an operation.—Mr. CHAMBERLAIN replied: It is not the practice at infant welfare centres to advise the removal of tonsils, but rather to refer children needing treatment to a hospital or private doctor for advice as to the appropriate form of treatment. I see no reason therefore, to take the action suggested in the question.

Customs Examinations at Victoria Station.

Sir ELLIS HUME-WILLIAMS asked the Chancellor of the Exchequer whether he was aware that the customs examinations at Victoria Station were carried out on the open platform under circumstances which endangered the health of all concerned; and whether he would cause immediate steps to be taken, either by the Customs House authorities or by the Southern Railway Company, to provide some sort of shelter in which the necessary examination of luggage might take place with reasonable comfort both to passengers

and officers of the customs department.—Mr. CHURCHILL replied: As I have explained on previous occasions, the arrangements and provision of accommodation for customs examination at Victoria Station are entirely matters for the railway company.

Sir E. HUME-WILLIAMS: Is the right hon. gentleman aware that for the last three or four years the railway companies have been promising to make proper arrangements for the convenience of passengers, and will he bring pressure—and it will have to be considerable pressure—to bear upon the Southern Railway to carry out the undertakings given?

Sir H. BRITTAIN: Is it not a fact that the customs proceed more expeditiously here than in any other capital?

Mr. CHURCHILL: I have no constitutional means of bringing pressure to bear on the railway company, but I have no doubt that the authorities controlling that railway will follow the debates in this House.

Sir E. HUME-WILLIAMS: The right hon. gentleman is an optimist.

Mr. SIDNEY WEBB: Would it not be correct to say that the existing arrangements are carried on with the approval of the Commissioners of Customs?

Mr. CHURCHILL: I think that that would be going too far.

Arsenal Worker and Nitro-Glycerine Poisoning.

Mr. WILLIAM THORNE asked the Secretary of State for War if his attention had been drawn to the death of Arthur Leonard Ball, of Stratford, a research worker employed at Woolwich Arsenal; if inquiry had been made as to whether death was due to fumes from nitro-glycerine; and if he proposed to take any action to avoid any future occurrence of this character.—Mr. DUFF COOPER (Financial Secretary to the War Office) replied: Yes, Sir. I have seen a report of the inquest at which the coroner recorded in his verdict that the death was accelerated by the deceased having come into contact with some chemical poison allied to nitro-gylcerine. As regards the last part of the question, I am advised that nitro-glycerine poisoning is an extremely rare occurrence, and may imply a pre-disposition on the part of the individual which cannot, unfortunately, be ascertained beforehand. But instructions are being issued that, if any worker feels indisposed as a possible result of contact with the materials he is using, he must at once report the fact to his superior.

Post-Vaccinal Encephalitis.

Mr. GROVES asked the Minister of Health (1) how the death of the boy Wilson, of Castleford, who died in November, 1928, from post-vaccinal encephalitis, and in regard to whom the coroner investigating the death returned a verdict of death from natural causes, had been classified in the official records; and (2) how the death of the boy Crewe, of Poplar, who died recently of post-vaccinal encephalitis, and was certified as having so died by a doctor at the Poplar hospital, had been classified in the official records, seeing that the coroner at the adjourned inquest on Jan. 14th returned a verdict of death from misadventure.—Mr. CHAMBERLAIN replied: The cause of death was certified by the coroner as "post-vaccinal encephalitis" in the first case, and as "post-vaccinal meningo encephalitis" in the second. Both deaths have accordingly been classified under the heading of vaccinia for the purpose of the Registrar-General's mortality statistics.

MONDAY, JAN. 28TH.

Sleeping Sickness.

Sir SYDNEY HENN asked the Secretary of State for the Colonies whether his attention had been called to the fact that Prof. Kleine had organised an expedition to Tanganyika territory, financed by the German government among others, for the purpose of instructing members of mission stations in methods of combating sleeping sickness; whether he had any information which assured him that this expedition was to operate in agreement with the International Sleeping Sickness Bureau at Entebbe; and, if not, whether he proposed to take any steps to make sure that confusion would not be created in the minds of the native peoples by the possible introduction into that country of conflicting methods of dealing with this disease.—Mr. AMERY replied: Yes, Sir. My attention has already been called to a press report regarding a further visit of Prof. Kleine to East Africa. The International Sleeping Sickness Commission, under the auspices of the League of Nations, of which Prof. Kleine was a member, concluded its labours at Entebbe in June, 1927; and its work is being continued there at the charges of the British East African Governments by the Institute of Human Trypanosomiasis Research. Prof. Kleine is not now directly associated with the work at Entebbe, but I do not anticipate that any confusion would arise if he visited Tanganyika.

Chlorine in Foreign Flour.

Lieut.-Colonel HENEAGE asked the Minister of Health if his attention had been called to the use of chlorine for improving certain inferior grades of foreign flour; and if it was proposed to take any action in the matter.—Sir KINGSLEY WOOD replied: My right hon. friend is aware that chlorine is sometimes used for the treatment of flour, but he understands that its use is diminishing, and having regard to such considerations as the danger of increasing the cost of bread and of driving the milling trade abroad, he is not at present proposing to take any action in the matter.

Recruits for the Police.

Captain CROOKSHANK asked the Home Secretary why the height standard for the Metropolitan constabulary was reduced on Feb. 1st; whether there had been any difficulty recently in securing recruits; whether the establishment of the constabulary was being increased; and, if so, by how many.—Sir WILLIAM JOYNSON-HICKS replied: The reason for the temporary modification of the height standard is the difficulty experienced in obtaining sufficient suitable recruits, above the normal minimum of height, to fill the current vacancies in the force. There has been no recent change of establishment, apart from trifling variations.

Caseous Lymphadenitis.

Mr. W. THORNE asked the Minister of Health if he was aware that during the last six months a certain number of sheep from Argentina had arrived in this country with the glands of the legs and shoulders carefully trimmed out and dressed in such a manner that meat inspectors in Great Britain had great difficulty in deciding whether the carcasses were affected or not with caseous lymphadenitis; and whether he would instruct all inspecting authorities that where they found the vital points for inspection had been removed in this manner they should condemn the whole carcass as unfit for human consumption.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied that the Minister of Health understood that the facts were as stated in the first part of the question. The view adopted by his Department and by local authorities generally was that the removal of the lymphatic glands which were likely to be affected with caseous lymphadenitis constituted sufficient evidence to justify the seizure and condemnation of the carcass on account of that disease. The Minister did not think it necessary to issue special instructions to local authorities on this point.

Supply of Radium.

Mr. R. MORRISON asked the Minister of Health whether, in view of the necessity for an adequate supply of radium, he would state when he expected to receive the report of the subcommittee of the Committee of Civil Research.—Sir KINGSLEY WOOD replied: The subc ommittee would not report to the Minister of Health, and he could not say when their report would be received. But the Minister had arranged for the inquiries made on the subject in the House to be brought to the notice of the subcommittee, and he trusted that their report would be available at an early date.

TUESDAY, JAN. 29TH.

No Children Taken.

Miss WILKINSON asked the Minister of Health whether his attention had been called to the fact that an overwhelming proportion of advertisements of rooms to let in London specified no children taken; and whether, in view of the hardship caused to families whose breadwinners must live near their work, he could expedite the building of flats in place of derelict tenement houses in London, and in the meantime introduce such legislation as would make it illegal to specify no children as a clause in a contract for the letting of apartments.—Sir KINGSLEY WOOD replied: My right hon. friend does not consider that the remedy suggested by the hon. Member would be likely to effect its object. The real solution is to increase the amount of available accommodation, and my right hon. friend understands that the London County Council already have under consideration proposals for the erection of dwellings in London for persons who must reside near their places of employment.

Sanitary Condition of Houses.

Miss BONDFIELD asked the Minister of Health if he would introduce legislation to amend the Housing Act, 1925, so as to place the onus of obtaining a certificate that a house was in proper sanitary condition upon the landlord instead of upon the tenant, so that unless a house was really fit for habitation the 40 per cent. post-war increase of rent would not be payable.—Sir KINGSLEY WOOD replied that this

proposal would involve an amendment of the Rent Restrictions Acts. While the Minister of Health had a good deal of doubt as to the merits of the particular suggestion, he could not, in any case, give any undertaking at this stage regarding further legislation affecting those Acts.

Birth Control.

Mr. THURTLE asked the Minister of Health how many resolutions from organisations and local authorities in favour of the giving of birth control information at maternity and child welfare centres had been received by his department during the period of the present Government.—Mr. CHAMBERLAIN replied that resolutions on this subject had been received from 37 local authorities and from 74 other organisations.

Public Health Services.

INFLUENZA.

As will be seen from the summary which follows, the reported number of deaths from influenza in England and Wales has not risen very rapidly in the last few weeks; nothing, in fact, in anyway comparable with the position in Glasgow. In dealing with a non-notifiable disease such as influenza, it is, of course, difficult to ascertain the actual incidence. The death returns under its own heading and that of pneumonia give an indication of its killing capacity, but the extent to which it is interfering with the work of the country can best be ascertained by actual inquiry of those in general medical practice. Such inquiry has during the past few weeks been made of some hundreds of representative insurance practitioners throughout England and Wales, and the replies indicate that in the last few weeks there has been the usual seasonal increase in "colds," but until the first week in the year there was no report of any influenza epidemic. The first locality to report influenza was West Bromwich, and this was followed by Halifax, Caernarvon, Conisbrough, Bristol, Stockport, Smethwick, Manchester, Wigan, Liverpool, Middlesbrough, Sunderland, Kirkby-in-Ashfield, Dudley, Ashington, Ystrad Mynach, St. Leonards, Stoke-on-Trent, Exeter, Plymouth, Southampton, St. Helens, Nottingham, Lincoln, Luton, and Fleetwood. In all cases the disease was described as of a very mild type, although sometimes associated with otitis media; a severe form is mentioned only at Newton Abbot, where one practitioner attributed the deaths of two young patients to "influenza of a virulent type." Numerous other reports from all parts, including London, state definitely that there is no sign of any epidemic incidence. A large business establishment with about 3000 employees, who live in all parts of London, the suburbs and the home counties, and over 2000 spread all over the provinces, reports an absenteeism certified as due to influenza, bronchial catarrh, bronchitis, and feverish cold of less than 2 per cent.

The Glasgow epidemic has been of a more severe type; the reported deaths from influenza during the week ending Jan. 26th being 236. In Belfast, where the epidemic is widespread but mild, there were nine deaths from influenza during the previous week among 11,000 cases. In the United States of America the epidemic of mild type, which commenced in the Western cities and States about the end of November, and spread across to the eastern coast, is now decreasing throughout the country except in the north-west. The experience of Canada has been similar. On the Continent of Europe influenza of a mild type appeared in Germany in December. The incidence in Berlin increased up to about the end of the second week in January, and is reported as heavy, although the mortality was low. Epidemics, all without exception mild in type, have been reported during January in Norway, Sweden, Poland, Denmark, Spain, Finland, and Italy. Reports from most of the remaining European countries state that there is no epidemic incidence.

INFECTIOUS DISEASE IN ENGLAND AN WALES DURING THE WEEK ENDED JAN. 19TH, 1929.

Notifications.—The following cases of infectiou disease were notified during the week:—Small-po 171; scarlet fever, 2547; diphtheria, 1321; enter fever, 38; pneumonia, 1864; puerperal fever, 42 puerperal pyrexia, 113; cerebro-spinal fever, 16 acute poliomyelitis, 11; acute polioencephalitis, 1 encephalitis lethargica, 23; continued fever, 1 dysentery, 5; ophthalmia neonatorum, 112. N case of cholera, plague, or typhus fever was notifie during the week.

The number of cases in the Infectious Hospitals of th Metropolitan Asylums Board on Jan. 22nd–23rd was follows: Small-pox, 31 under treatment, 1 under observ tion; scarlet fever, 1953; diphtheria, 2097; enteric feve 14; measles, 49; whooping-cough, 658; puerperal feve 24 (plus 9 babies); encephalitis lethargica, 76; poliomyelit 5; "other diseases," 43. At St. Margaret's Hospital the were 18 babies (plus 6 mothers) with ophthalmia neonatoru

Deaths.—In the aggregate of great towns, includi London, there was no death from small-pox, 4 (from enteric fever, 33 (1) from measles, 8 (2) fro scarlet fever, 64 (16) from whooping-cough, 56 (1 from diphtheria, 49 (5) from diarrhœa and enterit under two years, and 179 (39) from influenza. Th figures in parentheses are those for London itself.

The number of deaths from influenza during the previo eight weeks was 49, 56, 60, 61, 69, 83, 99, and 122 respe tively, the rate of rise being slightly steeper in the l week. The deaths from influenza in the week under revi again occurred largely in the midland and northern count —Liverpool, 16; Birmingham, 10; Manchester and Bourn mouth, 6; Stoke-on-Trent, Stockport, and Sheffield, each; Birkenhead and Leeds, 4 each. Glasgow report 151, and Belfast 9 during the same week. The 4 deat from enteric fever outside London occurred at St. Hele Bolton, Manchester, and Bradford. Cardiff reported deaths from measles, Liverpool 6, and Newcastle-on-Ty 5. Salford reported 5 deaths from whooping-cough, H 4, Burnley, Leeds, and Carlisle 3, each. Deaths from dip theria were reported from Liverpool (5), and Birmingha (4). Seven deaths from diarrhœa occurred at Liverpo 4 at Manchester. In the monthly statement of deat from small-pox it is noted that for the month of Decemb one death each was reported from Oswaldtwistle U. and Droitwich R.D., and provisionally classified to small-p

The number of stillbirths registered during the we was 288 (corresponding to a rate of 42 per 10 births), including 51 in London.

ROYAL MEDICAL BENEVOLENT FUND.—As gran are made from the income received from subscriptions a donations, subscribers to this Fund are asked to forw their contributions during the first quarter of the ye rather than later, in order that the amount available distribution may be known and a possible overdraft at t bank avoided. At the last meeting of the Case Commit 35 applications were considered, and 32 grants were vot amounting to over £951. The following is a résumé of th cases:—

An M.R.C.S. died in 1926, leaving a widow and two childr a girl aged 16 and boy aged 13. The widow is now support herself in domestic service. The Fund was asked to assist in education of the two children, £45 being required for the boy £36 for the girl for her last two terms. The Fund voted £40, to each child, and is arranging with other societies to coöper and to contribute the balance required.

Wife, aged 37, of L.M.S.S.A. The husband has had a compl mental breakdown and is subject to dementia paralytica. T wife has no private means and has a girl of 7 years to educ Her father-in-law is making an allowance of £39 per ann whilst the Freemasons are giving £26 and other charities £ making a total of £80. Fund voted £26 and have referred case to the Royal Medical Benevolent Fund Guild to arra for the education of the child.

Daughter, aged 68, of M.R.C.S. Since the death of her fat the applicant has had to live on £53 a year. Bad eyesight deafness have prevented her from working for a living and consequence of her privations her general health has suffer Owing to her increasing infirmities she will soon have to h someone to attend to her wants. Her income has recently b increased to £73 p.a. Fund Voted £26.

Subscriptions and donations should be sent to the Honor Treasurer, Sir Charters Symonds, at 11, Chandos-str Cavendish-square, London, W. 1.

"Audi alteram partem."

OUR HOSPITAL SYSTEM.

THE SILENT REVOLUTION.

To the Editor of THE LANCET.

SIR,—Since the year 1844 the poor-law system of this country has remained in much the same state. The fundamental principles then laid down the conditions necessary for the reasonable treatment of the poor; many and great changes have occurred during the past 80 years.

The working man, then included among the poor, has ceased to be regarded as one to whom assistance is to be given more or less regularly, year by year, out of the rates. He, indeed, was under exceptional circumstances entitled to the advantages conferred by those laws, but no longer is he in need of many of them. Further, by his own efforts he has secured a position in the country which commands the respect of all citizens, for he has made provision for himself during times of sickness, in the periods of unemployment, and in his old age. There remains, however, one direction in which he has not been able to secure what is to-day most desirable for him. That is institutional hospital treatment when sick or injured. Time was, and that not long since, when diseases, major as well as minor, could be and indeed were treated in the home, however inadequate the accommodation might be, and for such domiciliary treatment the working man has since the middle of the last century made more or less satisfactory provision. Such treatment of disease as he could manage to pay for and such accommodation as he could secure in his own house are to-day not only thought to be inadequate but known to be insufficient and far from what is desirable and what should be provided for him. The sailor and the soldier are provided for in a manner worthy of this great State; and our working men should be equally well provided for, not only in their own interests, but also in that of the economic interests of our many if not all industries.

No longer can it be contended that the cottage in the country or the small house in the town is a fit and proper place for the retention and the treatment of sick members of the working man's family. His house is small enough for those who dwell in it when the members are well, but it is totally unsuitable for the accommodation of any sick as well as the healthy members. It is in that direction that the next need of the working man presents itself. The accouchements of his wife require the healthiest and best of surroundings so that the mother may speedily recover and the child be properly attended to in the early days of its existence; and both he and every other member of his family, when sick, need a place where they can receive skilful attention and care in nursing with every medical service and requisite that may be necessary. In no way can such service be secured for him and his family except by the establishment of hospitals on a sufficiently large scale where the best possible treatment—medical, surgical, dental, and in all other accessory branches—are provided. That provision, if made on an ample scale, would crown the work that was started by the provident societies—a work so well conceived and carefully executed in the last century.

The big hospitals—infirmaries as they are called—grudgingly provided under the poor-law system and now about to be dissolved with that organisation, have partially supplied the needs of the large towns and cities. They, however, have never been developed by the medical profession in the manner they should have been and in one that the authorities have ever been sympathetic with. Soon these hospitals, some of the first order, will all come by transference under the government of the county councils, and the county councils may under the new conditions combine to create adequate hospital accommodation, not only for the treatment of fevers, tuberculosis, &c., but for ordinary medical and surgical diseases and for a maternity service that should come up to a standard worthy of this country and suitable to meet the needs of our people.

The union infirmaries are passing away; the infirm require new accommodation and the sick need ample provision for their treatment. The dissolution is at hand. Is the reconstruction in hand? I fear not, and my fear is based upon the well-known ultra-conservative nature of the medical profession. In 1844 the great doctor teachers in London were the means of preventing the construction of adequate hospitals for the people, and their excuse was that the voluntary rather than charity hospitals with medical schools attached would be interfered with and might well be ruined, and medical education with them. To-day there is the same conservative feeling expressed by a few who think they foresee that the voluntary hospitals, as they are called to-day, would be damaged and their chief excuse for endeavouring to obviate that result is that only such hospitals can command the services of the best physicians, surgeons, accoucheurs, dentists, &c., for in them alone lies the true incentive to do the best work. What folly! Is there no work, like that to be seen in the British voluntary hospital, to be also seen in France, Germany, Italy, and elsewhere? Of course there is, and there would be the proper incentive in this country in such hospitals as the county councils, singly or in combination, might establish, equip, and run.

By the furtherance of the development of such hospitals the medical profession stands, I believe, to gain, and such a degree of gain as it has never known before. The present voluntary hospitals are no longer called charity hospitals, and the charity subscriptions are here, there, and everywhere being rapidly replaced by weekly contributions from working men, the result of their provident instinct, if I may say so, to make provision to meet future needs. It should be recognised that the medical schools attached to these hospitals are, even to-day, totally inadequate to give the aspirants to the medical profession the technical training—not book education and laboratory technique, be it noted—every doctor should receive before he is certified as fit to undertake doctoring duties on his own. It is indubitable that inadequacy in clinical facilities could, under present conditions in the hospitals with medical schools attached, be in great part, if not wholly, done away with were the coming county council hospitals provided with an organisation of experienced teachers for the further clinical training of medical students who would be able to satisfy examiners that they possess adequate knowledge to profit thereby. Such hospitals could then become institutions supplementary to our great medical schools, and would provide adequate and more than adequate means for gaining proficiency in the practical work so necessary in the profession of medicine. Additional opportunities are a great need, even greater to-day than ever before, owing to the enormous accumulation of knowledge in every direction in subjects which form the basis of medicine. That knowledge, as doled out at present, takes considerable time to acquire, and there is, in consequence, less time available for the student to devote to the training in the practical work of investigating and treating diseases. Proficiency in the art and practice of medicine cannot be attained without repeated experiences, and opportunities for these should be available, at any rate for all the best pupils preparing for the higher branches of the profession.

I am, Sir, yours faithfully,

Cambridge, Jan. 23rd, 1929. JOSEPH GRIFFITHS.

HENRY HICKMAN MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—The committee has decided not to close this fund at the end of January as provisionally stated.

From a contributor in Canada we gather that there may be medical men abroad, and in the Colonies, who wish to send a donation to the fund, and who have not yet had time to reply. The number of contributors has so far been disappointing. Without anæsthesia, the great achievements of present-day surgery would be impossible. We ask for further support, not only to recognise Hickman officially for the first time, but to claim this pioneer work for an Englishman, and in so doing to stimulate original work in anæsthesia. The hon. treasurer of the fund is Mr. V. Warren Low, F.R.C.S., 76, Harley-street, W.

I am, Sir, yours faithfully,

CECIL HUGHES, M.B.,
Hon. Sec., Hickman
London, W., Jan. 28th, 1929. Memorial Committee.

PROF. FERNAND WIDAL.

To the Editor of THE LANCET.

SIR,—In the obituary notice in your last issue Fernand Widal is given the title of *Professeur agrégé*. This is an error. Widal was *Professeur titulaire*—and this is not at all the same thing. The appreciation of the original work of Prof. Widal which follows is also not very precise, and hardly gives a fair estimate of the work done by this physician. The precise facts are the following :—

In 1889, when he was assistant physician to the hospitals of Paris, Widal showed the importance of the streptococcus in the genesis of puerperal phlebitis. In the same year he demonstrated with Chantemesse the possibility of vaccinating animals against typhoid infection by using vaccines made of microbes killed through the medium of heat, giving thus the basis of the prophylactic and of therapeutic vaccination. On June 26th, 1896 (therefore some months before the publication of A. S. Grünbaum), Widal introduced the agglutination reaction for the diagnosis of typhoid fever, and the fact that the whole world knows this reaction as "Widal reaction," and that even the Germans call it "Gruber-Widal," demonstrates sufficiently the rôle of the French physician in the discovery of this valuable method.

The most important work of Widal is probably his work on nephritis. He first demonstrated the rôle of salt in the genesis of œdema, and although since then theories on œdema have changed and will change, the clinical fact of the rôle of salt-free diet will remain as a permanent acquisition of science. Pushing his work further, Widal succeeded to free nephritis from the exclusive, and sterile therapeutically, anatomopathological point of view, and introduced his famous conception and analysis of the physiopathological syndromes of nephritis, isolating principally the azotæmic type and showing the diagnostical and prognostical significance of the variations of urea nitrogen in the blood. In 1900, with Ravaut and Sicard, he introduced the method of cyto-diagnosis of the exudates. In 1907, with Abrami and Brulé, he made a series of important works on the hæmolytic jaundice. In 1913 he started his researches on anaphylaxis, which would have remained a laboratory phenomenon, or at all events would have been limited to serum disease if Widal had not thrown into this work his clear intuition and his experimental genius. It is well known that thanks to this work on anaphylaxis and that of the importance of the disturbance of the colloidal equilibrium in the blood, medicine has been transformed by a sort of renovation of the old humeral pathology of the Greeks, and the treatment of a great number of diseases has largely benefited by the anti-anaphylactic medication.

I can only indicate the principal researches of Widal, but, in fact, there is no branch of medicine which has not benefited by his work, and all those who have followed the medical movement of these last years cannot agree with the words of your collaborator that "Widal achieved a reputation for original research which perhaps he hardly merited." On the contrary, this reputation is amply justified by the great original work of Widal.

Fernand Widal was eminently a representative of the great clinicians of the Paris school. He was not only an original worker, but a brilliant diagnostician and a remarkable teacher. As a consultant he was known even in the remotest corners of the world, and when some years ago he travelled through South America, he was received with real royal honours. He had great clinical tact, and I have had the occasion to appreciate this quality in a very dark period of the history of Greece, when Widal had been called, too late unfortunately, at the sick-bed of the late King Alexander. As a teacher he had made of the medical clinic of Cochin Hospital a centre of study and work for physicians coming from all parts of the world.

The man was as great as the physician ; although covered with glory and honours, Member of the "Institut"—the highest French scientific honour—Great Cross of the Legion of Honour—the highest French civil honour—he kept to the last days of his life his simplicity and sympathetic disposition, ready to help anyone, great or small. He loved his calling ; he was a fervent but not a narrow patriot, and a valuable friend.

I am, Sir, yours faithfully,

A. P. CAWADIAS.
Wimpole-street, W., Jan. 29th, 1929.

ASTHMA RESEARCH.

To the Editor of THE LANCET.

SIR,—That anyone, least of all a psychologist, should have been able to read into my letter and link up my name with the word "pessimism" is so astonishing that lesser misunderstandings may be excused. I have many failings, but never before in all my life have I been called a pessimist.

Referring to that portion of my letter, which Dr. Millais Culpin takes as a text for his short sermon, my point is that the asthmatic is not a neurotic, nor does he suffer from nervous manifestations, nor, but for very exceptional cases, is he in need of that ample assistance Dr. Culpin and his fellow practitioners can doubtless afford to the true neuropath.

Neurotic tendencies were wrongly imputed to the asthmatic in the past by a profession which was totally ignorant of the main causes of asthma as now recognised. When the patient said that cats gave him asthma, he was disbelieved ; now, by means of the skin reactions, full justification of his statement is possible. Dr. Culpin seems anxious to know what degree of stigma I personally attach to the adjective "nervous." My answer is, a very great deal. If the number of neurotics in the world were doubled, the health of society at large and the peace of the individual at home would be very adversely affected ; if it were halved, the nation would be far happier. Therefore, the neurotic is not an element for good, and in so far as he fails to add his quota to the general happiness of the world, so far is he a nuisance, and so far do his nervous manifestations carry a stigma.

I made no attempt in my letter to include all the possible methods of curing asthma, but because I did not mention psychotherapy it does not follow that I am totally ignorant of that science. Nor is it impossible that some of us may arrive at useful conclusions by sympathetic questions and by lesser methods than by stirring up the deeper pools of memory with a long stick and grabbing the dead leaves as they come to the surface.

As my views on psychology cannot be of the least interest to anyone, I will close with an article of faith. In my opinion it is of far greater value to 99 asthmatics out of every 100 to know whether they are sensitive to feathers, if they can take aspirin, if their tonsils are healthy, and such like very material questions, than to undergo a course of psycho-analysis. I am, Sir, yours faithfully,

Jan. 28th, 1929. FRANK COKE.

THE TREATMENT OF HÆMORRHOIDS BY INJECTION.

To the Editor of THE LANCET.

SIR,—Dr. Whitcombe asks how it is possible for injection of hæmorrhoids to "deal with those cases, very common, in which there is a large protruding œdematous mass of rectal tissue, showing bleeding ulcerative piles higher up," and expresses the hope that Mr. Christopher Howard and I will try his method of galvano-puncture. Let me assure him that I am treating cases such as he describes almost daily, and that if he will do me the honour of reading my book he will discover details of the method I follow.

Dr. Whitcombe does not improve his case by misquoting what transpired at the joint meeting of the Proctological Subsection of the Royal Society of Medicine and of the American Proctological Society.[1] The late Mr. Græme Anderson gave his recurrence rate as *15 per cent.*; Dr. Jack Halton, of Florida, believed that *nine-tenths* of uncomplicated cases were cured; Mr. Perrin said that 50 per cent. were absolutely cured, and a little over 30 per cent. were "substantially cured, but complained of trivial symptoms"; Dr. Zobel (San Francisco) believed that a few were cured, but nearly all were relieved and, if recurrence took place patients were usually willing to submit themselves to further treatment. Only one of the speakers reported expressed himself strongly against the treatment. All were dealing with the old interstitial injections, and most of them were using 10 per cent. carbolic in glycerine and water, which I have repeatedly pointed out is, in my experience, too weak and more often ineffectual than the 20 per cent. solution which I used to employ.

When Dr. Whitcombe sums up this discussion by writing that "the general opinion was that the method was only of use in simple uncomplicated cases,and that recurrence followed in some 50 per cent." he is hardly giving a fair and accurate account of the opinions actually expressed. Nor does he refer to my own figures which have been published in my book and elsewhere.[2] I ascertained that three years and upwards after treatment 83·4 per cent. remained free from even trivial symptoms, and that of the remaining 16·6 per cent. a large proportion had such trifling inconveniences as "a sense of heat after defæcation," itching, &c. Whilst misrepresenting the opinions given at the meeting to which he refers, and whilst failing to mention my own figures, Dr. Whitcombe gives no information about the number of cases he has treated by his own method, his own percentages of successes and failures, nor his method of selecting cases. That he has, at any rate, some recurrences and failures I know, because several of his cases have afterwards drifted into my own hands—some immediately after treatment by Dr. Whitcombe and others at longer or shorter intervals.

In a recent paper on the treatment by galvano-puncture by Dr. Whitcombe[3] reference is made to a patient on whom he had to use the cautery on "about a dozen different occasions, but the prolapse gradually subsided, and in two months the patient had completely recovered." This means that by his method over twice as many treatments are required and relief is far less prompt than is the case when submucous injections are used. In the same article Dr. Whitcombe mentions an alarming list of complications after galvano-puncture, including three cases of *secondary* hæmorrhage, which Dr. Whitcombe assumes occurred because the patients must have been hæmophiliacs. Since I have used the *submucous* injection of 5 per cent. carbolic acid in oil I have had no case of secondary hæmorrhage or of sloughing and I have also eliminated the cases of severe pain, which occurred in a small percentage of cases treated by the interstitial injection of stronger solutions in glycerine.

In these circumstances Dr. Whitcombe must forgive me if I decline his invitation to give his method of galvano-puncture a trial—at any rate, until he has published his own figures as regards recurrences, frequency of complications, the average number of treatments necessary, and so on.

I am, Sir, yours faithfully,

ARTHUR S. MORLEY.

Upper Wimpole-street, Jan. 26th, 1929.

[3] Brit. Med. Jour., 1928, ii., 1035.

HEINE, THE STRANGE GUEST.

To the Editor of THE LANCET.

SIR,—While thanking you for your appreciative review of my book, may I be permitted to allude to one sentence, wherein the otherwise excellent compositor has, it would seem, omitted an all-important "not"? You say that my book "should lead many who can read German to enjoy the poet's gay and serious phases, his wit, his penetration, and his lovely literary gift." I was under the impression that my book is written in English; and, if so, the omitted word would come after "can." But one never knows. There was a very famous British general who, in the war, convened a number of his own and of French officers. The second part of his discourse he delivered in what he thought fairly decent French; and at the end of it a French colonel jumped to his feet and exclaimed that, as this was doubtless a very noteworthy pronouncement, it should be, without a moment's delay, translated into the French language. I am, Sir, yours faithfully,

Jan. 27th, 1929. HENRY BAERLEIN.

*** We regret the slip; the "not" was intended.—ED. L.

Obituary.

FRANK MORT, M.B. GLASG.

Dr. Frank Mort, who died on Jan. 22nd, after a few days' illness, had been for many years well known in Middlesbrough, first as a general practitioner and later as a cardiologist. A graduate of the University of Glasgow he qualified in 1895, and after several sea voyages settled in the North of England, soon gaining a high reputation among his patients and showing an unusual diagnostic skill. At first, apart from general medicine, he made a specialty of obstetrics and gynæcology, but the ultimate goal of his ambition was the study of electro-mechanics and the neuro-physiology of the heart. He qualified for work as a cardiologist by post-graduate study in London and Vienna, where he worked with Dr. Dressler and Dr. Rösler. At the time of his death he was preparing an address embodying some of the work which he had undertaken with so much enthusiasm and skill during the past few years. Many in Middlesbrough will feel that by Dr. Mort's death they have lost a friend and counsellor. He is described as a "true physician; kindly, humorous, painstaking to a degree," and at his funeral men and women were seen weeping in the streets.

JAMES MUNCE, L.R.C.P. EDIN.

MEMBERS of the medical profession in Ulster have learned with deep regret of the death, from pneumonia, on Jan. 20th, of Dr. James Munce, of Lisburn. Born in 1868, he was the son of the late Mr. Robert Munce, of Newtownards; he received his medical education at Queen's College, Belfast, and afterwards in Dublin and Edinburgh, taking the diplomas L.R.C.P. and L.R.C.S. in 1896. As a student he was a well-known lacrosse player and played for the famous Ards Club. He became medical officer of Druinbeg Dispensary in 1900, and continued in this office until his death, gaining the confidence and affection of a very wide circle of patients and friends; he was a sound physician

and a particularly reliable anæsthetist, serving the County Antrim Infirmary in this capacity for 25 years. Not the type of man to seek popularity, few gained it more easily, and he was trusted by his medical colleagues.

Dr. Munce married Elizabeth Campbell, daughter of the late Mr. N. Perry, of Saintfield, and she survives him.

JOHN WATSON SIMPSON, M.B. EDIN., D.P.H.

AFTER a period of poor health Dr. Watson Simpson died at Birmingham on Jan. 11th at the age of 38, his early death being attributed partly to the effects of war service. An Edinburgh man, he represented the University at Rugby football, and but for an accident would have been chosen to play for Scotland. Graduating in 1915, he served in Egypt and Palestine, where he was badly gassed, and by this and other illness his constitution was so seriously affected that for the future he could not take part in athletics. In 1922, after taking the D.P.H., he secured the appointment of assistant medical officer for the county of Warwick, and was later given charge of the venereal diseases department of the Hospital of St. Cross at Rugby. School inspection occupied much of his time and interest, and in this connexion he won the respect and liking of both teachers and parents. Dr. Simpson leaves a widow and three children.

VICTOR GUSTAVE PLARR.

LIBRARIAN OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE much regret to announce the death of Mr. Victor Gustave Plarr, who has been Librarian at the Royal College of Surgeons of England for over 30 years, which occurred on Monday last, Jan. 27th, at his house in Wimbledon, in the sixty-sixth year of his age.

Victor Plarr was the son of an Alsatian savant and mathematician and was born near Strasbourg on June 21st, 1863, his mother being the daughter of a Lombard-street banker. The father, whose house was burnt in the Franco-German War, came to Scotland when his son Victor was 7 years of age, and became a naturalised British subject, while the son received his education at St. Andrews, and later at Tonbridge School, where he was a Judd exhibitioner. From school he proceeded to Worcester College, Oxford, and in 1886 graduated with honours in the Modern History school.

The whole of Victor Plarr's life was devoted to letters. He had many contemporaries at Oxford, who, out of inclination, necessity, or both, made literature their profession, and Plarr as a young man was a member of a group of free-lance writers and became the author of a good deal of verse, some interesting essays, and translations from the Greek and from the French, which was for him a second language. He was made editor of a valuable compilation, "Men and Women of the Time," a predecessor of "Who's Who," and in 1890 was appointed librarian at King's College, London. This post he held for seven years, when he took the post at the Royal College of Surgeons, in connexion with which his name is known to every member of the medical profession who has had need of expert assistance in the literature of the profession. He is responsible for about half of the now completed catalogue of the books in the College library, and for a complete catalogue of the manuscripts. A projected compendium of the lives of the Fellows of the College he completed in manuscript, bringing the biographical records up to 1922. He was a valued editorial contributor to our columns for a quarter of a century.

Plarr's kindly though cynical wit, wide range of literary and artistic accomplishment—for he was a good pastellist—tolerance of honest effort, and contempt for pretentiousness, made of him a delightful and stimulating companion, and his death will be regretted by a large circle of friends in private life, in official circles, and at the Athenæum.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Vice Admiral Arthur Gaskell, C.B., O.B.E., Medical Director-General, has been appointed an Honorary Surgeon to the King.

Surg. Lt. (D.) C. Williams to be Surg. Lt.-Comdr. (D.).

D. F. Walsh to be Surg.-Lt.

The following appointments have been made: Surg. Comdr. G. R. McCowen to *President*, for post-graduate course.

Surg. Lt. E. H. Rampling to *Victory*, for R.N. Barracks, Portsmouth, temp.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub.-Lieut. E. H. Parkinson to be Surg. Sub.-Lieut.

The following appointment has been made: Surg. Lt. H. O'Connor to *Victory*, for R.N. Hospl., Haslar, for training.

ROYAL ARMY MEDICAL CORPS.

Maj. B. H. H. Neven-Spence, Reg. Army Res. of Off., relinquishes his appt. under Art. 507 (b), Royal Warrant for Pay and Promotion, 1926.

Capts. J. R. S. Mackay (Prov.) and A. K. Robb to be Majs.

Capt. W. I. F. Powell from the Sudan Def. Force to the Egyptian Army and remains secd.

TERRITORIAL ARMY.

Maj. W. Campbell, R.A.M.C., to be Divl. Adjt., 51st (Highland) Div., T.A., vice Maj. F. C. Chandler, R.A.M.C., who vacates the appt.

Capt. W. Y. Eccott, R.A.M.C., to be Divl. Adjt., 48th (S. Mid.) Div., T.A., vice Maj. J. H. Fletcher, R.A.M.C., who vacates the appt.

Capt. E. J. S. Bonnett, R.A.M.C., to be Divl. Adjt., 49th (W. Rid.) Div., T.A., vice Maj. H. A. Sandiford, R.A.M.C., who vacates the appt.

Lt. A. Angus to be Capt.

ARMY DENTAL CORPS.

E. C. Irish to be Lt. (on prob.).

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. R. B. Purves, having attained the age limit retires, and retains his rank, with permission to wear the prescribed uniform.

Maj. J. H. Thompson, having attained the age limit, relinquishes his commn. and retains his rank.

ROYAL AIR FORCE.

Squadron Leader J. C. Osburne is placed on the retired list on account of ill-health.

Flight Lt. E. G. Howell is transferred to the Reserve, Class Dii.

INDIAN MEDICAL SERVICE.

Capt. J. S. Galvin to be Maj.

Lt.-Col. W. R. Battye retires.

A MEDICAL TOUR TO THE POLAR CIRCLE.—In response to a wish expressed by previous participants in the tours which are annually organised by the journal *Bruxelles-Médical*, the next tour will visit the Polar Circle, and will last 24 days. The itinerary will allow the paying of visits to some of the prettiest fjords in Norway, the Lofoten, the Faroe, and the Shetland Islands, and will end with the Firth of Forth and Edinburgh. The *Brazza*, "*paquebot de luxe*," will start from Bordeaux, but the trip commences at Zeebrugge on July 13th. The following fjords will then be visited: Norheimsund, Bergen, Gudvangen, Balhom, Loe, Merok, and Andaelsnaes by July 23rd, Svartisen and the Polar Circle being reached two days later. The *Brazza* will then visit Digermulen and Thorshavn and the Shetland Islands, Edinburgh being arrived at by July 31st. The trip will terminate where it began on August 4th. Anyone can join the *Brazza* at Bordeaux on payment of a small addition to the price of the fares, which are quite moderate—indeed one-third lower than the usual price charged for similar tours. Two classes are provided, and the whole tour for medical passengers will cost from 2500 fr. to 5375 fr., according to the class occupied. These prices are specially made for doctors, their wives, and unmarried children.

Medical News.

UNIVERSITY OF LONDON.—At a meeting on Jan. 23rd the Senate accepted, with thanks, an offer of the committee of the Bayliss-Starling Memorial Fund of the sum of £2500 for the establishment at University College of a scholarship for training in physiology and biochemistry to commemorate the connexion with physiology of Sir William Bayliss and Dr. E. H. Starling, formerly professors at that College.

It was resolved to institute an Academic Diploma in Clinical Pathology.

The degree of D.Sc. in Anatomy was conferred on Dr. H. A. Harris, assistant professor of anatomy at University College, for a thesis in the form of a series of memoirs dealing with the problems of bone growth, radiology, and teratology.

Mr. A. Sterling Parkes, D.Sc., was awarded the William Julius Mickle Fellowship for 1929, in respect of the work he has carried out during the past five years on the physiology and biochemistry of the organs of reproduction.

A report was received from the committee appointed by the Senate to inquire into the medical education of women (see p. 251).

UNIVERSITY OF LIVERPOOL.—A Fellowship in the Faculty of Medicine for research in tuberculosis in children has been endowed by the gift of £2000 by the trustees of the late Mrs. Ridgway.

UNIVERSITY OF MANCHESTER.—With the concurrence of the board of management of the Manchester Royal Infirmary the council has appointed Dr. J. F. Wilkinson to be director of the Laboratory of Clinical Investigations. Dr. Jethro Gough has been appointed Demonstrator in Pathology.

COLLEGE OF PESTOLOGY.—At a luncheon to be given on Feb. 20th at the Hotel Cecil, London, Mr. A. Moore Hogarth, chairman of the college, will receive a presentation of his portrait in oils. The presentation will be made by Sir James Crichton-Browne, F.R.S., the first president of the college.

GERMAN BALNEOLOGICAL SOCIETY.—At the jubilee congress of the Deutsche Balneologische Gesellschaft lately held in Berlin, Dr. R. Fortescue Fox was elected an honorary member of the society. The French Ministry of Health was represented at the meeting by Dr. Frenkel, and the Société d'Hydrologie Médicale by Dr. Macé de Lépinay and Dr. Glénard.

OLIVER STUDENTSHIP IN BOTANY.—After 40 years' service as Quain Professor of Botany, University College, London, Prof. F. W. Oliver will retire from this post at the end of the present session. Prof. Oliver succeeded his father, so that the chair of botany has been filled by father and son for 68 years. A special effort is being made to raise a permanent memorial associated with their name, and to this end a committee of his past and present colleagues and students has been formed. The scheme is to found a Studentship in Botany open to post-graduate students of the University of London, and in addition, to make a personal gift. Contributions to this fund should be sent to Dr. Paul Haas, at University College, Gower-street, W.C.

JOINT TUBERCULOSIS COUNCIL.—At a meeting of the Council held on Jan. 19th, Sir Henry Gauvain was elected chairman for 1929; Dr. G. Lissant Cox, vice-chairman; Dr. Ernest Ward, hon. secretary; and Dr. James Watt, hon. treasurer. A report on behalf of the employment committee was presented by Dr. J. B. McDougall, and in the discussion which followed Dr. Varrier-Jones emphasised the importance in colony work of providing opportunities to those of them who showed exceptional ability to rise to the position of supervisors and teachers. The committee was asked to report on after-care, including employment schemes and the employment of ex-patients in residential institutions. Dr. Lissant Cox's valuable memorandum on the "Fate of Young Children in Tuberculous Households" was further discussed. Concerning post-graduate study, Dr. W. Brand reported that during 1928, 14 had attended the course at Alton, 18 at Papworth, and 30 at Victoria Park Hospital. For 1929 he proposed more than one course in surgical tuberculosis, a course in artificial pneumothorax therapy and the interpretation of radiograms, and a course at the University of Paris during Easter.

STAMFORD INFIRMARY.—With the exception of a wing recently erected, this hospital is to be converted partly into a nurses' home and partly into staff quarters, and a new block is to be put up containing 44 general and six private beds. The cost will be £17,000.

EAST LONDON HOSPITAL FOR CHILDREN.—There will be a clinical afternoon at this hospital at Shadwell at 4 P.M. on Wednesday, Feb. 6th. Some Blood and Skin Diseases will be the subject. Medical practitioners are invited, and tea will be served at 3.45 P.M.

A "STAFF FUND."—The North Walsham and Gimingham Sunday and Saturday Hospital Fund has given £40 to the North Walsham and District Hospital as the nucleus of a "staff fund" from which to pay the out-of-pocket expenses of consultants called in from a distance, and others who give unpaid services.

INTERNATIONAL SOCIETY OF EXPERIMENTAL PHONETICS.—The first annual Conference Week of this society will be held in Hamburg from July 24th to 31st. Membership of the society is open to all persons, institutions, libraries, and corporations (commercial and otherwise) who are interested in the subject. Communications should be addressed to the President, Prof. E. W. Scripture, Strudelhofgasse 4, Vienna, or 25, Howard-road, Coulsdon, Surrey.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.—This Board announces that an examination for nine medical scholarships and exhibitions, of an aggregate total value of £1170, will commence on April 16th. They are tenable at University College and University College Hospital Medical School, King's College and King's College Hospital Medical School, and the London (Royal Free Hospital) School of Medicine for Women. Full particulars and entry form may be obtained from the Secretary of the Board, Mr. S. C. Ranner, the Medical School, King's College Hospital, Denmark-hill, S.E. 5.

SWINEY PRIZE FOR JURISPRUDENCE.—The Swiney prize for 1929 has been awarded by the adjudicators, the Royal Society of Arts and the Royal College of Physicians, to Dr. Sydney Smith, Regius Professor of Forensic Medicine in the University of Edinburgh, for his work, "Forensic Medicine." Dr. Swiney, who died in 1844, left a sum of money to the Royal Society of Arts to provide a prize every fifth year for the best published work on jurisprudence. The prize, which consists of £100 and a silver cup of the same value, was offered this year on the 85th anniversary of the testator's death for a work on medical jurisprudence.

THE QUEEN AT MIDDLESEX HOSPITAL.—On Thursday in last week the Queen laid the foundation-stone of the new Nurses' Home of the Middlesex Hospital in Foley-street, W. An anonymous benefactor has given £200,000 towards the cost of erecting the building, which will accommodate 450 sisters, nurses, and maids, and will contain rooms for teaching purposes. Every bedroom will have hot and cold "running water," wireless will be installed in the recreation rooms, and there will be a Badminton court on the roof. A sealed envelope containing the benefactor's name was placed within the foundation stone.

PRESENTATION TO A MEDICAL MAN.—Dr. Percy Coleman, of Clacton-on-Sea, who for 30 years has been connected with the Clacton and District Hospital, has been presented with his portrait in oils, an album containing the names of the 335 subscribers, and a wallet containing the residue of the fund. The presentation was made at a largely attended meeting at the Grand Hotel, Clacton, presided over by Brigadier-General K. J. Kincaid-Smith, and attended by the medical practitioners and well-known people of the town. During the evening many tributes were paid to Dr. Coleman's work both for the hospital and in the town, and Mrs. Coleman was presented with a basket of flowers. The portrait is the work of Mr. Harold Knight, A.R.A.

MEDIÆVAL TOWNS AND SPAS OF GERMANY.—A Whitsuntide round of visits to certain well-known mediæval towns and medical spas of Germany is being organised by Mr. Henry Baerlein, who has already arranged successfully for the visit of mixed parties of medical and lay men and women to Jugoslavia and Czecho-Slovakia. The tour, which will start on Tuesday, May 14th, will last 21 days, and a detailed itinerary will be published later in these columns. Among the places visited will be Hildesheim, Brunswick, Goslar, the Brocken, Weimar, Kissingen, Nuremburg, Rotenburg, Wurzburg, Heidelberg, Frankfort and Bad Nauheim, Homburg, Wiesbaden, and Cologne. Already Mr. Baerlein can supply much detailed information, and he will do so in reply to communications addressed to him at the Bath Club, 34, Dover-street, London, W. 1.

Dr. P. S. SELWYN-CLARKE, *M.C.*, of the West African Medical Staff, was called to the Bar at Gray's Inn on Jan. 28th.

ULSTER MEDICAL SOCIETY.—At a meeting of this society at Belfast on Jan. 24th, Mr. Harry Platt (Manchester) read a paper on Some Tendon and Muscle Ruptures. In the course of his address he pointed out that what is usually diagnosed as rupture of the plantaris tendon is almost always rupture of the gastrocnemius muscle, the correct early treatment being compression by strapping or bandage, limited exercise, and early massage; that injuries to the short head of the biceps are not uncommon in young subjects—e.g., footballers—and that the symptoms are frequently obscure for 48 hours; that insidious rupture of tendons by osseous change—e.g., in arthritis—or by tenosynovitis may occur, notably in the tendon of the extensor longus pollicis (the kettle-drummer's paralysis of German authors). He described his operation for the cure of this condition by the construction of a pulley and a new site for the tendon, illustrating this by lantern-slides.

DONATIONS AND BEQUESTS.—Miss Charlotte Elizabeth Peck, of Cecil-road, Preston, Birkenhead, left £21,766, and, subject to various private bequests, the residue of the estate is left in two parts each to Birkenhead Borough Hospital; Birkenhead and Wirral Children's Hospital; Liverpool Open Air Hospital for Children, Leasowe; Birkenhead and Wirral Society for the Prevention of Cruelty to Children; and the Shaftesbury Boys' Club, Birkenhead.—Mr. Hugh Mitchell, J.P., F.S.A., of Dundarach, Pitlochry, Perthshire, solicitor, left £5000 to the Irvine Memorial Nursing Home for Atholl, and £100 to Edinburgh Royal Infirmary.—Sir John Phillips, M.D., F.R.C.P., of St. John's Wood, London, N.W., and late of Talbot-square, Hyde Park, W., honorary physician to the Queen, and obstetric physician to King's College, London, left £1000 to King's College Hospital, to found and endow a bed in the obstetric ward in memory of his wife.—Alderman John Frater, of Alma Place, North Shields, left £2000 to Tynemouth Victoria Jubilee Infirmary, £1000 to Tynemouth Blind Welfare Society and the Northern Counties Library, North Shields, and £1000 in trust to pay the fees of not more than 12 married women's maternity cases in the Frater Maternity Home.—The London Lock Hospital has received £5928 13*s.* 10*d.* from the executor of the late Mr. J. H. J. Hornsby's bequest, and donations of £1150 from the residuary legatees of the late Miss Drake-Beer.—Mr. F. Stirling Newall, of Wylam-on-Tyne, has sent a cheque of £10,000 to Lord Armstrong, Chairman of the Royal Victoria Infirmary, Newcastle-on-Tyne, Appeal Fund.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 5th.—5 P.M., ORTHOPÆDICS. Cases will be shown by Mr. Laming Evans: Case of Madelung's Deformity. Mr. Alan Todd: Bilateral Coxitis after Measles; Radiograms of a Case of Köhler's Disease of the Second Metatarsal; Milroy's Disease. Mr. W. H. Ogilvie: Radiograms of a Case of Kienboch's Disease and Keilts Disease. Other cases will be shown. 8 P.M., PATHOLOGY. Laboratory Meeting at the Lister Institute, Chelsea Gardens, S.W.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Mr. C. J. S. Thompson will show a photograph of an unknown portrait of Ambroise Paré. Paper: Mr. H. W. Carson: The Iliac Passion. Members are invited to bring objects (books, prints, documents, instruments, medals, &c.) of historical interest for exhibition at the meetings of this Section. 8.30 P.M., WAR and SURGERY. Special Discussion on the Necessity for Early Diagnosis in the Treatment of Spinal Injuries. Openers: Group-Captain H. V. Wells (War), Sir Percy Sargent (Surgery). N.B.—There will be no meeting of the War Section on Feb. 11th.

THURSDAY.—8.15 P.M., TROPICAL DISEASES. Subject: Monkeys and Human Disease. Short Papers by Mr. R. I. Pocock: Zoological Relationships of Primates (Apes and Monkeys). Mr. R. Lovell: Bacterial Diseases. Mr. E. Hindle: Virus Diseases. Dr. J. G. Thomson: Protozoal Diseases. Mr. T. W. M. Cameron: Helminthic Diseases. Dr. V. B. Wigglesworth: Insect Diseases. Colonel A. E. Hamerton: Morbid Anatomy. A Discussion will follow. COMPARATIVE MEDICINE: Members of this Section are specially invited to attend this meeting.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.). Cases: Dr. C. Worster-Drought: Case of Syringomyelic Arthropathy of Both Wrists. Dr. Bernard Myers: Two Cases of Essential Thrombocytopenic Purpura Hæmorrhagica, Three Years after Splenectomy. Dr. Hugh S. Stannus: Case of Hysterical Gait Following Encephalitis. Dr. Norman Hill: Case of Severe Rickets. Dr. Terence East: Case of Multiple Lipomata. Dr. J. B. Alexander: Case of Pyrexia of Obscure Origin. Mr. Cecil P. G. Wakeley: Case of Mixed Tumour of the Palate; Two Cases of Bilateral Parotid Swellings; Case of Bone Graft for Osteomyelitis of the Tibia. Dr. L. S. T. Burrell: Case of Pulmonary Tuberculosis with Tuberculous Tongue. Other cases will be shown. 8.30 P.M., OPHTHALMOLOGY. (Cases at 8 P.M.) Clinical Cases: Mr. A. Griffith: Charts of Fields of a Case of Pituitary Tumour Treated by X Rays. Other cases will be shown. Papers: Mr. R. Foster Moore and Mr. Scott: Clinical and Pathological Report of Bilateral Glioma Retinæ. Mr. R. Foster Moore: Cirsoid Aneurysm of the Visual Cortex. Mr. Basil Graves: Scleral Illumination.

ROYAL INSTITUTION, Albemarle-street, W.

WEDNESDAY, Feb. 6th.—5.15 P.M., Prof. J. S. Huxley: Evolution and the Problem of Species.

THURSDAY.—5.15 P.M., Sir William Bragg: The Early History of X Rays.

BIOCHEMICAL SOCIETY.

MONDAY, Feb. 4th.—5 P.M. (Demonstrations at 3.30 P.M.), in the Lister Institute, Chelsea Bridge-road, S.W. Communications: H. Chick and M. H. Roscoe: (*a*) Methods for the Assay of Vitamins B_1 and B_2; (*b*) On the Separation of Vitamins B_1 and B_2 from Yeast. M. H. Roscoe: Rats Reared Eight Months After Weaning on Diets Deprived of B Vitamins. T. Lumsden (introduced by C. J. Martin): The Effect of Various Reagents upon Cells Cultured in vitro. L. F. Hewitt: Hormones of the Anterior Pituitary Lobe. N. F. Maclagan (introduced by E. C. Dodds): The Use of Decinormal Hydrochloric Acid for Standardising Electrometric pH Measurements. E. Boyland: The Sequence of the Formation of Phosphoric Esters and Carbon Dioxide in Fermentation by Dried Yeast. R. Robison and E. King: Hexosemonophosphoric Ester. E. King and W. T. J. Morgan: Methylated Derivatives of Hexosemonophosphoric Ester. W. T. J. Morgan: The Constitution of Hexosediphosphoric Ester. Demonstrations: G. H. Eagles (introduced by J. C. G. Ledingham): Growth of Vaccine Virus in Tissue Culture. A. Felix (introduced by J. C. G. Ledingham): Floccular and Granular Agglutination Phenomena. T. Lumsden and A. C. Kohn-Speyer (introduced by C. J. Martin): Serum as a Culture Medium for Serological and other Tests. E. M. Hume, N. S. Lucas, and H. Henderson Smith: Three Common Marmosets (*Hapale jacchus* Linn.) Bred in Captivity with the Aid of Ultra-violet Irradiation.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn, W.C. (Hunterian Lectures.)

MONDAY, Feb. 4th.—5 P.M., Prof. R. J. McN. Love.

WEDNESDAY.—5 P.M., Prof. C. P. G. Wakeley.

FRIDAY.—5 P.M., Prof. R. T. Payne.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 4th, to SATURDAY, Feb. 9th.—MEDICAL SOCIETY, 11, Chandos-street, Cavendish-square, W. Lecture by Sir Henry Simson on Some Obstetric Pitfalls, on Mon., at 5 P.M.—QUEEN MARY'S HOSPITAL, Stratford, E. Demonstration in General Surgery by Mr. A. E. Mortimer Woolf, on Mon., at 2 P.M.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Demonstration on Rheumatism and the Cardiac Child by Dr. Gerald Slot, on Tues., at 2 P.M.—WELLCOME MUSEUM OF MEDICAL SCIENCE, 33, Gordon-street, W.C. Demonstration on Tumours of the Thyroid Gland and Their Treatment by Mr. A. E. Mortimer Woolf, on Wed., at 4 P.M. The above are free.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Feb. 4th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.

FRIDAY, Feb. 1st.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Feb. 4th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Mr. Williamson Noble: Optic Atrophy.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Critchley: Reflex Epilepsy.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Complications of Disease of the Cranial Air Sinuses.

FRIDAY.—12 noon. Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educational Methods.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Feb. 8th.—4 P.M., Mr. J. D. McLaggan: The Treatment of Chronic Suppurative Middle Ear.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Feb. 7th.—4 P.M., Mr. Pitts: Dental Sepsis.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Feb. 5th.—5 P.M., Dr. S. E. Dore: Alopecia.
THURSDAY.—5 P.M., Dr. A. M. H. Gray: Xanthoma, Herpes.

UNIVERSITY COLLEGE, London.
TUESDAY, Feb. 5th.—5.30 P.M., Miss Julia Bell (Galton Research Fellow): The Handicapping of Men by Diseases Transmitted by, but not Developing in, Women.

ST. MARY'S HOSPITALS POST-GRADUATE LECTURE, Manchester.
FRIDAY, Feb. 8th.—4.30 P.M. (at the Whitworth-street West Branch), Dr. Bride: Toxæmias of Pregnancy.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Feb. 8th.—3.30 P.M., Dr. Nash: Clinical Cases.

Appointments.

ABEL, A. LAWRENCE, M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Cancer Hospital.
CROWDEN, G. P., M.Sc., L.R.C.P. Lond., M.R.C.S., Lecturer in Applied Physiology in the Division of Public Health at the London School of Hygiene and Tropical Medicine.
STOCK, STUART V., M.B., B.S. Lond., M.B., B.Ch. Bristol, Honorary Anæsthetist, Bristol Royal Infirmary.
STOESSIGER, HILDA N., M.D. Lond., M.R.C.P. Lond., Assistant Physician, Princess Louise Kensington Hospital for Children.
TIBBLES, SYDNEY, L.R.C.P., L.R.C.S. Edin., F.R.F.P.S. Glasg., Honorary Oculist to the Musicians' Benevolent Fund.
WILKIE, J., M.B., Ch.B. Glasg., D.P.H., Resident Medical Officer of the Hull Infectious Diseases Hospitals.
Westminster Hospital: MORGAN, T. W., L.R.C.P. Lond., M.R.C.S., Senior Resident and Casualty Officer; WALLER, R. S. L., L.R.C.P. Lond., M.R.C.S., and MINDLINE, J., L.R.C.P. Lond., M.R.C.S., Resident House Physicians; LLOYD, O. P., L.R.C.P. Lond., M.R.C.S., and MACHRAY, R., L.R.C.P. Lond., M.R.C.S., Resident House Surgeons; and WILLIAMS, A. W., L.R.C.P. Lond., M.R.C.S., Obstetric Assistant and House Physician to the Children's Department.
Certifying Surgeons under the Factory and Workshop Acts: MAGUIRE, W. H., M.B., B.Ch. Dub. (Roade District of the County of Northampton); and GELL, G. C., L.R.C.P. Lond., M.R.C.S. (Staveley District of the County of Derby).

Vacancies.

For further information refer to the advertisement columns.

Birmingham Royal Cripples Hospital.—Sen. H.S. £400.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.
Bootle Borough Hospital, Derby-road.—Sen. M.O. Also Two Jun. M.O.s. At rate of £150 and £125 respectively.
Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £100.
Bristol, Brentry Certified Institution, Westbury-on-Trym.—Res. Med. Supt. £650.
Cancer Hospital, Fulham-road.—Director of Electrical and Radio-Therapeutic Dept.
Carlisle City.—School Dentist. £500.
Charing Cross Hospital, W.C.—Hon. Clin. Asst. in X Ray Dept.
Derby, Derbyshire Royal Infirmary.—Asst. H.S. and Cas. O. At rate of £150.
Dreadnought Hospital, Greenwich.—Physician to Out-patients.
Durham County Council, Education Department.—Asst. School M.O. £600.
East Ham Memorial Hospital, Shrewsbury-road, E.—Hon. Asst. Physician.
Folkestone Borough.—M.O.H. £900.
Glasgow Royal Cancer Hospital.—Medical Officer. £600.
Gloucester County Mental Hospital.—Jun. Asst. M.O. £350.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. in the Dept. of Pathology. £350.
Hospital for Sick Children, Gt. Ormond-street, W.C.—Cas. O. £400. Also Asthma Research Scholar. £300.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Asst. Surgeon.
Ilford Emergency Hospital.—Jun. H.S. £100.
Ipswich County Borough.—Asst. M.O.H., &c. £600.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150. Also two H.S.'s. Each at rate of £120.
Jersey Mental Hospital.—Med. Supt. £650.
Lucknow University.—Professorship of Medicine and Physician to King George's Hospital. Rs.1200–50–1400 p.m.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. Also H.S. to Ear, Nose and Throat Dept. Each at rate of £200.
Manchester, Ancoats Hospital.—H.P. At rate of £100.
Manchester Hospital for Consumption, &c.—Hon. Asst. Phys.
Manchester Royal Eye Hospital.—Two Jun. H.S.'s. Each £120.
Manchester, Royal Infirmary.—Anæsthetist. At rate of £50.
Melbourne University, Victoria, Australia.—Chair of Obstetrics. £2000.
Middlesex Hospital Medical School, W.—Radium Registrar. £300.
Park Royal Hospital, Acton-lane, Willesden.—Res. First Asst. M.O. £430.
Preston Union.—Jun. Res. M.O. At rate of £104.
Royal Free Hospital, Gray's Inn-road, W.C.—Eastman Dental Clinic Director.
Smethwick County Borough.—Sen. Asst. M.O.H. £550.
Southern Rhodesia Government, Public Health Department.—Medical Inspector of Schools. £800.
St. Andrew's Hospital, Dollis Hill, N.W.—Asst. Surgeon.
Stafford, County Mental Hospital.—Second Asst. M.O. £600.
Sutton, Surrey, Downs Hospital for Children.—Jun. Asst. M.O. £500.
Swansea County Borough Infectious Diseases Hospital.—Res. M.O. £350.
Swansea Hospital.—H.S. £150.
Warwick County Mental Hospital, Hatton.—Jun. Asst. M.O. £350.
Watford, Herts, Peace Memorial Hospital.—Res. M.O. At rate of £150.
Warwickshire County Council.—Asst. County M.O.H. £600.
West Bromwich and District General Hospital.—H.S., H.P. Also Cas. H.S. Each at rate of £200.
West London Hospital, Hammersmith-road, W.—Hon. Obstetric Registrar.
Willesden General Hospital, Harlesden-road, N.W.—Hon. Ophthalmic Surgeon.
Wolverhampton, Royal Hospital.—Res. M.O.
Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—Hon. Sen. Dental Surg., Hon. Dental Surg. Also Asst. Phys. to the Radiological Dept. £50.
York, The Retreat.—Jun. M.O. £300.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Higham Ferrers (Northants), Barrow (Lancs.), Bucksburn (Aberdeenshire), Harrold (Beds.)

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for Banff County (Sheriffdom of Aberdeen, Kincardine, and Banff). Applications should reach the Private Secretary, Scottish Office, Whitehall, London, S.W., not later than Feb. 16th.

Births, Marriages, and Deaths.

BIRTHS.

PARKINSON.—On Jan. 26th, at Devonshire-place, W., the wife of Dr. John Parkinson, of a daughter.

DEATHS.

ADDENBROOKE.—On Jan. 22nd, at Consterdyne, Kidderminster, Bertram Addenbrooke, M.D., aged 54 years.
BARKER.—On Jan. 22nd, at Wandsworth Bridge-road, S.W., William James Townsend Barker, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., D.P.H., aged 68 years.
BULTEEL.—On Jan. 17th, Samuel Bellenden James Bulteel, M.B., C.M. Edin., of Beverley, Cary-avenue, Babbacombe, S. Devon.
GREENWOOD.—On Jan. 23rd, at Hemingford Abbots, Hunts, Arthur Greenwood, M.R.C.S., L.R.C.P. (late of Highgate), aged 77 years.
JAMES.—On Jan. 22nd, at his residence, De Cham-road, St. Leonards-on-Sea, Major Henry Daniel James, R.A.M.C. (retired), aged 71 years.
JONES.—Watkin Williams Jones, 9, Kempshott-road, Streatham Common, S.W.16, M.D. Brux., 1876; F.R.F.P.S. Glas., 1876; L.S.A. Lond., 1869 (Char. Cross); late Hon. Phys. C.E.T.S. Home for Inebriates, Whatlington; Surg. J.P. and Coroner, Colon, Serv.: Surg. and Insp. P. & O.S.N. Co. Sub. Editor of THE LANCET, 1870-76.
MCDERMOTT.—On Jan. 22nd, at Lypiatt-terrace, Cheltenham, Lieut.-Colonel Thomas McDermott, O.B.E., R.A.M.C. (retired).
PERRY.—On Jan. 21st, Edward Verdon Perry, O.B.E., M.R.C.S., of Reepham, Norfolk, in his 77th year.
TIGHE.—On Jan. 21st, at Stannington, Northumberland, Lieut.-Colonel John Valerian George Brosnan Tighe, M.B., Superintendent of Gateshead Mental Hospital.
WIGGLESWORTH.—On Jan. 23rd, at Oak-road, Withington, of pneumonia, after a very short illness, Winefred Furnival Wigglesworth, M.B., D.P.H.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. II., 1928.

THE Index and Title-page to Vol. II., 1928, which was completed with the issue of Dec. 29th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

MEDICINAL WATERS OF SOUTH AFRICA.

UNDER the auspices of the International Society of Medical Hydrology, a small meeting of hydrologists and chemists took place on Jan. 24th, when Mr. M. Rindl, professor of chemistry at Grey University College, Bloemfontein, gave an account of the chemistry of certain South African waters. The High Commissioners for South Africa and New Zealand were represented at the meeting. Prof. Rindl stated that he had been drawn to the subject in the search for home supplies of potash, and though his survey of the springs had failed to provide any results in that direction, he had made and published a preliminary survey, in the hope of arousing medical and other interest in this important national asset. He found that the analyses of the waters were often incomplete and out of date, that insufficient clinical data were forthcoming, and that bathing facilities were inadequate. Many of the springs had a long history of use, first by the aborigines, and then by the farmer-settlers, some still being used only in the most primitive way. Yet the waters themselves were well worthy of study and development. They were principally either sulphurous or chalybeate, no important brine springs being known, in spite of the extent of the surface "salt-pans." Seven of the springs had temperatures exceeding 105° F., the hottest being 158° F. Many were said to be radio-active, and one had a fair proportion of helium. In the discussion that followed, Dr. Arthur Herbert spoke of his experience in the development of the spas of New Zealand, under the Government Department of Tourist and Health Resorts. Government action was essential in new and sparsely populated countries. Where abundant thermal waters were present in a good climate, it was a mistake, he said, to build elaborate baths. What was needed was to concentrate on accommodation for patients, and the provision of medical attention and auxiliary treatment. Dr. A. Cawadias emphasised the supreme necessity of obtaining clinical data before full development could take place. Other speakers included Dr. Fortescue Fox, Dr. E. P. Poulton, Mr. Judd Lewis, and Dr. Brittan Gill.

SANDOW'S SYMMETRION ROLLER.

Sandow's Symmetrion Roller is a mechanical appliance for the application of self-massage which can be used easily over any area of the body where such treatment is required. It consists of five rollers of a soft spongy material arranged on a central axis with handles at either end, the length of the apparatus being just short of 2 feet. From the handles there run elastic cords, playing through pulleys which themselves are hooked on to a bent rod for fixation to any hook or staple placed at the appropriate height. The rollers give a yielding pressure and will adapt themselves accurately to inequalities of surface on the part being massaged, while the elastic tension of the cords permit of the necessary pressure being applied and regulated while the body is in a state of muscular relaxation. The movements can be carried out either when the patient is in an upright position or reclining, and the more there is relaxation during massage the more beneficial will be the results. Probably self-massage can be recommended more suitably as a treatment for constipation than for any other common condition, while as a substitute for or adjunct to regular exercise there is no doubt of its general value.

Sandow's Symmetrion Roller may be obtained from the Standard Health Appliance Co., Ltd., 7, Percy-street, W.1.

POPULAR BIOLOGY.

TWO volumes [1] of the "Science for You" series, recently published, contain together 35 longer and shorter essays on a variety of biological topics and are a sufficient answer to the complaint which is sometimes made that scientific people who find out things cannot explain their results to the lay public. Dr. Yonge's 14 chapters on marine fisheries are wonderfully interesting and just what are wanted, but he swallows too easily the idea that the disappearance of plague from England and Europe at the end of the seventeenth century was due to the replacement of *Mus rattus* by *M. decumanus*. Prof. Fox explains some of the recent work about respiratory pigments and Tyrian purple, writes of youth and age, the meaning of play, and the homing instinct, and gives an account of his own interesting study of the influence of the Suez Canal in allowing the animals of the Red Sea and Mediterranean to mix. This

[1] Queer Fish; Essays on Marine Science and other Aspects of Biology. By C. M. Yonge. Pp. 193. Blue Blood in Animals and other Essays in Biology. By H. Munro Fox. Pp. 205. London: George Routledge and Sons. 1928. 5s. each.

(*Continued at foot of next column.*)

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(*Continued from p. 216.*)

THE following is the text of the official bulletins which have been issued during the past week:—

FRIDAY, JAN. 25TH. 11.15 A.M.

The improvement in His Majesty's condition noted in the last bulletin continues. Bacteriological examination shows that the right chest is now free of the infecting organism. (Signed by Sir Hugh Rigby, Dr. L. Whitby, and Lord Dawson.)

SATURDAY, JAN. 26TH. 8.15 P.M.

His Majesty the King continues to make slow progress. (Signed by Lord Dawson.)

WEDNESDAY, JAN. 30TH.

The King continues to gain strength slowly, and His Majesty's progress is satisfactory. (Signed by Sir Hugh Rigby and Lord Dawson.)

(*Continued from previous column.*)

last article would be much better for a map and, indeed, a few good illustrations would improve many of the essays; they are perhaps impossible at the price. Both volumes have an article on the determination of sex; so has every other book on popular biology published in the last five years. The public must be growing very tired of it. One might say with the old Greek prose primer, "there ought to have been a law against love, so that all this trouble might not have been wasted."

ERYTHEMA NODOSUM.

IN the Long Fox Memorial Lecture delivered in the University of Bristol last year, and now published, Dr. J. Odery Symes takes as his subject the relationship between erythema nodosum and tuberculosis. He critically reviews the enormous continental literature, brings forward some weighty personal experience and some important case reports, and concludes that the association between the two diseases is beyond dispute. "Erythema nodosum," he says, "must always be regarded as a danger signal, as a timely warning that tuberculosis may exist or may develop. . . . While it is possible that tuberculosis prepares the soil for erythema nodosum, it seems more likely that erythema nodosum prepares the soil for tuberculosis; or if centres of latent disease exist in the bronchial glands or elsewhere, it lights them up to renewed and often fatal activity. The danger of this tuberculous infection is greatest during the first six months following the appearance of the rash."

NEW PREPARATIONS.

Diathermy Contact Soap.—Messrs. Rouse and Sons, Ltd., 50, Mortimer-street, London, W., have placed on the market a soap for use by those employing diathermy in their practice and who have experienced difficulty in the application of the electrodes. It has been found that the brine solution in which the felt-covered electrodes in ordinary use are saturated evaporates with the heat incidental to diathermy, when burning may occur, a trouble which it has been recognised can be obviated to a large extent by the use of any shaving soap. But even so an irritating action may be set up, while it is claimed that with this preparation a perfectly smooth contact can be made, the troublesome air bubbles not appearing. In appearance the soap resembles cold cream, and is smooth and easily handled.

Iodurum (Messrs. R. Demuth, 68, Salusbury-road, and Montrose-avenue, London, N.W.).—We have before now commented favourably upon various useful and elegant pharmaceutical preparations which have reached us from R. Demuth's laboratories, and the new preparation possesses both these qualities. The value of iodine as a universal antiseptic, especially as a first-aid adjunct, is now recognised in every household, so that anything leading to convenience of application should have a wide appeal. Iodurum is a solidified alcoholic solution of iodine, enabling the therapeutic properties of tincture of iodine to be employed in undiminished form in a clean and prompt manner. The nuisance of spilt iodine and the trouble of applying the tincture as a paint are matters of wide experience, so that a method of employment in which neither trouble can occur will be appreciated. Iodurum, an iodine stick, is supplied in a small glass tube enclosed in a metal case, and if the stick after use is replaced immediately in the tube, the tube corked, and the metal case carefully closed, the preparation will remain efficacious.

Hunterian Lecture

ON

LOCAL ANÆSTHESIA IN UPPER ABDOMINAL SURGERY.

Delivered on Feb. 1st, 1929, before the Royal College of Surgeons of England

By CHARLES A. PANNETT, M.D., B.Sc. Lond.,

FELLOW OF THE COLLEGE; PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; AND SURGEON TO ST. MARY'S HOSPITAL.

So magnificent was the boon conferred upon humanity by the discovery of general anæsthesia, so welcome the merciful oblivion to the patient and the untrammelling quietude of his body to the surgeon, so perfect and without danger have its methods become that it has been long accepted in England unchallenged as an almost ideal method for upper abdominal surgery. Yet, the operation completed, the aftermath is not invariably so satisfactory. There is an uncertainty about future events which is directly attributed to the inhalation of the anæsthetic. Damage to the parenchyma of the liver and kidneys, irritation of the lung endothelium, diminished oxygen-carrying capacity of the red blood corpuscles, the exhaustion from uncontrollable vomiting, the shock which comes on when the stimulation of the ether vapour is withdrawn, all tend to lessen the potential capacity for recovery of the patient, who must also run the risk of the inhalation of mucus and vomit during the unconscious period immediately succeeding the operation. It would be wrong to exaggerate these ill-effects of general anæsthesia, but it must be admitted by any impartial observer that the state of a man who has passed through an upper abdominal operation under local anæsthesia is very much better during the early post-operative period than that of him who has submitted to a general anæsthesia. This point need not be laboured. It is a simple demonstrable truth. Let us then turn to contemporarily available methods of local anæsthesia. They are: (1) local infiltration; (2) paravertebral anæsthesia; (3) splanchnic combined with anterior abdominal anæsthesia; and (4) spinal anæsthesia.

Successive local infiltration of structures before they are divided is not effective in abdominal operating so the choice lies between paravertebral, splanchnic, and spinal methods. They are all methods of conduction anæsthesia—that is, they attempt to abolish sensation over wide areas by interrupting nerve trunks. The difficulty is that the nerve-supply of the abdomen and its contents nowhere is limited in its path to a narrow area, such as prevails in the neck or upper limb. If a block of the nerves concerned is to be brought about outside the vertebral column, at least nine nerves on either side must be anæsthetised. This requires great skill on the part of the surgeon, occupies considerable time, and is a serious ordeal for the patient. I have devoted much time and labour in the attempt to perfect a reliable technique for paravertebral anæsthesia, but I have been driven to discard it as a practical solution of the problem. When it succeeds the anæsthesia is perfect, but if one nerve-root only eludes the needle the patient will retain pain sensation in some region of the operation area.

Splanchnic Anæsthesia.

Splanchnic anæsthesia, with which must be combined some method of anæsthetising the anterior abdominal wall, has been employed very widely abroad and quite extensively in this country. The splanchnic nerves pass through a comparatively narrow area where they traverse the diaphragm, and their block here abolishes sensation in the upper abdomen. An approach either from behind or, after opening the abdomen, from the front may be made. The posterior approach of Kappis has been used by some surgeons in this country, but always apparently in association with general anæsthesia, so that it is very difficult to say how successful it is. In one continental clinic where general anæsthesia is not added as routine it was stated that anæsthesia was successful in only 50 per cent. of cases. On the other hand, the anæsthetic fluid can be accurately placed where it is needed by the anterior route and the procedure is associated with less risk than the posterior method. Nevertheless, if no general anæsthesia is employed the technique of injection from the front is in itself painful and not always possible in the conscious patient. Though excellent anæsthesia by anterior abdominal block and anterior splanchnic block can be obtained, the method is not very well adapted to English patients, though circumstances may render it desirable, and a little general anæsthesia to allow of the splanchnic injection itself may make it possible.

I believe it better to avoid the administration of a general anæsthetic continuously throughout an operation under splanchnic anæsthesia, for I have received the impression that the post-operative course is no better than with pure general anæsthesia and lung complications seem to be quite as common. Splanchnic anæsthesia carried out as above is a valuable method which should be at the command of every surgeon. I have found it useful to modify Braun's original technique slightly. The vertebral column between the aorta and inferior vena cava is felt just above the pancreas with the pulp of the left index finger through the lesser omentum. The finger is kept close to the right side of the aorta, and the narrow tubular guide of the long fine needle is passed along its dorsum down to the vertebra and kept there by the middle finger. The needle is then passed down the guide as far as the bone, aspiration performed to prove the points of the needle not to be in a blood-vessel, and 30 c.cm. of 1 per cent. novocaine solution containing 20 drops of 1 in 1000 adrenalin per 100 c.cm. injected. Almost immediately the viscera fall back into the abdomen and render it quite easy to inject a further 10 c.cm. of the solution just to the left of the aorta behind the œsophagus. This injection is necessary to reach the left cœliac ganglion, for I have found, by trial with dyes in the dead body, that fluid injected only at the one point recommended by Braun sometimes fails to reach the left splanchnic nerves (Fig. 1).

Spinal Anæsthesia.

Leaving this method of anæsthesia, let us turn to the possibilities of spinal block, conduction anæsthesia carried as far back as is possible. Years ago spinal anæsthesia was used to a considerable extent, and Barker was able to show how high anæsthesia could be obtained by rendering the fluid used heavy enough to be able to control its position by altering that of the patient. But high anæsthesia by the technique then employed was found to be too dangerous and was given up so that, generally speaking, at the present time the spinal method is held to be suitable only for operations upon the lower part of the body. I hope to prove to you, however, that such high operations can be performed with safety and that there is a large field of usefulness for this anæsthetic method.

The problem in its simplest form is to bring an anæsthetic solution of sufficient strength in contact with the nerve-roots supplying the abdominal wall and the contained viscera—that is, roughly speaking, for upper abdominal work the roots of the sixth dorsal to the third lumbar nerves. The difficulty has always been to make a drug injected below the termination of the spinal cord diffuse up high enough to reach the fifth or sixth dorsal segment. There is one obvious and easy solution—namely, to inject the drug at that point of the spinal column where it is wanted. This practice has been indeed followed by a number of surgeons, but it is dangerous because of possible puncture of the cord and the production of a hæmatomyelia. The risk is one which should not be taken

where there is general anæsthesia as the safe alternative. For spinal anæsthesia puncture should always take place below the level of the lowest extremity of the spinal cord. It should not be higher than the interval between the second and third lumbar spines.

The Movement of Fluid in the Subarachnoid Space.

The question of the movement and final disposition of fluid injected is obviously intimately bound up with the natural flow of cerebro-spinal fluid about which we have not altogether precise knowledge. It seems to be well established that the fluid is secreted by the choroid plexuses of the lateral ventricles, flows through the foramina of Monro into the third ventricle, and thence by the aqueduct of Sylvius into the fourth ventricle. The foramina of Magendie and Luschka lead it into the subarachnoid space. The path of the fluid thence is not so clear. I quote from L. H. Weed [1]:—

"From cisternal dilatations of the subarachnoid space in the region of the cerebello-bulbar angle the cerebro-spinal fluid slowly seeps downwards in the spinal subarachnoid space, but passes more rapidly upward about the base of the brain and thence more slowly over the hemispheres. . . . In the spinal region there is also an almost equivalent passage of fluid upward."

H. Jackson [2] says that the fluid passes downwards along the posterior surface of the cord and upwards on the anterior aspect. A. Levinson [3] makes the same statement. Experimental demonstration of this fact, however, is far from conclusive, and I venture to affirm that no such circulation in the spinal canal does in reality take place. Wade himself injected into the lumbar region of the spinal canal potassium ferrocyanide and iron ammonium citrate in isotonic solution, and by acid fixation methods was able subsequently to find granules of Prussian blue in the whole spinal and basilar portions of the subarachnoid space which were "rapidly filled," whilst "the cerebral portion of the space was not completely injected until the experiment had been continued for several hours." But he injected the solution at a pressure of 130–180 mm. water, whilst the pressure of cerebro-spinal fluid in dogs is very constant and averages 112 mm. water, whilst that in cats averages 119 mm. water. It seems clear to me that he displaced the fluid in the spinal canal up into the cranial cavity until the venous pressure equalled the pressure of injection. His results could be explained in this way. In rabbits I performed the experiment (and repeated it) of injecting a few drops of a concentrated solution of methylene-blue under the arachnoid of the lumbar region of the cord after laminectomy, the animals being under the influence of urethane. After 45 minutes the animals were killed and the dye was found to have diffused only a few millimetres. There was no evidence at all of an active and vigorous circulation. It may be objected that in man after head injuries and sometimes after laminectomy large volumes of fluid escape in 24 hours. This large secretion may, however, very likely be an attempt to restore the cerebro-spinal pressure which is kept low by the leak in the dural sac, to its normal level, and therefore may have no bearing on the problem. If, as I believe, the absorption of normal fluid from the canal is only slight, necessitating little in the way of replacement, an anæsthetic injected into the dural sac would spread very slowly if it were dependent upon the physical process of diffusion alone. This is in agreement with the fact that 3 c.cm. of a 5 per cent. novocaine solution which is isotonic with cerebro-spinal fluid, injected between the third and fourth lumbar vertebræ, anæsthetises only that part of the body whose nerves pass downwards in the cauda equina.

An anæsthetic solution may be made to spread upwards above its point of introduction into the spinal canal (1) by altering the pressure conditions within the spinal canal before injecting; (2) by removing so much fluid and replacing it by an equal volume of anæsthetic solution; or (3) by making it either lighter or heavier than the cerebro-spinal fluid and altering the position of the patient.

FIG. 1.

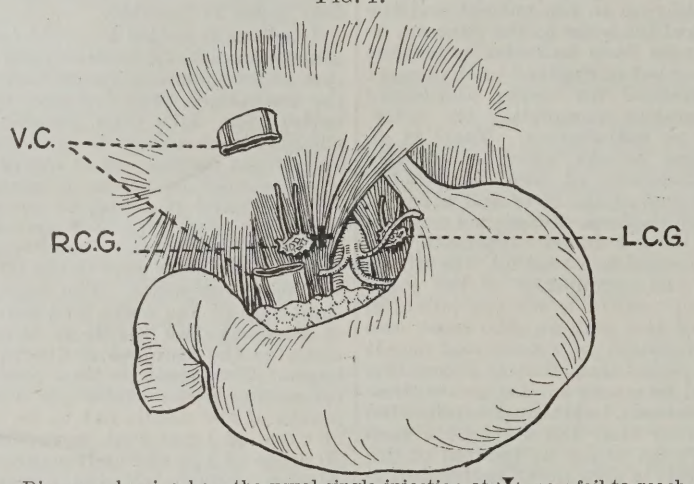

Diagram showing how the usual single injection at ✠ may fail to reach the left splanchnic nerves.

1. *The Reduction of Cerebro-spinal Pressure before Injection.*

This method was originally introduced by Le Filliâtre.[4] By removing definite volumes of cerebro-spinal fluid he was enabled to make the anæsthesia rise to any desired level and even to become general. The principle of the method is simple. The dural sac being enclosed in a rigid bony cavity, when fluid is withdrawn the space evacuated must be filled by increase of blood in the vessels in the intra- and extra-dural spaces. The veins in fact become engorged, and the intradural pressure is diminished to one-half if 30 c.cm. be withdrawn.[5] Weed showed that there is a great tendency to keep the pressure of the cerebro-spinal fluid constant hence, if after withdrawal a smaller quantity of anæsthetic solution be injected this will be more or less sucked along the subarachnoid space or at least it will be easily forced along it by pressure upon the piston of the syringe. Le Filliâtre uses a 2 per cent. cocaine hydrochloride solution as he says novocaine does not diffuse so well, takes away 25–30 c.cm. fluid, and injects 2·5–3·0 c.cm. of the solution. He injects forcibly and so must use a needle of large bore and practises "barbotage"—i.e., he injects and sucks out and injects again several times. The smaller amount will give anæsthesia up to the mammary line, the larger amount will cause generalised anæsthesia. He reports 9947 cases with two deaths, neither of which appeared to him to be due to the method. He says that if no more than 0·05 g. be injected no harm will result; 4 per cent. of his operations have been upon the head, 8 per cent. on the thorax, and 43 per cent. on the abdomen. No complications beyond two cases of severe headache and 4 per cent. of slight headache have occurred. Other surgeons have tried this method and met with accidents, but amongst his adherents are Masini, of Marseilles, and P. Delmas.[7]

Delmas, V. Riche,[8] and Bloch have used Le illiâtre's method with success, the anæsthetic agent eing novocaine. It would seem to be worthy of rther study, the chief objections to it being the use f a large bore needle which leaves a leaking hole in ıe dura and the necessity for extracting rather a rge quantity of cerebro-spinal fluid.

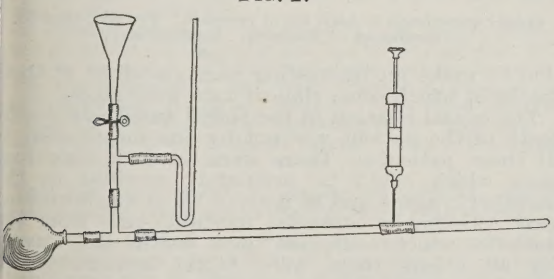
2. *The Replacement of Cerebro-spinal Fluid with Anæsthetic Solution.*

By dissecting out the cord in its membranes in an verage-sized man I found that when distended the ural sac up to the level of the sixth cervical vertebra ould hold 30 c.cm. of fluid. By an estimate which ust necessarily be rather inexact let us suppose the ac up to the level of the fifth dorsal segment to ontain 20 c.cm. of fluid, it might be possible to xtract this volume and replace it by a solution hich would then bathe the whole of cord which it is esired to anæsthetise. With this intent I aspirated 0 c.cm. of cerebro-spinal fluid from a patient with arcinoma of the œsophagus. The patient was then laced with the head low and 20 c.cm. of 0·5 per cent. ovocaine solution (0·10 g. novocaine) which is much ghter than cerebro-spinal fluid, injected. The result as that sensation was delayed and dulled up to the avicles but anæsthesia was not deep enough to llow the operation to take place. In another xperiment 15 c.cm. of fluid were withdrawn and 2 c.cm. of 1 per cent. novocaine injected. The esult was very similar. The strength of the novo- aine was apparently not sufficient to soak into the ervous tissue. I have not had the opportunity to y the effect of using a 1·5 per cent. solution; this ould mean using rather a large dose, but if the head ere kept low the solution would in all probability emain round the lower half of the cord, for the pecific gravity of it is only 1·0028 compared with ·006 of the cerebro-spinal fluid. This method is orthy of further study.

3. *Use of a Heavy or Light Anæsthetic Solution.*

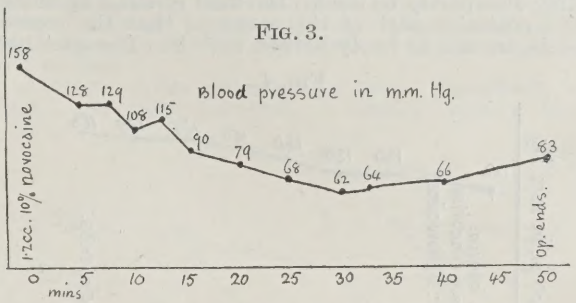
A solution much lighter than cerebro-spinal fluid ill rise to the highest point of the spinal canal and heavy fluid sink to the lowest level. The very areful work of A. E. Barker [9] in 1907 showed how a

FIG. 2.



eavy solution can be made to settle at the desired oint in the spinal canal. Barker's heavy solution ontaining stovaine and glucose is still used but not ften for high anæsthesia as Barker recommended. his is partly because stovaine is somewhat toxic nd many operators have therefore given up its use. ovocaine, being considerably less toxic, is a prefer- ble agent. A 10 per cent. solution has a specific ravity of 1·017. Tinged with a dye I have watched s behaviour when injected into the apparatus seen n the neighbouring sketch (Fig. 2). The glass tube epresents the spinal canal and holds approximately he same volume as that. The balloon at the end epresents the fluid in the cranial cavity; the pressure n the system can be varied by raising and lowering he funnel and is measured by the manometer; the oloured anæsthetic solution is injected by piercing he rubber connexion with the hypodermic needle of he syringe containing it. When the system was lled with a saline solution of the same specific gravity as cerebro-spinal fluid (1·006) and 1 c.cm. of coloured 10 per cent. novocaine injected with the tube sloped at an angle of 20 degrees with the horizontal, it was found that the anæsthetic solution settled down in a layer in the lower half of the tube and showed very little tendency to mix with saline solution. With this declivity it trickled down a distance equal to that between the third lumbar and fifth dorsal vertebræ (28 cm.) in 3¼–5 minutes. Alteration of the general pressure in the system by withdrawing fluid first did not seem to alter the rate of flow or tendency to diffusion in the least. These results cannot be applied without reserve to the

FIG. 3.



Typical fall of blood pressure in spinal anæsthesia. Male, aged 68. Carcinoma cæci. Ileo-transverse colostomy.

living body as the space between the cord and inner surface of the arachnoid is broken up by the anterior and posterior nerve-roots, the ligamenta denticulata, and a few other strands of arachnoid. These must obviously cause some obstruction to the flow of the anæsthetic fluid. It is essential to obtain anæsthesia that the novocaine solution should flow upwards behind the spinal cord in order to affect the posterior nerve-roots. When the amount of cerebro-spinal fluid is small and its pressure lower than normal, the head-down position may make so much of it flow out from the spinal canal into the cranial cavity that the cord may come to lie almost in contact with the membranes behind. Under such circumstances the solution deposited in the dural sac below the level of the cord may find it easier to flow upwards along its anterior surface, so that it may miss contact with the posterior roots or make irregular contact and so lead to imperfect anæsthesia. Some such explanation may account for failure where a good puncture has been made and the technique carefully followed out; in fact it has been suggested to me by the fact that it has seemed that anæsthesia has come on more quickly and extensively when the pressure of the cerebro-spinal fluid has been high than when it has been low.

Mention must be made here of a method of anæsthesia using a light solution developed by G. P. Pitkin[10] in America. Alcohol is added to lower the specific gravity and gliadin solution (prepared from starch) to render the liquid slightly viscid and inhibit the rate of diffusion. This author has also used a heavy solution of novocaine for obstetrical work.[11]

CHOICE OF ANÆSTHETIC AGENT.

Novocaine, being the least toxic of known local anæsthetics, would seem to be the best drug to use, but the objections have been raised that it is less certain in its action than cocaine or stovaine whilst muscular relaxation is not so complete. Both these facts are true. Novocaine seems to act more powerfully upon sensory than motor nerves. This can be demonstrated clearly by dissecting out the two sciatic nerves in a decerebrate frog, and painting that on the left side with 2 per cent. novocaine solution. On stimulating the middle of the painted area a contraction of the left limb occurred but no reflex contraction of the right limb. That the reflex path was not blocked was shown by stimulating the unpainted right sciatic when movements of both the hind limbs

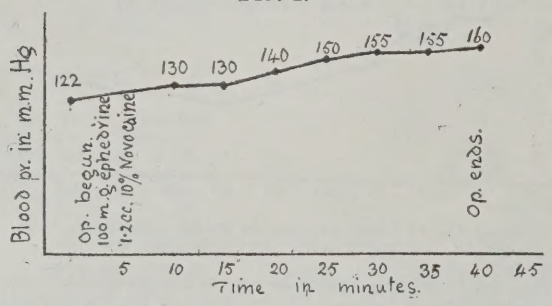
[8] Ibid., 1919, xxvii., 225. [9] Brit. Med. Jour., 1907, i., 665.

[10] Jour. of Med. Soc. of New Jersey, 1927.

[11] G. Pitkin and F. C. McCormack: Surg. Gyn. and Obstet., 1928, xlvii., 713.

occurred. Quite clearly, therefore, both excitability and conductivity of the motor fibres was retained in the painted nerve, whilst the sensory fibres were blocked. The muscular rigidity under novocaine spinal anæsthesia of which some surgeons complain is due to the fact that the anæsthesia did not extend high enough to block the splanchnic sensory supply. Under these circumstances pulling on the viscera will reflexly cause the abdominal musculature to contract. I have often demonstrated this, and I have observed several times whilst sewing up a laparotomy wound quite painlessly that the patient has been able to move his toes. This effect with a heavy solution may also partly be due to the fluid running up along the posterior part of the canal so that the motor roots are not so freely bathed with it. The question

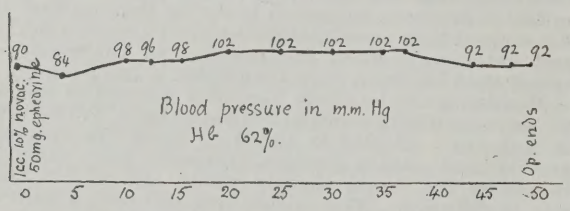
FIG. 4.



Effect of ephedrine on blood pressure in spinal anæsthesia. Carcinoma of stomach; exploration of abdomen.

arises whether adrenalin should be added to the novocaine or not. I rather feel with Barker that adrenalin, owing to the vascular spasm it produces, may do harm to the delicate nervous tissue, and there is some evidence to support this.[12] H. Hilarowiez and M. Szajna [13] assert that potassium chloride helps the penetration of novocaine and being a stimulant to nerve tissue lowers its toxicity. I have tried the addition of 1·1 per cent. KCl to the 10 per cent. novocaine, but have been unable to confirm their claims. Whether the viscosity of gliadin used by Pitkin lessens the rapidity of absorption of the novocaine into the veins and lymphatics, I do not know, but I believe it to be true that raising the blood pressure by the injection of ephedrine at the

FIG. 5.



Spinal anæsthesia in low blood pressure. Effect of ephedrine. Blood pressure maintained. Male, aged 42. Duodenal ulcer. Gastro-jejunostomy.

same time as the spinal injection leads to rapid absorption of the drug and diminishes the anæsthetic effect. Further investigation of this point is clearly necessary.

I do not give morphine or scopolamine before the operation. The latter is a dangerous drug of uncertain action, but I have of late given sodium veronal the night before and the morning of the operation. Agda Hofvendahl [14] and A. L. Tatum and K. H. Collins [15] have brought forward evidence showing that in the rabbit, dog, and monkey the convulsions of acute cocaine poisoning can be cut short and the animals recover from an otherwise fatal dose if sodium veronal be injected intravenously. Veronal also seems to act prophylactically. Although deaths from spinal anæsthesia do not usually seem to be due to a direct toxic action it seems to be a harmless and further

FIG. 6.

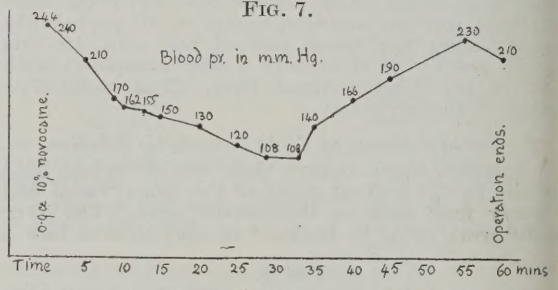
precaution to give preliminary sodium veronal medication.

DANGERS AND DISADVANTAGES OF SPINAL ANÆSTHESIA.

The crucial question of the risk of the anæsthetic must be faced and answered. If we restrict our investigations to death from novocaine spinal anæsthesia there are very few to be found in the literature, but it is likely that only a small percentage of such deaths are reported. As this applies equally to general anæsthesia, it is fair to compare the statistics of the two methods. The best collected series have been published by E. A. Rygh and D. H. Bessesen.[16] Amongst 250,895 administrations by 31 surgeons there were 75 deaths—i.e., 1 in 3345. They were

FIG. 7.



Spinal anæsthesia in high blood pressure. Female, aged 58. Carcinoma of stomach. Gastrectomy.

able to make an interesting analysis of 29 of these deaths of which some clinical data were given.

The causal relation of the spinal anæsthetic to the death of the patient was not by any means clear in all these patients. There were, in fact, only four cases which could be accurately ascribed to the anæsthetic agent and in none of these was novocaine used. Taking a corrected mortality-rate from the statistics which contained these deaths and leaving out all others there were 44,241 administrations with four deaths due to anæsthesia; mortality-rate 1 in 11,060. The mortality-rate of ether anæsthesia is calculated by Neuber as 1 in 5930.

There is more danger if the anæsthesia is made to extend up the cord than when it is only used for operations upon the pelvis and legs. If it reaches up to the fifth dorsal segment, as it must for upper abdominal operations, there is splanchnic dilatation and great fall of blood pressure which may be so low that the medullary centres are not kept oxygenated. The remedy for this is the head-down position; the injection of adrenalin which has only a short action, or better the administration of ephedrine. This last drug I believe to be of the greatest use. It causes peripheral vaso-constriction and keeps up the general blood pressure in spite of the block of the vaso-constriction fibres in the splanchnic nerves. A comparison of a typical blood pressure chart (Fig. 3), where no ephedrine was used with the two charts (Figs. 4 and 5), where this drug was administered soon after the spinal

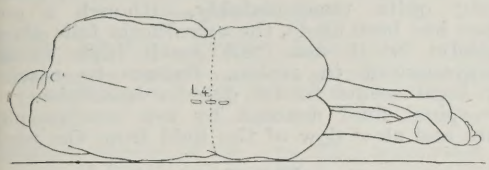
jection, shows how the dreaded drop in blood ressure can be completely avoided. Because of the ll in blood pressure hæmorrhage or shock are held

FIG. 8.



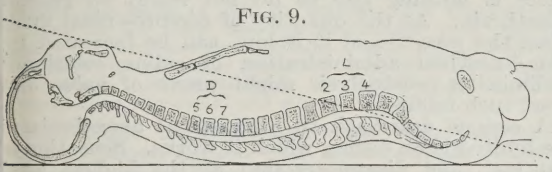
Position for injection.

be important contra-indications to spinal anæsesia. Desplas and P. Miller,[17] however, relate some traordinary cases of severe shock which were erated upon under spinal anæsthesia with success, nd the following case makes me wonder whether inal anæsthesia cannot be used with advantage in ses of hæmorrhage, especially now that ephedrine is ailable, a drug which I had not at my disposal hen I operated upon this patient.

A woman of 47 had been in hospital two years before for ematemesis.

March 24th, 1928: Readmitted for hæmatemesis; alleged have brought up 2 pints the evening before. April 2nd: spite of Lenhartz diet brought up 1 pint pure blood in orning and 1 pint blood and gastric contents in afternoon. h: Another pint of blood brought up; pulse 120. 5th: rgeon consulted; pulse 116, but fell to 110 before operaon; small wave; very severe anæmia, 40 per cent. emoglobin. Operation, using 1 c.cm. of 10 per cent. ovocaine intraspinally. There was no serious collapse

FIG. 9.



he dotted line represents the horizontal when the body is in the 20° head-down position. Note the relative directions of the spinal curves in this position.

nd the anæsthesia extended right up to the upper abdomeno chronic ulcer was found. The patient recovered in spite this needless operation.

On another occasion a woman of 51, very toxic, wasted om a growth of the sigmoid colon, had only 44 per cent. Hb. he usual technique with the head-down position for anæsesia was employed. She went through the resection peration without giving any anxiety. The blood pressure ll from 120 mm. Hg at the beginning of the operation to 4 mm. Hg its lowest point 27 minutes later. The pulse as 108 before operation, 112 at the end.

That the method can be employed when the blood ressure is low on occasion the following case shows:—

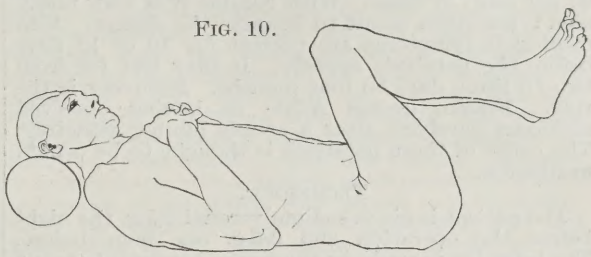
A man of 42 had recurrent symptoms of indigestion nd pain four years after a Billroth 1 operation. One month efore he was said to have had a hæmatemesis, and on his isit to the hospital he actually had one in the out-patient epartment. Hb. 62 per cent.; blood pressure 90 mm. Hg. njection of 1 c.cm. 10 per cent. novocaine hydrochloride ntraspinally with 50 mg. ephedrine subcutaneously. Good pper abdominal anæsthesia. Many adhesions found around te of old anastomosis fixing it to liver and gall-bladder. nterior gastro-jejunostomy performed. Blood pressure ever fell below 84 mm. Hg (see Fig. 5).

How great a fall of blood pressure can be withstood ithout danger to life I am not able to say. I have een very great diminution of blood pressure, and the atient, although looking pale and having a very eak wrist pulse, expressed himself as being comfortble. Thus a man who was having his prostate emoved suffered a drop in blood pressure from 160 o 68. Another patient, a woman of 30, with a blood ressure of 100 mm. Hg, was operated upon for gallstones under high spinal anæsthesia. Her blood ressure of 100 fell in 15 minutes to the extraordinary ow figure of 20 when ephedrine was given (Fig. 6). No alarm was felt for her safety. She was conscious, answered questions, and showed no signs of collapse.

Whether a high blood pressure is a contra-indication or not is also uncertain. A woman with a blood pressure of 240 mm. Hg had a gastrectomy for carcinoma performed. Her blood pressure fell to 120 mm. Hg. There was no anxiety about her condition felt (Fig. 7). The greatest depression lasts for only a short time when the pressure begins to rise again. The organism seems quite capable of functioning for a short time with a very low general blood pressure, the head-down position helping to maintain a sufficient circulation through the brain. It is possible, however, that too great a risk is run in the case of very old people with high spinal anæsthesia, for accommodation of the state of their vessels is not so easy.

Another contra-indication to spinal anæsthesia is said to be deep jaundice. I cannot support this

FIG. 10.



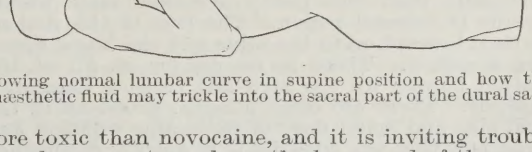
Showing obliteration of lumbar curve; the first position after injection.

contention; all the available evidence tends to show that spinal novocaine has less toxic effect upon the liver than general anæsthesia. I was once forced, because of a serious lung affection, to operate under spinal anæsthesia upon an intensely jaundiced woman who had had an obstruction of the common duct for some weeks. It was a complete success.

An important contra-indication to spinal anæsthesia would seem to be septicæmia, in which lumbar puncture itself is liable to be followed by the determination of the organism to the spinal canal.

Of paralyses of the sphincters, lower limbs, and cranial nerves after spinal anæsthesia it is difficult to find reliable information. C. Lepoutre[18] and P. Bazy[19] both relate single cases where some sphincteric trouble remained permanently after spinal anæsthesia. But no details of the operation are given except that they were hernias and no mention of the site of puncture, drug used, or dose. Stovaine is

FIG. 11.



Showing normal lumbar curve in supine position and how the anæsthetic fluid may trickle into the sacral part of the dural sac.

more toxic than novocaine, and it is inviting trouble to make a puncture above the lower end of the cord. There are, however, two cases of permanent paralysis after novocaine anæsthesia reported in the literature by M. Franke.[20]

(1) A varicose vein operation was done after the injection of 4 c.cm. of 5 per cent. novocaine-adrenalin solution. The patient died from pulmonary embolism on the sixth day, having had symptoms of myelitis. Post-mortem swelling of the cord and hæmorrhages up to the medulla were found. (2) After a similar operation the patient had symptoms of acute myelitis followed by paralysis of the legs, bladder, and rectum for two years. The tablets used were analysed and the adrenalin found to be decomposed.

[17] Presse médicale, 1918, xxvi., 234.

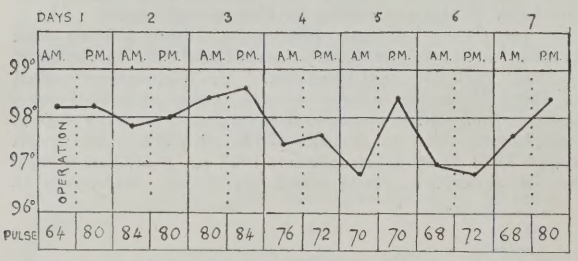
[19] Ibid., p. 243.
[20] Deut. Zeit. f. Chir., 1927, ccii., 262.

In 1906 Lieble, of Heidelberg, found such products of the decomposition of adrenalin to be irritating. Probably this is what caused the damage. Even pure adrenalin may be harmful as Barker pointed out (see above). It seems clear that adrenalin should not be employed in the spinal canal. Sometimes slight and evanescent meningeal symptoms appear after spinal anæsthesia. They may result from an irritation of the very sensitive membranes, for different observers have found a little increase of albumin, of the number of cells, of the sugar-reducing substance in the subsequently withdrawn cerebro-spinal fluid. Such symptoms never persist long. More serious are the ocular paralyses which sometimes come on after spinal anæsthesia. J. Rollet [21] has written a good account of them. He says the frequency is about 1 in 300 cases, but Bérard had only 2 in 3000 cases and Ducuing only 1 in 6000 cases. The abducent nerve is the one affected in 90 per cent. of cases. With cocaine it is very rarely seen; adrenalin seems to increase the danger. Mild meningeal symptoms are present for 10 or 12 days before the paralysis appears. It may last for from two to three days to four months. Recovery is the rule. Franke quotes Adam as having observed abducens paralysis after a simple lumbar puncture. The cause of these paralyses is thought to be a mild meningitis.

TECHNIQUE.

The patient is given sodium veronal 0·5 g. the night before the operation and 0·5 g. one hour before. The injection is made in the space between L. 2 and L. 3, or L. 3 and L. 4, in the middle line with a fine needle (1 mm. in diameter), the patient lying on his left side (Fig. 8). Cerebro-spinal fluid is not allowed to escape beyond a few drops and 1·0 to 1·2 c.cm. of 10 per cent. novocaine slowly injected. Immediately the patient is turned on his back and his legs flexed as in Fig. 10. If this were not done the solution might flow down into the sacral region, as can easily be seen from Fig. 11 drawn from Braun's plates and Fig. 9. At the same time the head end of the table is lowered

FIG. 12.



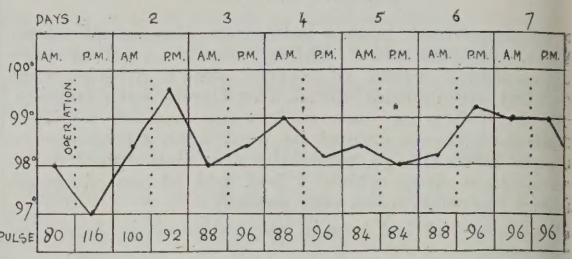
Female, aged 58. Carcinoma of stomach. Gastrectomy.

so as to make an angle of about 15 degrees with the horizontal, that the heavy solution may trickle towards the dorsal region. The legs of the patient are then lowered on to the table and the knees flexed over a pillow. There is no danger at all of the solution flowing up too high and causing dangerous paralysis. There are large margins of safety in the small size and small dose of novocaine solution and in the fact that the anæsthetic is quickly diminished in strength as it trickles upwards, partly because it becomes fixed by the nerve-roots, partly because of the rapid absorption which takes place from the spinal canal. The operation can usually be begun in about 8–10 minutes.

A great fall of blood pressure can be combated by the injection of ephedrine (0·05–0·1 g.). It is a little difficult to choose the right time to administer this. If given at the same time as the spinal injection a great and abnormal stimulus seems to be given to the circulation and the drug absorbed into the blood-vessels of the spinal canal before it has had good opportunity to soak into the nerves. It is probably better to wait until the blood pressure has fallen considerably, denoting that the anæsthetic has reached a fairly high level before giving the ephedrine, it being borne in mind always that absorption from the subcutaneous tissue in a collapsed patient is very poor.

Rarely quite unaccountably, although a good puncture has been made, the anæsthesia fails almost completely, or it does not reach high enough, or is evanescent in action. Failure to reach a proper level seems to be due to insufficiency of cerebro-spinal fluid denoted by low cerebro-spinal pressure and slow flow of the fluid from the needle

FIG. 13.



Female, aged 45. Hour-glass stomach. Billroth I. operation.

on puncture. Under such circumstances there is very little space between the cord and its membranes; indeed, in the dorsal position these structures may actually be in contact. There is a mechanical obstacle to the flow upwards of the anæsthetic solution behind the cord and between the maze of posterior roots. There is nothing else to do but resort to general anæsthesia. As the quantity of cerebro-spinal fluid, when the pressure of it is low, can be increased by intra-intestinal administration of saline solution,[22] preliminary proctoclysis might prove of value and avert such failures.

A serious drawback to high spinal anæsthesia is the limited time during which it works. Sensation is lost last, and disappears first at the highest level reached, so that it may be returning at the site of operation 45–50 minutes after the first incision was made. The time allowed is quite sufficient for a gastro-enterostomy or cholecystectomy, but is not always sufficient for a long gastrectomy. Under such circumstances I have been obliged to employ some general anæsthesia to complete the operation, but a plan has occurred to me which I have not yet put to the test. It is to finish the operation under anterior splanchnic block and local novocaine infiltration of the margins of the wound. At the stage at which such assistance is required the stomach and duodenum would be already cut across and the pancreas freely exposed to view. The splanchnic injection could be given with great nicety.

CONCLUSION.

High spinal anæsthesia, if a careful technique be followed, is accompanied by very little risk. It possesses many advantages over general anæsthesia, reducing to a minimum shock and post-anæsthetic disturbance. (Vide Figs. 12 and 13.)

It is not recommended that in the present stage of development it should be adopted as the routine method. A more perfect technique no doubt can and will be developed. As it is, it has reached a stage so satisfactory that certain operations become possible which otherwise would be fraught with great risk if performed under ether. It could certainly be used more frequently for upper abdominal work with advantage. Neither the technique recommended nor the views expressed in this paper have reached finality. The method seems to me to be in process of evolution. I have brought forward such facts as have come under my notice with the object of stimulating investigation and research in a very valuable surgical method.

THE BLOOD-PLATELETS IN SPLENIC ANÆMIA,

WITH SPECIAL REFERENCE TO TREATMENT BY SPLENECTOMY.*

By W. HOWEL EVANS, B.Sc., M.B. Liverp.,

LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL; ASSISTANT PATHOLOGIST, ROYAL INFIRMARY, LIVERPOOL.

Splenic anæmia, of the type often associated with the name of Banti, is a condition or group of conditions the pathogenesis of which is still quite obscure. In the original descriptions it is obvious that the term was used to include a number of specific conditions which have since been separated, such as syphilis, malaria, cirrhosis of the liver, aleukæmic leukæmia, and kala-azar (infantile splenic anæmia). The clear distinction of acholuric jaundice and the splenomegalies of the Gaucher, Niemann, and hypercholesterinæmic types still further encroach on the territory of "splenic anæmia." In the residue of cases after the exclusion of the above-mentioned groups the splenomegaly has been thought to be "primary" because of (*a*) the early appearance of the splenic tumour, (*b*) the appearance of fibrosis earlier in the spleen than in the liver, (*c*) the beneficial effects of splenectomy in many cases. Perhaps the best summarised description of the syndrome is that given by Tidy.[1]

"A chronic disease of unknown origin, characterised by enlargement of the spleen without enlargement of the lymphatic glands, by anæmia, recurrent hæmorrhages, and, in the later stages of certain cases, cirrhosis of the liver. Further, the group is akin to various other groups—e.g., to some of the liver and spleen diseases with varying degrees of icterus and hæmorrhages, and to some manifestations of the hæmorrhagic diathesis. Certain definite factors can produce indistinguishable syndromes—e.g., syphilis, thrombosis of the portal and splenic veins."

No definite infective agent has been constantly found, although Gibson [2] has described the isolation of a streptothrix from certain cases. It is possible that several ætiological factors still remain to be distinguished. The two chief theories of causation are:—

1. A primary inflammatory sclerosis of the spleen, ascribed, in the absence of any proved organismal agent, to a fibrogenic toxin (Moschowitz [3]). This supposes that the splenic sclerosis leads to increased blood destruction.

2. Primary vascular derangement. This was suggested by the frequent association—be it cause or effect—of thrombophlebitis of the splenic and portal veins. It is known that the congenital abnormality of persistence of the umbilical vein may cause a similar picture, suggesting that purely vascular disturbances can produce the syndrome. (Eppinger [4] has described two cases of this condition and mentions those of Cruveilhier, Baumgarten, Masura, Benque.) The present paper, however, limits itself to a consideration of thrombosis and hæmorrhage, and attempts to evaluate the importance of the blood-platelets in connexion with these two features, especially after splenectomy, which is admittedly the only effective treatment.

1. *Hæmorrhage.*

The best-recognised type of hæmorrhage in splenic anæmia is hæmatemesis, which occurs in a large number of cases, and may be massive and recurrent. It is ascribed to kinking of engorged vasa brevia or to dilated œsophageal varices. There is no doubt that in many cases this mechanical explanation is adequate. While hæmatemesis is frequent hæmorrhages from other sites are described, such as epistaxis, bleeding gums, hæmaturia, menorrhagia, hæmorrhages from the bowel, and even purpura. As long ago as 1914 Ziegler [5] suggested an associated hæmorrhagic diathesis, and since then the association of a diminished platelet count has been mentioned by Eppinger, Frank, and Rosenthal.[6] Eppinger [4] refers to a case of "fibro-adenie" with diminution of the platelets and purpura. Frank,[7] referring to the condition as "aleukia splenica," speaks of five cases of "splenopathie mit hypoleukie und thrombopenie." It is interesting to note that in 1921 so acute an observer as Moynihan [8] doubted that the mechanical explanation was sufficient entirely to explain the hæmatemesis, and suggested the possibility of a toxic origin. Thus hæmorrhage may be ascribed to (*a*) a local mechanical factor, and (*b*) a general hæmorrhagic tendency.

2. *Thrombosis.*

Thrombophlebitis of the splenic and portal veins, with sclerosis and sometimes calcification of the vessel wall, has been very frequently described since its demonstration in 1904 by Dock and Warthin.[9] It is uncertain whether the thrombosis or the splenomegaly is primary, or whether both processes may be produced contemporaneously by the same agency. Continental authors, notably Cauchois [10] and Eppinger, maintain that the thrombophlebitic changes are primary in the majority of the cases; Eppinger in particular would distinguish a "thrombophlebitic splenomegaly" differing both clinically and pathologically from Banti's splenomegaly. Clinically he describes splenomegaly, secondary anæmia, tendency to hæmorrhage, with a definite ætiological factor such as trauma, or childbirth, with ascites as a subsidiary aid to the diagnosis. He admits, however, that this description is not pathognomonic. Pathologically his account of the "thrombophlebitic" spleen is practically identical with that of the "Banti" spleen, the only differences being that in the former the thrombosis of the splenic and portal veins is more prominent, while the liver shows fatty but not cirrhotic changes. Kaznelson [11] insists that the thrombophlebitic splenomegaly can be diagnosed with certainty during life. He regards splenectomy as contra-indicated, partly because he regards the splenomegaly as secondary and partly because in four out of six cases described by Eppinger splenectomy did not in any way check the course of the disease. He also describes the case of a woman who, five years after splenectomy, died with thrombosis of both femoral veins, portal thrombosis, and ascites. He states that the platelets were numerous. The view usually held in this country is expressed in Tidy's summary that the syndrome produced by splenic and portal thrombosis is indistinguishable from the Banti syndrome. It is interesting to note that at any rate Kaznelson recognises (*a*) that there is a type of splenomegaly with a special tendency to thrombosis, and (*b*) that he regards splenectomy as inadvisable in these cases.

Recently attention has been called by the Mayo Clinic to portal and mesenteric thrombosis as a very fatal post-operative complication of splenic anæmia. W. J. Mayo [12] states that of the 10 per cent. of patients who died in hospital after splenectomy the majority died from progressive thrombophlebitis extending from the splenic pedicle into the portal system.

Wilkins,[13] investigating embolism and thrombosis in the portal system, comes to the following conclusion:—

"Splenic thrombosis usually results from splenectomy for splenic anæmia, by propagation of the normal process of thrombosis from the ligated end of the splenic vein. Thrombosis of the superior mesenteric vein usually results from retrograde extension of portal or splenic thrombosis, giving rise to mesenteric infarction. Splenectomy is the only type of operation which predisposes to mesenteric thrombosis, the factors being stasis from splenomegaly, cirrhosis, dilatation, and tortuosity of the splenic vein with degenerative changes in its walls, hæmorrhage from separating adhesions, trauma attending the removal of the enlarged spleen, ligation of the splenic vein, and finally infection, which is probably always present in the disorganised spleen and in the degenerated wall of the splenic vein in splenic anæmia."

The present communication owes its inception to a remarkable paper by Rosenthal [6] in which the importance of the blood-platelets in these two opposite conditions of thrombosis and hæmorrhage was first emphasised. He described a series of 16 cases of splenic

* A paper read before the Association of British Physicians.

anæmia splenectomised between the years 1909 and 1924. His description of the cases is as follows :—

"All these patients had splenomegaly, secondary anæmia, and leucopenia, and complained mainly of weakness, repeated gastric hæmorrhages, less often of nasal hæmorrhages, generalised bleeding (purpura), and pain in the left upper quadrant of the abdomen. Cases of syphilis, malaria, tuberculosis, leucopenic leukæmia, and cirrhosis of the liver were excluded from this group."

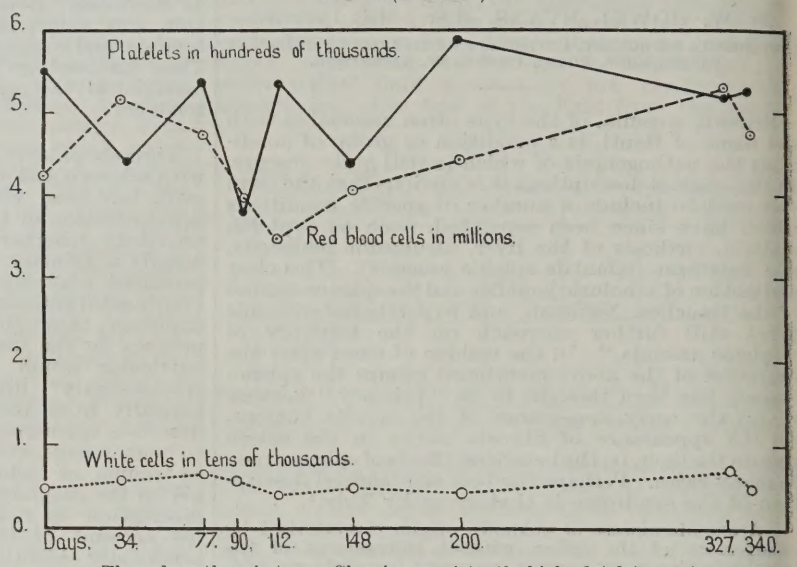
The operative results from the group of 16 cases showed 10 successes, 3 for as long as ten years, 1 for nine years. There were 6 failures with 3 deaths in the first year from widespread portal thrombosis. Three cases remained unimproved with repeated mesenteric and other thromboses. The last nine cases were studied in detail, especially on the platelet count before and after operation. On this basis he divided them into two groups :—

(*a*) *Thrombocytopenic Group* (five cases).—The platelets were very low before operation. After operation they rose for a short time and then fell to normal or slightly above. (In one case nine years after operation the count was 350,000.) In these patients the hæmorrhages were marked and were not always from the stomach (e.g., hæmorrhages from gums, epistaxis, hæmaturia, purpura). Rosenthal states that most of these patients had slightly prolonged bleeding time and in some cases poor retraction of the clot.

(*b*) *Thrombocythæmic Group* (four cases).—Platelets normal or somewhat subnormal before splenectomy, but afterwards rose rapidly to high levels (1,000,000+) persistently maintained for months and years. One case died from mesenteric thrombosis and three remained unimproved after suffering from thromboses in various sites—e.g., mesenteric, brachial, jugular, and femoral veins. In this group hæmorrhagic symptoms were less marked, and one of the cases gave no history of hæmorrhage before operation. In a few cases of apparent Banti's disease not splenectomised he observed "platelet crises" or marked temporary elevations which he thinks may produce thrombosis in the portal system before splenectomy. From these observations Rosenthal goes so far as to regard the two groups as ætiologically distinct. In the thrombocytopenic group he considers the splenomegaly to be primary, on account of the good results of splenectomy which he ascribes partly to the removal of a thrombocytolytic factor and partly to the mechanical relief of engorged abdominal veins and viscera. The suggestion here is that either the primarily diseased spleen is overactive in destroying platelets produced in normal numbers or that it inhibits production. In the thrombocythæmic group he thinks that the primary factor is an increased production of platelets, comparable to the increase of leucocytes in leukæmia, and that the splenic enlargement is secondary and represents an attempt to keep down the numbers of the circulating platelets—assuming that the spleen is the main platelet-destroying agency. After splenectomy fatal thrombosis may occur before the rest of the reticulo-endothelial system becomes adequate to deal with the increased number of platelets. Rosenthal does not correlate his "thrombocythæmic group" with the "thrombophlebitic" type, and states that they did not correspond with Eppinger's thrombophlebitic type.

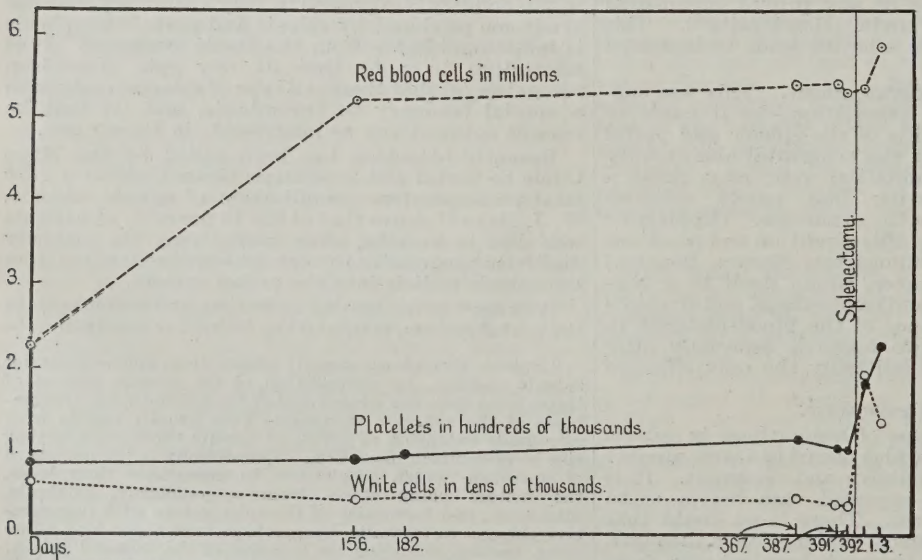
While his interpretation may be open to discussion, his paper is especially important because it is the first serious study of the platelets during life in splenic anæmia, and because it attempts to correlate the increase of the platelets with the tendency to thrombosis.

FIG. 2 (Case 15).



Thrombocythæmic type. Showing persistently high platelet count.

FIG. 1 (Case 5).



Thrombocythæmic type. Showing persistently low platelet count.

Since reading Rosenthal's paper I have had the opportunity of observing 19 cases of splenomegaly with anæmia which may fairly be described as "splenic anæmia" from the following criteria.

1. Anæmia with little evidence of regeneration (no increase of reticulocytes and nucleated forms) except in immediate post-hæmorrhagic regeneration.
2. Leucopenia as a rule—never leucocytosis.
3. Absence of clear evidence of hæmolysis—i.e., van den Bergh reaction normal; fragility normal; the only possible evidence of hæmolysis being increased output of urobilin.
4. Wassermann negative.
5. No other obvious cause.

In addition to these 19 cases three apparently similar cases were found to have a strongly positive Wassermann reaction—a high proportion, emphasising the importance of excluding syphilis. In nine of the cases only a single routine observation was made, but in the others a number of records were taken. The platelets were counted by an indirect method, modified from that described by Bedson,[14] which gives an average count of about 300,000 for a large number of normal persons. It will be seen from the table that in the platelet count the cases fall into three groups.

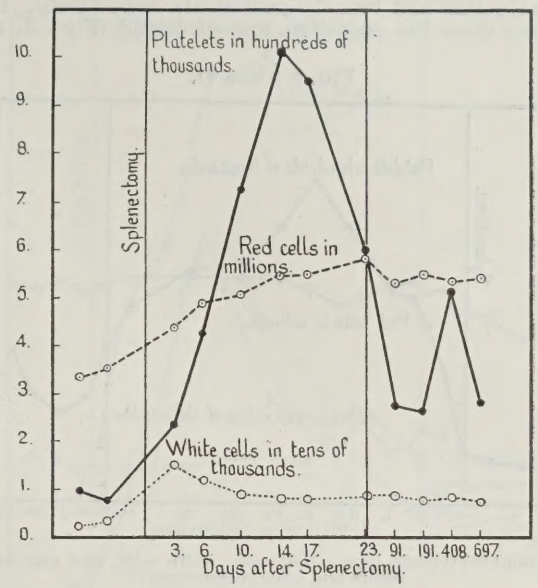
Group 1 (*Cases 1–9*), corresponding to Rosenthal's thrombocytopenic type. The platelets are markedly reduced, most of the counts falling round about 100,000, the lowest count being 53,000 in Case 9. Leucopenia was also definite. All these cases gave evidence of hæmorrhagic tendency; four had repeated hæmatemesis, epistaxis occurred in five cases, bleeding gums in three, purpura in three, menorrhagia in two. As a general rule there was moderate prolongation of the bleeding time and the clots retracted poorly.

That the thrombocytopenia may be persistent is shown in Case 5 (Fig. 1). This patient was observed for a year before splenectomy and, in spite of the repair of the anæmia which followed a large hæmatemesis shortly before he was first seen, the platelets and leucocytes) remained persistently low during the whole period.

Group 2 (*Cases 10–16*).—In this group, corresponding to Rosenthal's thrombocythæmic group, the platelets were normal or, as in Case 15, increased. The leucocyte counts also were not quite so low. In six of the seven cases no history of hæmorrhage could be obtained, and the bleeding time and clot retraction were normal.

Case 15 (Fig. 2) is especially interesting. Observed for about a year, the platelets were always distinctly above normal. The bleeding time varied from normal (one and a half minutes) to five minutes. Clot retraction was always good, and clotting time rather reduced. During this period the patient had several attacks of abdominal pain followed by melæna, which were at first thought to be due to minor mesenteric thromboses. Recently, however, he has had purpuric hæmorrhages for which it seems impossible to account on a basis of thrombosis.

FIG. 3 (Case 4).



Thrombocytopenic type. Red cells, white cells, and platelets, before and after splenectomy.

Group 3 (*Cases 17–19*).—These cases show intermediate counts, but further study of this group is desirable, as in Cases 18 and 19 only a single observation was made.

Further observations, which cannot be dealt with fully here, were that in the low platelet cases a slight delay in clotting time and marked failure of clot retraction were invariably present, whereas in the thrombocythæmic group the clotting time was normal or somewhat shortened and the clot retraction good. After splenectomy the clotting time shortens slightly during the period of platelet elevation in all the cases, and returns to normal as the platelets return to normal. The retractibility of the clot is also much increased. In the only thrombocythæmic case splenectomised the shortening of clotting time was persistent and

TABLE SHOWING BLOOD FINDINGS AND CHIEF CLINICAL SYMPTOMS IN NINETEEN CASES OF "SPLENIC ANÆMIA."

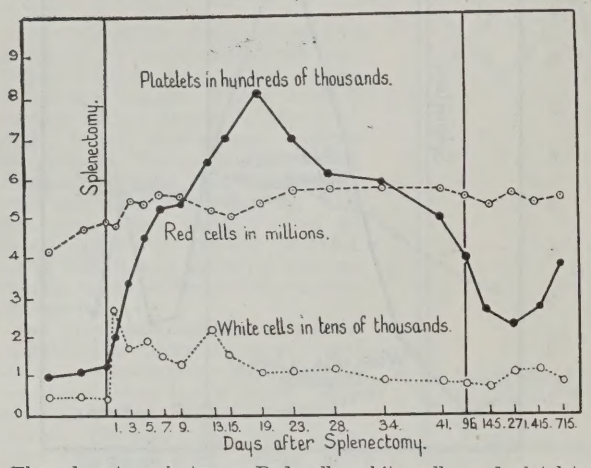
13	5	M.	40	3,850 (0·8)	7188	292	1½	3 mths.; weakness; anæmia; not seen again.
14	53	F.	45	4,850 (0·3)	3188	287	"Normal"	3 yrs.; pain; weakness; no hæmorrhages.
15	25	M.	48	4,260 (0·7)	4843	550	1½ and 5	3 yrs.; pains; dyspepsia; hæmorrhage from bowel; purpura.
16	7	M.	30	2,880 (2·4)	6568	354	2	6 mths.; weakness; anæmia; no hæmorrhages.
17	34	M.	88	4,700 (0·3)	3125	191 and 148	1½	1 yr.; weakness; pain; no hæmorrhages.
18	30	F.	38	4,200 (0·8)	4062	151	1½	5 yrs.; recent large hæmatemesis; pain.
19	29	F.	45	3,420 (0·5)	6875	163	2½	6 mths.; pain; weakness; no hæmorrhages.

progressive until death. Full details are given in a paper in the *Journal of Pathology and Bacteriology*, 1928, xxxi., 815.

Operative Results.

Thrombocytopenic Group.—Five cases were splenectomised and two died on the fifth day from intestinal obstruction and broncho-pneumonia respectively. In three cases the operation was successful (Figs. 3, 4,

FIG. 4 (Case 7).



Platelets in hundreds of thousands.

and 5†); two of these have been followed for two years. No. 6 absconded from the hospital a few weeks after the operation and was not traced. The platelet curves of these three patients are very similar. The platelets rise after splenectomy to a maximum of about a million in a little over a fortnight, and a further fortnight sees a considerable return towards normal. A normal count was reached in Cases 4 and 7 in about 90 days, and since then the platelets have fluctuated but little. Two years later both patients are well, the anæmia has disappeared, no further hæmorrhages have occurred, and both are back at work, No. 7 as a coal-miner and No. 4 as a housewife. Although the observations in Case 6 only covered 32 days, the shape of the platelet curve is quite similar to the others. It cannot be said that restoration to health for a period of two years is conclusive proof of complete cure, seeing that in many cases the natural course of the disease without splenectomy may be much longer than this. In both cases, however, the condition before operation was desperate—they certainly would have been dead by now unless they had been relieved.

Case Reports of Splenectomised Cases.

Thrombocytopenic Group.—CASE 4, female, aged 34. Five years' history, beginning shortly after delivery. Onset with anæmia, weakness, and left-sided pain. In the last two years bleeding gums and generalised purpura. Wassermann negative; van den Bergh less than 1 unit; urobilin in urine increased. Operation Feb. 21st, 1926. Weight of excised spleen 1380 g.

CASE 6.—Male aged 19. Two years' history, weakness and left-sided pain. Occasional nose-bleeding and frequent oozing from gums. Slight trauma produced severe ecchymoses. Wassermann negative; van den Bergh less than 1 unit; urobilin in urine increased. Operation Feb. 15th, 1927. Weight of excised spleen 1470 g.

CASE 7.—Male aged 29. Attacks of left-sided pain for seven years. Recurrent large hæmatemeses at intervals in the last four years. X ray of stomach negative. Wassermann negative; van den Bergh less than 1 unit; urobilin in urine usually normal. Operation Nov. 17th, 1925. Weight of excised spleen 840 g.

CASE 5.—Male aged 18. Large hæmatemesis when 8 years old. Afterwards always delicate, but no further hæmorrhages until ten years later, when there was rapid development of anæmia culminating in a massive hæmatemesis. Severe epistaxis shortly before splenectomy. Wassermann negative; van den Bergh less than 1 unit; urobilin in urine usually normal. Operation Oct. 28th, 1927. Spleen buried in dense adhesions; operation completed with difficulty. Weight 640 g. Intestinal obstruction due to kinking of splenic flexure. Death on the fifth day. Necropsy refused.

CASE 9.—Male aged 56. About ten years' history of anæmia and splenomegaly. Much X ray treatment to spleen in earlier stages. In last four years repeated large hæmatemeses; several just before operation. Slight icteroid tint. Wassermann negative; van den Bergh indirect test gave 1·5 to 2 units; urobilin in urine markedly increased. Operation Dec. 30th, 1927. Weight of excised spleen 1520 g. Death from broncho-pneumonia on fifth day. Necropsy refused.

Thrombocythæmic Group.—Only one splenectomy was performed. As this patient died from mesenteric thrombosis splenectomy has been considered unjustifiable in other cases of this type.

CASE 10.—Male aged 16. Anæmia for some years. For two years pain, weakness, and increasing anæmia with nausea and occasional vomiting. No hæmorrhage. Wassermann negative; van den Bergh less than 1 unit; urobilin in urine markedly increased. Operation Sept. 29th, 1926. Weight of excised spleen 380 g. Persistent elevation of platelets after splenectomy with death on the thirty-first day. Several examinations of the stools in the few days immediately before death showed the presence of occult blood. Necropsy showed a recent thrombosis spreading from the splenic pedicle into the uppermost branches of the superior mesenteric vein, with gangrene of a proximal loop of the small bowel. The portal vein was patent. The splenic and superior mesenteric veins showed histologically a moderate degree of thickening, but no old thrombosis and no calcification. The liver showed a moderate degree of fatty change, but no cirrhosis.

The Morbid Histology of the Excised Spleen.

This paper does not concern itself with the histopathology of the disease and detailed descriptions are therefore omitted. It is, however, important to

FIG. 5 (Case 6).

mention that the six spleens examined gave no evidence of other specific disease. They all showed very close resemblances, and no histological difference could be determined between the five spleens from the low platelet cases and that of the single thrombocythæmic case. Thickening of the capsule and trabeculæ was constant. Overgrowth of the reticulum cells with irregularly spreading fibrosis was present in

† Figs. 3, 4, 5, and 6 are reproduced by the courtesy of the Editor of the Journal of Pathology and Bacteriology.

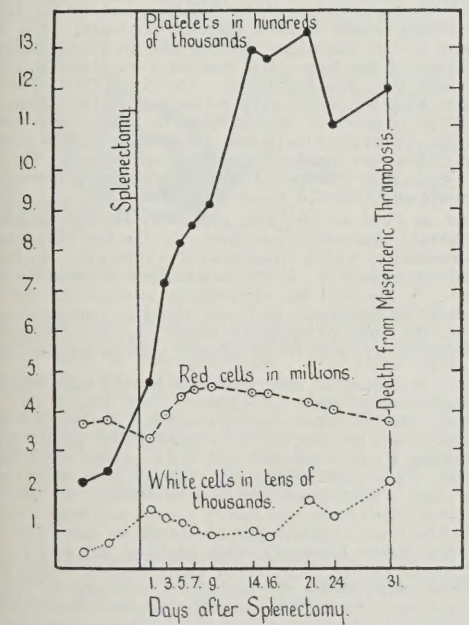
arying degree, but always marked. The fibrosis of he pulp encroached on the lymphoid follicles in an rregular way; in some parts of the organs the follicles vere fairly numerous, in others almost completely lestroyed. In those follicles which remained the ymphoid elements appeared fairly normal, but hyaline hickening and tortuosity of the Malpighian artery was nvariably present. The splenic veins in the trabeculæ n most of the cases showed some degree of hyaline hickening, but thrombophlebitis within the organ tself was never observed. Examination of the stumps f the splenic veins at the hilus in all the cases showed ome degree of thickening and sclerosis, but never alcification. In Case 4 one of the large branches of he splenic vein was partially occluded by organised lot. Sections prepared by Levaditi's method were egative for *Spirochæta pallida* in all cases. Cultures vere made in four cases and were entirely negative. n no case was there evidence of siderosis.

This description agrees with the commonly described norbid changes in the Banti type, and more closely vith Eppinger's "Banti-milz" than with his thrombophlebitischer Milz."

Discussion.

It is evident from this confirmation of Rosenthal's vork, coupled with the observations of Kaznelson and Mayo, that the platelets are of considerable importance n splenic anæmia. First, it seems clear that in the ow platelet type of case, with subjective and objective vidence of hæmorrhagic tendency, splenectomy may e confidently recommended. Such patients are not mmune from the usual surgical risks, as shown by the wo post-operative deaths in the present series. If, owever, they survive the immediate operative azards, there would appear to be a good prospect of estoration to health. In the majority of our cases the peration was made appreciably easier by preliminary lood transfusion, which is desirable in cases with

FIG. 6 (Case 10).



Thrombocythæmic type. Red cells, white cells, and platelets, before and after splenectomy.

hæmorrhagic tendency. In the other type of case, on the evidence available, splenectomy does not appear to be justified, as it exposes the patients both to the immediate risks and to the apparently inevitable danger of mesenteric or other thrombosis. On the other hand, it seems hardly justifiable to refuse splenectomy to patients who are doing badly, and appear likely to die unless relief is given. In these cases, however, the operation should only be undertaken with a very distinct realisation of its risks.

In the present state of knowledge it seems unsafe to go further and to make a definite ætiological distinc-

FIG. 7.

tion between the two types of case. In view of the current belief that the platelets are produced by the bone-marrow and destroyed by the reticulo-endothelial tissue in the spleen and elsewhere, Rosenthal's theory is tempting, but requires more support before it can be accepted. Further observations may yield important evidence both in regard to the origin of "splenic anæmia" and to the mechanism of platelet regulation.

Conclusions.

1. The hæmorrhagic tendency in splenic anæmia may be due to two factors: (*a*) A mechanical factor probably related to venous stasis associated with splenic and portal thrombophlebitis (hæmatemesis). This factor is not necessarily associated with thrombocytopenia. (*b*) An associated general hæmorrhagic tendency, which may be correlated with a deficiency of platelets. Such patients appear to be good operation risks and the prospects of permanent relief by splenectomy seem good.

2. Thrombosis of the splenic veins and portal vein is of frequent occurrence. It is possible in some cases that the venous thrombosis is the primary event (Eppinger's thrombophlebitic type), but differential diagnosis during life seems impossible.

3. Thrombosis, both in the portal system and in peripheral sites, may occur as a post-operative complication and may be correlated with a gross and persistent increase in the platelets after splenectomy. In some cases not operated on "platelet crises" may occur (Rosenthal) and possibly may be correlated with splenic and portal thrombosis.

4. It appears that, in the majority of patients exhibiting this thrombotic tendency, the platelets before splenectomy are usually normal or elevated. In these patients there appears to be considerable risk, after splenectomy, of thrombosis, which may be fatal. One cannot therefore recommend splenectomy with the same confidence as in those cases which present

thrombocytopenia associated with evidence of subjective and objective hæmorrhagic tendency.

It is a pleasure to acknowledge the interest taken in these investigations by my medical and surgical colleagues at the Royal Infirmary, Liverpool. I would particularly thank Prof. John Hay, Dr. J. C. Matthews, Dr. Henry Cohen, Mr. H. F. Woolfenden, and Mr. Frank Jeans, who have at all times given me the freest access to their cases, and permission for publication. I should also like to thank Mr. O. H. Williams, surgeon to, and Dr. C. H. Walsh, resident medical officer of, Mill-road Hospital, Liverpool, for similar permission in regard to two of the operated cases.

HYPERTROPHY OF THE DISTAL PORTION OF THE ILEUM.

WITH A REPORT ON TWENTY-EIGHT CASES.

BY ROBERT MACKINLAY, M.B. TORONTO.

Sir W. Arbuthnot Lane, in his paper on the treatment of "Non-malignant Affections of the Colon,"[1] states: "This ileal kink is caused by an evolutionary band produced by abnormal loading of the bowel which is aggravated by the 'first and last' kink." For reasons suggested by the series of cases here described I believe that this ileal kink is caused by the cicatrisation of the lower leaf of the mesentery of the ileum as a result of recurrent attacks of appendicitis.

Six Representative Cases.

CASE 1, a man of 35, was in really good health until 1912, when, at the age of 20, he began to have what he called "bilious spells" of headache, vomiting, and abdominal pain. These spells gradually got worse and became more frequent. In 1915 the case was diagnosed as recurrent appendicitis, and appendectomy was advised. A diseased appendix was removed. His condition was not improved, and as time went on it gradually grew worse; the old symptoms were exaggerated and new ones gradually developed, until finally he never felt well. He was treated by me from 1921 to 1927 for gastro-intestinal disorders and cholecystitis. During that period I used alkaline bismuth mixtures, dimol, tonics, and lastly, large doses of hexamine with sodium bicarbonate, over a long period. The last-mentioned helped slightly, but the former did not help in the least. In 1927 he took an ocean trip, crossing the Atlantic twice, but this did not help. In the same year I advised a laparotomy and on May 27th I operated.

The symptoms just before the operation were: 1. Pain between the shoulder-blades—the most constant symptom. 2. Pain beneath the right costal margin, radiating round to below the right shoulder-blade. 3. Gas and a sour, hot, burning feeling in the stomach (so-called indigestion) after eating. What he ate did not seem to make any difference. 4. Frequent vomiting of meals, with much mucus, immediately after eating. 5. Severe pains in epigastrium at times. 6. Obstinate constipation. 7. Absence of any ambition or joy in living. 8. Nervousness, irritability, and inability to sleep well. 9. Much right frontal headache. 10. Constant weak miserable feeling. 11. Failure to feel refreshed after a night's sleep.

[1] THE LANCET, 1922, ii., 114.

The signs just before the operation were: loss of weight (140–118 lb.); pinched nervous expression; constant brownish-yellow tinge to skin; and tenderness over gall-bladder area.

The operation findings were: normal gall-bladder and cystic duct; normal liver and bile-ducts; normal stomach and duodenum; appendix had been cleanly removed. About six inches from the ileo-cæcal valve there was a marked contraction and thickening of the lower leaf of the mesentery supplying the ileum. This diseased area was about two inches long and caused a marked kinking and torsion of the ileum at that point. The walls of the ileum distal to the diseased lower leaf of the mesentery (i.e., from the kink to the cæcum) had the appearance of containing more blood than the normal proximal portion, were much thickened, and had a rubbery consistency. This contracted thickened lower peritoneal leaf was cut completely through and stretched so that the blood-vessels and subperitoneal structures of the mesentery were exposed. When this was done the kinking and torsion of the ileum were corrected and the circulation in the diseased portion of the ileum was improved.

On Sept. 25th, 1928, the patient reported as follows: 1. Gained 15 lb.; weight 133 lb. 2. Has a little gas after eating only when worried or when he bolts his food. These are the only occasions when food is brought up. 3. Has no mucus (or "phlegm" as he calls it). 4. Has no gnawing or sour, hot feeling in stomach. 5. Has no epigastric pain, but occasionally feels a little pain between his shoulder-blades. 6. Bowels evacuate regularly without medicine and are not in the least constipated. 7. Is full of "pep" and now can go out and enjoy life after a day's work. 8. After a hard day's work he sleeps restfully and awakens refreshed. 9. Not nearly so nervous and irritable. 10. He states that, though the immediate improvement was marked, he continues to improve.

CASE 2, a boy of 11, was well until 4 years of age, but since then has never had good health. He had frequent bilious attacks (vomiting, severe frontal headache, and felt very weak), which lasted from a few hours to two days. These bilious spells usually started at night, but strenuous games or indiscretion in eating would cause them. He never felt hungry and had much frontal headache. He was not constipated. He had very marked choreiform habits such as blinking, sniffing, and irregular movements of head and hands. He had a dry skin and much trouble with eczema between his fingers. He had frequent colds. He was lethargic and found it very difficult to learn. His hands felt numb in the mornings and he had frequent cramps in the muscles of his legs. His tonsils were slightly infected and he had two infected teeth. On Nov. 28th, 1927, his appendix was removed with adhesions. The ileum was kinked by a marked contraction in the lower leaf of mesentery supplying the ileum, about four inches from the cæcum. This was freed as described in Case 1. The walls of the ileum were thickened and of a rubbery consistency. The tonsils and infected teeth were removed.

Report on Case on Oct. 1st, 1928.—1. He has not had a bilious attack since the operation. 2. He has only had one slight headache, which disappeared overnight. 3. He has an excellent appetite. 4. He has had no eczema since and no colds. 5. He still has choreiform movements, but they are greatly diminished, and are steadily improving with time. 6. He finds it easier to learn. 7. Numbness occurs only occasionally, and he has fewer cramps in the legs.

CASE 3, a man of 41, complained of having had indigestion and constipation since childhood. At times any food caused discomfort after eating (burning feeling below the umbilicus) and he frequently vomited his meals shortly after taking them. He suffered with severe right frontal headache, especially during the winter, and most of the time he had a trembling, nervous sensation. Of late years he has always felt tired and heavy; work has been a drudge and his legs have at times felt too weak to carry him. His skin had a sallow brownish tinge and felt dry and burning. A few weeks before June 19th, 1928, he had slight cramp in the abdomen, below the umbilicus, centring to the right of the mid-line. In 1916 he consulted a prominent physician in Toronto and was given a very thorough examination. The diagnosis was "neurosis of the stomach" and treatment was instituted. No improvement was noticed, although the instructions were closely followed.

On June 19th, 1928, I operated and found an appendix which showed evidence of having had inflammatory attacks and was firmly adherent to the lower side of the mesentery three to five inches from the ileo-cæcal juncture. It caused a marked kinking of the ileum at this point. The ileum distal to the kinking and extending to the cæcum was congested and thickened, and had the rubbery feeling noticed in other cases. The appendix was removed and the kink released by cutting across the thickened fibrous leaf of the mesentery involved. A few bands of adhesions of

the upper cæcum and ascending colon were also freed. The patient felt and looked very sick for ten days, and from then on he steadily improved.

Report on Case on Oct. 7th, 1928.—1. Since his operation he has been able to eat any ordinary food without the least discomfort. 2. He has a good appetite and has gained 10 lb. in weight. 3. His skin has lost the dry, burnt feeling and is moist and soft. He has lost the sallow tint and the heavy depressed appearance. 4. The tired feeling in his legs is gradually disappearing. 5. He does not feel or look nervous. 6. He has had no headache. 7. He is not constipated. To use his own expression, "I have never felt like this before."

CASE 4, a man aged 51, had symptoms similar to those described in Cases 1, 2, and 3, except that for the two days before his operation he was unable to get his bowels to evacuate and had very severe cramps. At operation I found a subacute appendix surrounded by adhesions which continued along the mesentery of the ileum and bridged across to the upper part of the sigmoid colon, where they left a ring of about one and a half inches in diameter. Passing through this ring was a much distended loop of descending and sigmoid colon about two feet in length, and also a loop of distended, thickened ileum two or three feet in length. I believe these loops had been in this position for some time, but owing to the increased congestion caused by the subacute attack of appendicitis a complete obstruction resulted. The thickened contracted lower leaf of the mesentery was freed by cutting for a distance of about eight inches—that is from the appendix to the sigmoid colon—and in this way the obstruction of the colon and ileum were released.

The convalescence of this patient was slow. At the end of ten days the abdominal suture began to give way and pus exuded from the wound. Finally, the whole wound gaped down to the peritoneum. Gradually the patient's condition improved and the wound was resutured and united well. The patient was discharged from hospital on Oct. 22nd, 1927. I saw him last in July, 1928, pitching hay in the mow. He claimed that he felt better than he had for years. He had a good appetite and was able to eat ordinary food without discomfort. He was not constipated. He had gained considerable weight and now had a cheerful outlook on life.

FIG. 1.

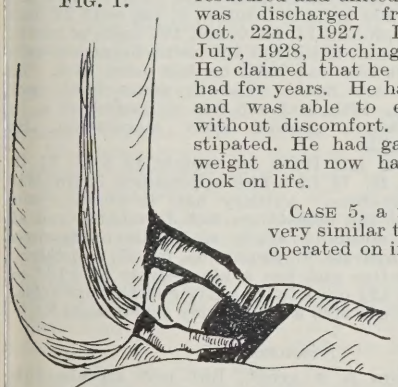

Diagram showing area affected.

CASE 5, a man aged 55, was very similar to Case 4. He was operated on in November, 1927, and presented the most extensive formation of scar tissue I have seen, resulting from what I believe were recurrent attacks of appendicitis.

CASE 6, a girl of 16, had signs and symptoms of acute appendicitis. She gave a history of recurrent similar attacks, but had felt well in the intervals. On June 28th, 1928, an operation was performed and an acutely inflamed appendix with a bulbous end was removed. A dense scar about one-half by one-quarter of an inch was situated on the lower leaf of the mesentery of the ileum about two inches from the cæcum. The ileum was normal. I mention this case because it illustrates the beginning of the thickened contracted mesenteric leaf referred to above.

Grouping of Cases.

I have selected these six cases as representative of the series of 28 cases I have observed, and they conveniently fall into three groups.

Group 1.—Case 6 illustrates a number in which the cicatrisation of the mesentery has just begun and has not interfered with the circulation of the mesentery and the ileum. In these cases no symptoms other than those of appendicitis were produced.

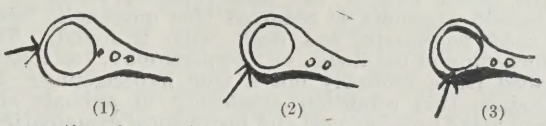
Group 2.—Cases 1, 2, and 3 are representative of those where the formation of scar tissue in the mesentery has caused a mechanical interference to the circulation of the mesentery and the distal portion of the ileum, but has caused no mechanical interference with the passage of fæces. In these cases we find superimposed upon the symptoms and signs of appendicitis other symptoms and signs which are always present. These cases formed the largest group of the series.

Group 3.—Cases 4 and 5 illustrate a group most advanced in the formation of scar tissue. In this group signs and symptoms of intestinal obstruction were superimposed on the signs and symptoms found in Groups 1 and 2.

Theory of the Causation of Hypertrophy of the Ileum beyond the Kink and of the Signs and Symptoms.

The ileo-colic artery and vein convey blood to and from the distal portion of the ileum and the first portion of the colon. They anastomose with the right colic artery and vein. The cicatrisation of the lower leaf of the mesentery of the ileum, caused by recurrent

FIG. 2.



(1) (2) (3)

Cross section of mesentery and ileum. (1) Normal; (2) scarred mesentery; (3) more advanced. Notice the shortening and thickening of the lower leaf of peritoneum of the mesentery. It also illustrates the rotation of the ileum on its longitudinal axis. The arrows indicate the same point on the ileum.

attacks of inflammation, interferes with the return flow of venous blood from the ileum beyond the kinking and therefore produces a chronic congestion in the walls of this portion of the ileum. This congestion, persisting over a period of time, causes an hypertrophy of the tissues of the ileum just as a stricture round a finger will cause an hypertrophy of the distal portion of the finger. The free anastomosis of the ileo-colic vein with the right colic vein enables the venous blood of the first part of the large bowel (but not of the ileum) to escape without causing congestion and hypertrophy of the first portion of the colon.

This interference with the circulation of the ileum causes a devitalisation of the cells of its affected portion, the degree of devitalisation depending upon the amount of interference with the circulation. The devitalisation of the cells of the ileum may produce the toxin which is absorbed by the blood stream or may upset the selective absorptive power of the diseased portion of the ileum so that it now absorbs toxic substances as well as the normal products of digestion. These toxic substances in the blood stream then act upon the different types of tissue cells with which they come in contact and so produce the various symptoms. Thus I believe the constipation found in the cases of Groups 1 and 2 is not mechanical, for the ileum proximal to the kinking is never packed with fæces. I think the constipation is due to the lethargic state of the nerves and muscles of the colon, which results from the action of the toxic substances.

The Operation.

After removal of the appendix by the right rectus incision the ileum is examined for some distance back from the cæcum. If a band of cicatricial tissue is found in the lower leaf of the mesentery this is cut completely through, great care being taken to cut every strand of scar tissue, but not to injure the subperitoneal structures of the mesentery. This removes the cause of the interference with the circulation of the ileum and the ileal kink. Nothing further was done to the mesentery, and every case healed by first intention without any signs of infection, except Case 4, and he had no signs of intraperitoneal infection.

Comment.

My reasons for regarding cicatrisation of the mesentery as the cause of the ileal kink are :—

(1) Case 2, as well as a few others in the series, had evidence of recurrent attacks of inflammation in the

appendix, but was not constipated. Nevertheless he had a marked ileal kink and scarred mesentery.

(2) Constipation, which was present in the majority of cases, was cured or greatly diminished by removing the appendix and freeing the band causing the hypertrophy. Had the "first and last kink" and not the diseased ileum been the cause of the constipation, then no relief, much less a cure, would have resulted from freeing the cicatrised band of mesentery only.

(3) The contracted scarred mesentery of the ileum, as shown in Figs. 1 and 2, in every case of the series produced the kink by pulling the ileum down, rather than by pulling it up to form an internal lateral ligament to support the cæcum, as described by Sir Arbuthnot Lane.

Failure to separate this mesenteric band when it is present is, I believe, a frequent reason why patients do not feel any better after the removal of a diseased appendix. Sometimes it is not prudent to search for this band, but, if the case permits, whenever a diseased appendix is removed this mesenteric band should be sought and dealt with if found. The thickening of the ileum, or "hypertrophy," as I have called it, is probably not a true hypertrophy. To produce this condition artificially in animals and then make physiological and histological examinations might be an interesting field for research.

Clinical and Laboratory Notes.

A NOTE ON CRETINISM, DIABETES, AND PREGNANCY.

By L. J. Witts, M.D. Manch., M.R.C.P. Lond.,
ASSISTANT TO THE MEDICAL UNIT, LONDON HOSPITAL.

THE interesting features of the following case are the occurrence of hypothyroidism in mother and daughter, and the association of cretinism, diabetes, and pregnancy in the daughter.

The mother was seen to be suffering from myxœdema when she visited the hospital with her daughter this year. She was 56 years old, and had had eight children, of whom four survive. The youngest, who later developed cretinism, was born when she was 33. At 37 the catamenia, having previously been regular, ceased. At 50 she began to get stout, felt that her memory was getting worse, and had a vague fear of something that was going to happen. She was afraid to go out by herself. The skin of the hands and feet became dry and cracked, her hair began to fall, she readily felt the cold, and the bowels were very constipated. During the last year all symptoms had become worse. She was a short, stout woman, with a pale yellow complexion and a skin that was dry and inclined to be scaly, especially on the hands and feet. The hair of the head was fine and dry, and the eyebrows thin, especially in their outer halves. The thyroid was not palpable and there were no supraclavicular pads. The only other abnormality was a mild secondary anæmia. She was treated with thyroid extract, commencing with grs. 5 a day, the dose being afterwards reduced to grs. 2. She responded well to treatment.

The daughter was admitted to hospital for menorrhagia in December, 1926, when she was 21 years old. Since 9 years of age she had been noticeably pale, with feelings of faintness and breathlessness on exertion. The catamenia commenced at the age of 19. The periods occurred every three months and lasted one to three weeks; there was some pain and the loss was excessive. There was no diabetes in the family. She was small and childlike, measuring only 4 ft. 6½ in. Her eyes and expression were dull, but she was fairly intelligent and had done book-keeping in an insurance office. She did not go out much, but read a great deal, being especially fond of Dickens and Rider Haggard. The face was broad and expressionless, the bridge of the nose poorly formed, the alæ broad, and the lips thick. The hair was short, dry, straight, and thin, and the eyebrows scanty. The complexion and the mucous membranes were pale, and the hands broad and spade-like. The skin of the whole body was dry and rough, with a thickening of the subcutaneous tissues, though not to the degree usually found in adult myxœdema. There was no pubic or axillary hair, but the breasts were well developed and the uterus was of normal size. The thyroid was not palpable. There was a severe anæmia. The Wassermann reaction in the blood was negative.

She was treated with thyroid extract, grs. 3 daily, and made steady and remarkable improvement. Her weight fell from 5 st. 6 lb. to 4 st. 11 lb., the skin became softer in texture, and the hair softer and curly. Her features became more finely chiselled, her eyes brighter, and she was much more intelligent and active in every way. Her hands became more shapely. She was discharged on the same dose of thyroid extract.

There was little growth in height, and in these last two years she has gained only 1 in. The periods occurred regularly every month, lasted about five days, and were normal in quantity. Her mental condition changed greatly. She went out to entertainments and dances and enjoyed being with members of the opposite sex. She continued very well on thyroid extract, grs. 3 daily, until September, 1927, when she was readmitted to hospital with a history of six weeks' thirst, polyuria, and weakness. The urine contained much sugar, and the blood-sugar was 0·22 per cent. She responded well to diabetic treatment and was discharged with normal blood-sugar and sugar-free urine without insulin, on a diet of carbohydrate 56, protein 53, fat 92, and calories 1264. The weight was 5 st. 11 lb.; the dose of thyroid extract was reduced to gr. 1 daily. She did not adhere strictly to the diet and often had sugar in the urine, though she became sugar-free on the same régime on readmission to hospital in April, 1928. Glycosuria and ketonuria recurred soon after discharge, and in May 10 units of insulin twice a day were prescribed with the same diet. In June she was sugar-free, but reported that she had had no menstrual period for three months. Her interest in the opposite sex had confessedly been an active one, and she was pregnant. She remained sugar-free until August when, owing to an oversight, no insulin was prescribed, though the thyroid extract was continued. On Sept. 12th she was readmitted to hospital in coma, having taken no insulin for six weeks. The blood-sugar was 0·44 per cent. In the first 24 hours she received 200 g. of carbohydrate and 200 units of insulin; in the next 24 hours carbohydrate 115, protein 14, fat 6, and 100 units of insulin. She came out of coma, the blood and urine became normal, and in a few days she was back on her usual diet. The fœtal heart was not heard. Labour commenced spontaneously on Sept. 13th, and she was delivered of a 7–8 months fœtus which showed early maceration. Her breasts secreted milk.

At present (Nov. 1st, 1928) her weight is 5 st. 11 lb. and her height 4 ft. 7½ in. The appearance is infantile but not myxœdematous. Axillary hair is absent, pubic hair is scanty, but the breasts are well developed, and she has menstruated normally again since the confinement. On a diet of carbohydrate 60, protein 55, fat 87, and calories 1243, she is sugar-free and has a blood-sugar of 0·133 per cent., with insulin 12½ units twice a day and thyroid extract grs. 2 daily. There is still a moderately severe anæmia.

Discussion.

Hypothyroidism is a great, but not an absolute, bar to pregnancy. Howard, in his study of 100 cases of myxœdema, found one in which pregnancy occurred soon after the onset of the disease and another in which it occurred at its height. The occurrence of pregnancy in this girl, who suffered also from another disease inimical to pregnancy (diabetes), is evidence of the completeness of substitution therapy. Her mother had no signs of myxœdema at the time she was born, but the early menopause four years later, at the age of 37, is suggestive. Gordon Paterson recorded the case of a woman who gave birth to cretinous children in her first two pregnancies. The first child recovered with thyroid treatment, the second died soon after birth; neither the woman nor her husband showed signs of hypothyroidism. In her third pregnancy she was treated with thyroid extract and gave birth to a healthy child. The inheritance of hypothyroidism is well established. MacIlwaine reported the case of a woman in whom myxœdema followed an attack of Graves's disease. She subsequently became pregnant. The child was normal at birth, but a year later cretinism set in after an attack of diarrhœa. Mother and child responded well to thyroid treatment. There are many examples of hypothyroidism in children of the same family. The Clinical Society's report contains several instances of myxœdema in sisters. Herrman saw two families in each of which three of the children suffered from sporadic cretinism. In both families not only were there other norma

hildren, but normal children were born between the bnormal. Herrman also noted cretinism in one of wins. Howard found that 8 out of 68 patients with ıyxœdema 11·8 per cent. gave a family history of ıyxœdema. Hun and Prudden, who reviewed 150 ases of myxœdema reported in the literature, found hat in 8 per cent. there was direct inheritance of the isease, and that in about an equal number of cases he disease occurred among brothers and sisters.

Hypothyroidism and Diabetes.

A priori one would expect the association of hypohyroidism and diabetes to be rare, for sugar tolerance s increased in hypothyroidism. Eaves and Croll ave recently published their post-mortem findings ı a cretin who died untreated at the age of 14½. 'he pancreas, though small, was proportional in ize to the body. They made a quantitative estimaion of the amount of islet tissue; normally this orms about 2 per cent. of the pancreas, but in the retin it was 3·54 per cent. This observation is upported by experiments on animals, in which the mount of islet tissue is increased after thyroidctomy. In thyroidectomised animals the amount f sugar in the fasting blood is diminished and the lood-sugar curve runs at a lower level than before he operation. The hyperglycæmia produced by a iven dose of adrenalin is less and the hypoglycæmia roduced by a given dose of insulin is greater. The oexistence of typical adult myxœdema and diabetes s still uncommon enough to be worthy of report. Nevertheless, conditions in the adult are not so clearut as in the cretin or the experimental animal. Gardiner-Hill, Brett, and Smith found the fasting level f blood-sugar within normal limits in most myxœdema ases. The blood-sugar curve was higher and more rolonged than in normal persons. Glycosuria was are, and he suggested that the renal threshold was aised. Treatment with thyroid extract did not aise the fasting level of blood-sugar in myxœdeıatous patients; its general effect was to lower he blood-sugar and to quicken the curve. I have ometimes suspected an element of hypothyroidism ı obese diabetic women at or after the menoıause and have seen patients greatly improved on reatment by undernutrition and thyroid extract—ı improvement not confined to the diabetes.

However this may be, there is no doubt of the arity of diabetes in juvenile myxœdema or cretinism. have found accounts of only five cases. Gordon quoted by Strasser) saw diabetes in two brothers, ged 3 and 4½, who were cretins; he believed that he diabetes was favourably influenced by thyroid reatment. Strasser's patient developed cretinism in nfancy and did not come under thyroid treatment ntil he was 7. He made great improvement, but year later diabetes set in and thyroid treatment vas discontinued, as it seemed to accelerate the maciation. He died 18 months later. Apert's atient was a cretinous dwarf, who measured only ·45 metres. Growth had continued up to the hirty-sixth year. At the time of Apert's paper ıe was 66 and had had diabetes for at least four ears; the urine contained about 70 g. of sugar a ay. No observations were made on the effect of hyroid treatment. Wilder's patient showed signs f diabetes at the age of 15 months. He was placed ı a strict diet which, after six months, was relaxed ithout the return of glycosuria. Hypothyroidism ppeared at the age of 3 and thyroid treatment was egun; it was discontinued on account of the return f glycosuria. During thyroid treatment growth was esumed, but after its discontinuance growth again topped and the tolerance improved so that the child ould eat anything without excreting sugar. Subsequent administration of thyroid once more caused rowth to be resumed, but only at the cost of a severe iabetes, the child continuing to excrete sugar on very low diet. It is clear that simultaneous diabetes nd cretinism led to a therapeutic impasse in preinsulin days. There are several reasons for this. he administration of thyroid extract not only raises the basal metabolism, from perhaps minus 40 per cent. to normal, but it also replaces vegetation by activity and growth, both of which mean an increased caloric requirement. The sexual system is stimulated to maturation. In Joslin's curves showing the age of onset of diabetes the peaks are at puberty and the menopause, the periods of evolution and involution of this system. Juvenile diabetes was formerly almost always fatal because of the demands made by activity, growth, and puberty. In the cretin treated with thyroid extract they are especially urgent. Nowadays, however, insulin allows us to satisfy the demands of the juvenile diabetic and enables these children to grow to maturity. The case I have reported shows that this is true also of the diabetic cretin who is receiving thyroid, and that the two forms of substitution therapy are not incompatible.

The pharmacological antagonism of thyroxin and insulin was demonstrated in the animal experiments of Burn and Marks, who found that thyroid feeding decreased the hypoglycæmic reaction to insulin. Apparently the liver became more sensitive, and therefore glycogenolysis more readily occurred when insulin was injected. I do not know that these results are absolutely comparable with clinical practice. Very large doses of thyroid were used, one animal losing nearly one-third of its weight in 20 days. From a study of the literature it appears that, although the sugar tolerance of normal subjects is fairly easily disturbed by thyroid extract, this is not likely to happen in the treatment of definite hypothyroidism. Thus the work of Gardiner-Hill, Brett, and Smith indicates that thyroid treatment does not have a harmful influence on the sugar tolerance of adult myxœdema. "Bottman found that 55 per cent. of patients with maladies other than myxœdema developed a temporary glycosuria under the experimental administration of thyroid extract. On the other hand, Scholtz, among 100 cases of cretinism, was unable to produce by thyroid administration a single case of even alimentary glycosuria" (Howard). My own experience is that thyroid extract may sometimes be of value in the treatment of obesity and *diabète gras* and, as long as symptoms of thyroid intoxication are avoided, the danger of producing or aggravating a glycosuria is not greatly to be feared.

The subject of diabetes and pregnancy has been so recently reviewed by Parsons and by Joslin that there is no need to add much on this point. "Diabetes is more menacing to pregnancy than pregnancy is to diabetes." Conception is infrequent on account of amenorrhœa, of vulvitis, vaginitis, and cervicitis, and of voluntary prevention. Before insulin at least 50 per cent. of pregnancies ended in miscarriages or stillbirths, and the mother ran a grave risk of coma at delivery, puerperal infection, or aggravation of the diabetes. Even with insulin the danger is great. The metabolism is very delicately balanced, and supervision must be close to ensure a normal delivery.

I wish to thank Prof. A. W. M. Ellis for permission to publish this case.

A SERIES OF MONSTERS.

By E. JOAN PARRY, M.R.C.S. Eng.

THE following case appears worthy of record.

A woman, aged 37, was confined in August, 1925; the child was stillborn, an anencephalic monster with a spina bifida. She was confined again in July, 1926. This was a difficult labour and the fœtal skull had to be perforated. The fœtus had a marked hydrocephalus with a hare-lip and cleft-palate. At the last confinement in July, 1927, she had twins; one was mummified, about 1 lb. in weight, and born in thick greenish fluid surrounded by the membranes. The other baby (girl) appeared perfectly normal but was premature and weighed only 3¼ lb. It developed normally.

Before her marriage this woman had four illegitimate children, all of whom were perfectly healthy. These were the only three children by the husband. In each case for the last two months of pregnancy she showed marked signs of toxæmia—œdema of legs, albuminuria. The father's blood gave a negative Wassermann.

Bristol.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS.

AT a meeting of this Section held on Feb. 1st the chair was taken by Mr. ASHLEY S. DALY, President, and a paper was read by Dr. R. D. LAWRENCE on

POST-OPERATIVE ACIDOSIS.

He began by describing the mechanisms which keep the body in the alkaline balance essential for its activities. The reaction of a fluid, he said, depended ultimately upon the hydrogen- and hydroxyl-ions in it, and was formulated by the term "pH," a negative logarithmic expression of the number of free hydrogen-ions. The neutral pH was 7 and the normal pH of the blood was 7·4. In severe acidosis the blood might have a pH of 7, which meant four or five times as much acid as normal. The chief of the "buffer substances," which kept the blood alkaline at their own expense, was sodium bicarbonate—the "alkaline reserve" of the blood. The relation between the free carbonic acid and the sodium bicarbonate was a constant of 1 : 20. Any added foreign acid was at once combined with the bicarbonate reserve, and as that was reduced the free carbonic acid had to be reduced also to maintain the constant. This was brought about by over-breathing and increased excretion of carbon dioxide through the lungs. There were many other mechanisms to counteract any acid condition; the phosphates, the proteins, and the hæmoglobin all played their part, and excess of acid was got rid of in the urine, largely neutralised by ammonia. In ketosis there accumulated in the blood and urine certain substances, of which the best known was acetone and the most important hydroxyl-butyric and diacetic acids. These were products of incomplete oxidation of fats, and might appear in the urine without any lowering of the alkali reserve; they were excreted whenever insufficient carbohydrate was being burned and were probably an expression of lack of sugar and glycogen. They appeared in normal people under conditions of starvation.

The Production of Acidosis after Operation.

Inhalation anæsthesia definitely reduced the pH of the blood within 20 minutes of induction, causing a fall in alkaline reserve, though rarely of more than ten volumes per cent. Ketonuria was much less frequent and apparently secondary to the common, slight, real acidosis. Chloroform was the greatest offender; closed ether produced acetone bodies in the urine in 89 per cent. of cases, but open ether only in 26 per cent. Ketonuria and acidosis were not, however, unknown even after spinal and local anæsthesia. Novocaine had been found to produce a small decrease in the alkaline reserve—about 5 volumes per cent.—in half the cases examined, but these were practically all abdominal operations; the condition did not occur after operations on the extremities. Ketonuria followed shock or severe fractures, and was much more common in children, women, and nervous and anxious patients. Excitement and mental shock were important ætiological factors. The mechanism of its production was difficult to explain; the factors were complex and probably multiple. Certain facts had been definitely established.

Acidosis was produced by sleep because of the insensitiveness of the respiratory centre to the stimulus of carbon dioxide. In anæsthesia the centre was still more depressed; the respiratory centre of anæsthetised dogs was not stimulated by an increase of carbon dioxide. Another factor that led to acidosis was anoxæmia. Anæsthetics produced anoxæmia by causing a slight degree of asphyxia and by reducing the blood pressure and causing slight shock. They also depressed the metabolic function of the cells and reduced their consumption of oxygen. Post-operative acidosis, therefore, was probably caused largely by the depression of the respiratory centre and of the circulation, and the resulting condition of anoxæmia. Its occurrence in local anæsthesia, however, demanded another explanatory factor. Local and spinal anæsthetics, however, were not always free from shock—mental if not physical—and it was noticeable that minor operations on the extremities were not followed by acidosis. Ketosis was easier to explain than real acidosis. It depended on a temporary upset of carbohydrate metabolism, and all forms of inhalation anæsthesia raised the blood-sugar, sometimes causing glycosuria. This was because the glycogen store of the liver was rather quickly depleted by anæsthetics, and so the metabolism changed over from carbohydrate to protein and fat, and ketone bodies were produced. Protein metabolism meant further production of acids, which in its turn reduced the alkaline reserve. Insulin action was always defective in conditions of acidity. Adrenalin also disturbed the carbohydrate metabolism and raised the blood-sugar, and there was increased output of adrenalin in excitement, shock, and anxiety.

The Control of Acidosis.

It had long been known that the tendency to ketosis after operations could be stopped by giving plenty of carbohydrates. Neither these nor alkalies, however, prevented the slight fall in the alkaline reserve, which was most difficult to control. In normal individuals it was of no importance at all; it did not cause chronic symptoms or vomiting. It could not be prevented with certainty by any preparation of the patient, although the administration of glucose and insulin was the most likely method to succeed. If the patient had established ketosis or acidosis before the operation efforts should be made to protect him. Those who had acidosis without ketonuria were mostly chronic nephritics or sufferers from wasting diseases. They were difficult to recognise without chemical tests, but operative procedures were avoided on them for other reasons. If they must be subjected to operation the anæsthetic should be spinal or local if possible and they should be prepared by a moderate dose of sodium bicarbonate—e.g., eight drachms a day for a few days—and an abundant carbohydrate diet.

Those who had ketonuria without any real acidosis were both more common and more important. Most often acetone bodies were present in the urine without any real acidosis, but if they were present in large amount it might mean that the alkaline reserve was reduced. In these patients an operation, with the resulting increased ketosis, might lead to headache, nausea, vomiting, and depression, or even liver damage—especially if sepsis were present. A liver without its normal store of glycogen was much more sensitive to the toxic action of chloroform and ether. The presence of ketone bodies in the urine in such cases constituted a danger-signal which should not be ignored. Among non-diabetics pregnant women were especially liable to this danger, and children more

han adults. The significance of the ketone bodies lepended on their quantity. If only the nitroprusside est were positive, small amounts were present; a positive ferric chloride test meant serious if not langerous quantities. The operation should be postponed until the ketone bodies had been got rid of by a liberal carbohydrate diet, which usually took 24 or perhaps 48 hours. There was no point in giving insulin to the non-diabetic, as the sugar stimulated insulin production from his own pancreas. If the ketosis were severe and the patient very toxic the sugar might not provoke the adequate response, and in that case insulin should be given along with it. If the case were an emergency and the operation could not be postponed spinal or local anæsthesia should be used. Gas and oxygen with a minimum of ether was the next best, and chloroform should be avoided. Glucose must be got into the system as soon as possible—50 g. by mouth if the patient could take it—and rectal administration during and after the operation. If the degree of ketosis were not great this would be sufficient. If, however, the ferric chloride test were positive the situation was serious; 50 g. of glucose with abundance of saline should be given intravenously, together with 20 units of insulin, before the operation, followed up with rectal glucose. If the alkaline reserve were known to be low six or eight drachms of sodium bicarbonate should be added to the intravenous dose; not more, for overdosage had grave depressing results.

All operations tended to make diabetics worse, causing severe ketosis and acidosis, perhaps coma. As good a supply of glycogen in the liver as possible should be secured by giving them more carbohydrate than usual and considerable amounts of insulin. If, however, there was time to prepare them properly diabetics could go on the table as normal operative risks. It was as well in addition to give 20 units of insulin and an ounce or an ounce and a half of sugar an hour and a half before the operation. The best dose could only be established by a blood-sugar estimation, but if this were unobtainable in an emergency 20 units of insulin and 20 g. of sugar should be given before the operation and repeated four-hourly after it. If there were not much sugar in the urine, or it rapidly disappeared, the sugar-dose should be twice that of the insulin. In severe cases these doses might, of course, be quite inadequate. Diabetics did well under gas and oxygen and ether, but the spinal method was the better one for them.

Discussion.

Dr. P. J. CAMMIDGE suggested that Dr. Lawrence might have laid more stress on the ultimate cause of acidosis in the chemical composition of the tissues rather than of the blood. The cells of the body were like chemical batteries, and alteration in the concentration of the chemicals in them meant alteration in the current. There might be an alteration in the alkali reserve without symptoms, or symptoms might appear without any alteration in the reserve. Another factor was variation in the amount of water retained by the tissues. Alteration of the proportion of the electrolytes in the cells meant alteration in their volume of water. The causes of acidosis might be divided into distinct groups: (1) anhydræmia, as produced by vomiting, diarrhœa, and polyuria; (2) over-production of the normal acid products in the body—lactic, phosphoric, sulphuric—as in nephritics; (3) removal of the alkaline bases of the cells—this also acted in nephritics, because the damaged kidney could not produce the ammonia required to neutralise these acids and so had to use bases; (4) the formation of abnormal acids, as in diabetes; and (5) changes in the osmotic pressure between cells and plasma. Whether these changes produced acidosis or alkalosis depended on how they were brought about. It did not necessarily follow that because a patient had the symptoms of acidosis that he had actual acidosis; he might have alkalosis, which was not at all rare after operations and was recognised by the absence of chlorides from the urine. If the chlorides were low it was advisable to give salt intravenously with glucose. It was important to recognise the child who suffered from cyclical vomiting and to give carbohydrate before any operation. These children had inherited, as a Mendelian dominant, a liver that could not store glycogen normally. Oatmeal cooked for five or six hours was preferable to glucose, especially for children; it contained a molecule that the liver utilised more effectively than any other.

Prof. E. C. DODDS said that in his experience post-operative acidosis was very rare indeed, and asked for a definition of it from the anæsthetist's point of view, as the clinical definition was most important. He asked why it was that women in childbirth stood chloroform so well.

Mr. F. E. SHIPWAY said that anæsthetists would all agree that this was a laboratory problem and very rare in practice. Chloroform was not good for pregnant women who were having surgical operations, but the anæsthesia used in childbirth was very light. Only deep chloroform anæsthesia caused acidosis.

Dr. KINGSTON BARTON pointed out that the woman in labour was breathing deeply and rapidly, and so could take chloroform with impunity.

Mr. ZACHARY COPE described a case of post-operative acidosis clinically, but said that he had not seen one since chloroform had been abandoned for abdominal operations.

Mr. C. H. HUGHES said that all surgical cases should have their urine examined for ketone bodies.

Mr. R. E. APPERLY recalled the first cases of delayed chloroform poisoning described from Paddington Green Children's Hospital. Most of them had had a very short anæsthetic. His experiments on animals had confirmed the suggestion that it was short, deep chloroform administration that was dangerous.

Dr. J. BLOMFIELD pointed out that some of the early cases at Great Ormond-street had had very short ethyl chloride anæsthesia. The condition was not seen now that chloroform was little used.

The PRESIDENT said that the only fatal case he had seen had been after a very short anæsthetic, and asked how to treat a patient with cyclical vomiting at an emergency operation.

Reply.

Dr. LAWRENCE said that if there was an hour to spare the child should have an ounce of glucose by the mouth; if there was no time intravenous glucose should be given during the operation, and if the child were very toxic ten units of insulin could be added. Acidosis had very little to do with grave post-operative toxæmia, the toxins of which were quite different, although always associated with ketone bodies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society took place at the House of the Medical Society of London on Jan. 25th, Dr. DAVID NABARRO occupying the chair. The subject of discussion was the

TREATMENT OF GENERAL PARALYSIS OF THE INSANE BY PYROTHERAPY.

Dr. W. D. NICOL opened the debate. He said that at the Horton Mental Hospital the patients were certified before being admitted. Usually the diagnosis of general paralysis did not present many difficulties. A matter of great importance was the physical condition of the patient, since the severe malarial attack was liable to test his strength considerably. While early cases showed most favourable results, advanced cases also could safely be treated by this method, provided that physical examination revealed no definite organic disease, especially in the circulatory and renal systems. Septic foci in the teeth and the alimentary system should be dealt with before commencing the malaria treatment. At Horton, by arrangement with the Ministry of Health and the London County Council, a special block was set aside for treatment by malaria. The stage of

development of the parasite must be sufficiently advanced, so that when the mosquito bit it will be effective. The incubation period varied from 10 to 14 days, and it was important that no untoward event should happen during that time. The patient was put on a four-hourly temperature chart from the eighth day of the infection onwards; and routine blood examination dated from the first febrile manifestation. During the initial stage the symptoms resembled those in a commencing attack of typhoid fever, though the temperature was more "spiky" in character. In the developed stage the parasites could easily be seen in films of the blood, and during the first few days their numbers increased.

Dr. Nicol regarded as the most important procedure in the treatment the temporary interruption of the course of the fever, since this was one of the biggest factors in reducing mortality from induced malaria. The indications for this temporary interruption were a heavy parasite count, persistent vomiting, fainting, cyanosis, and so forth. Ten to 12 paroxysms of fever should be aimed at, after which the attack could be terminated by quinine, small doses being just as effective for this purpose as large ones. After treatment, as the patient was left anæmic he should be given an iron tonic. As to results, it was found that about one-third of the patients were so improved physically and mentally that they could be discharged; one-third were improved physically, but not sufficient mental change was apparent to justify discharge; while the remaining third showed no change for the better, but progressive deterioration. The sooner general paralysis of the insane was diagnosed the better chance had this treatment of bringing about recovery. In mental hospitals, where cases were not admitted until certified, there was necessarily delay in instituting the treatment, and this was regrettable.

T.A.B. Vaccine.

Dr. J. M. MACKENZIE said that many general paralytics suffered from chronic sepsis in addition to syphilis, and the sepsis might be responsible for at least some of the more acute symptoms, such as restless motor excitement with destructiveness. Glaessner had found that cases of enteric fever showed a striking immunity to influenza, and for this and other reasons it was decided at Rubery Hill Mental Hospital, Birmingham, to try the effect of T.A.B. vaccine. Injections with a B. & W. product were given intravenously each day for ten days, starting with a dose of 300 million total organisms, gradually increased to 6000 millions. After a six-weeks' interval a second course of ten injections was given, this time commencing with 1500 and rising to 20,000 millions. During the interval four injections of 0·45 g. of N.A.B. were administered. Six weeks later, after four more injections of 0·45 g. N.A.B., a third course of T.A.B. similar to the second course was given in some cases. Half an hour after each injection a severe rigor began, the peak being reached in two hours. Herpes occurred on the fifth day. Usually the temperature dropped to normal within 12 hours of the injection. If that drop did not occur a septic focus should be searched for. The best results were obtained in grandiose and restless cases. Usually there was a return of the excitement after pyrogenic treatment had ceased, but the tendency to do impulsive acts was replaced, in the majority of the patients, by the ability to do useful work under supervision; in a few initiative returned. During each course of injections there occurred a fall in the body-weight, but it was well regained in the intervals, and muscle tone was improved. There seemed to be no direct connexion between serological changes in the blood and change in the mental and physical condition of the patient. These T.A.B. vaccine injections, however, caused remission in the course of general paralysis, and in the series under Dr. Mackenzie's observation this remission extended in some patients to two and a half years, but was as short as four months in a few. Incidentally, the treatment conferred a high degree of immunity to the typhoid group of infections, provided a six-weeks' interval elapsed between each course of fever-therapy, to guard against possible exhaustion of the antibody-producing mechanisms.

With regard to end-results, by this treatment life was prolonged; during the remission the patients were quiet and amenable, and might be able to do useful work. The question of their discharge from the mental hospital was always a difficult one, and much depended on what sort of home life they were likely to have.

Discussion.

The CHAIRMAN referred to cases at Great Ormond-street Hospital for Sick Children, showing symptoms of what was termed general paralysis of the insane, though the condition in children was difficult to diagnose owing to the absence of grandiose symptoms. Fifteen cases had had malaria treatment, all except one being congenital syphilitics. Half the number were treated by mosquito bite, the others by the injection of blood from malaria cases; the incubation period varied according to which method was employed. In children the temperature shot up at once after the injection, in contrast with the gradual rise in adults mentioned by Dr. Nicol. Dr. Nabarro was not very satisfied with the general effect of this treatment in children.

Dr. WANSEY BAYLY said that many observers regarded it as dangerous to give this treatment to advanced cases; his own view was that any risk was justifiable in an established case, since it was not of tragic moment even if death happened to be hastened.

Dr. H. M. HANSCHELL thought that every patient with general paralysis of the insane should be treated with malaria, certainly every one whose cerebro-spinal fluid was Wassermann positive. He had used T.A.B. in the way described for disseminated sclerosis eight years previously, and during the last two years for latent tertiary cases of syphilis, and had thus obtained a negative Wassermann.

Dr. BUCKLEY SHARPE said that in children it was very difficult to be certain whether relapse had occurred, because they were so liable to chills and incidental illnesses.

Dr. NICOL and Dr. MACKENZIE briefly replied.

New Inventions.

NEW NEEDLE FOR THE INJECTION OF VARICOSE VEINS.

THE two main essentials for the successful treatment of varicose veins by the injection method are that the solution shall be brought into as close contact with the endothelium as possible and at its highest concentration. This needle has been designed for the purpose of meeting these desiderata by the direction given to the flow as it leaves the eye, which being laterally placed, permits of the solution being injected at an obtuse angle to the wall of the vein. There is less danger of the solution being injected into the wall of the vein instead of into the lumen, owing to the very short bevel and the distance from it to the eye of the needle. With an ordinary hypodermic needle this is liable to happen, especially so with a long-pointed bevel. Owing to the position of the eye, there is less likelihood of it being blocked as it penetrates the tissues to enter the vein. Finally, any direction may be given to the flow by axial rotation of the syringe. The lettering REGD. stamped on the mount should be noted, as it indicates the direction of the eye in relation to the walls of the vein, so that it is possible to make a complete ring around the wall with the sclerosing solution. This method will be found useful in treating very dilated veins. The needles are made by Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, W. 1.

Reviews and Notices of Books.

THE ART OF SURGERY.

By H. S. SOUTTAR, D.M., M.Ch. Oxf., F.R.C.S. Eng., Surgeon, London Hospital. London: William Heinemann (Medical Books) Ltd. 1929. Pp. 624. 30*s*.

THIS book is written with the avowed object of lightening the student's labour by omitting what is not essential and by describing very fully what is fundamental. It bears little resemblance to the conventional text-book, though the general arrangement of the contents follows the usual pattern, commencing with inflammation, suppuration, tuberculosis, syphilis, gangrene, tumours, hæmorrhage, and other general surgical subjects, and proceeding to regional surgery. Apart from its arrangement the text does not resemble that of any ordinary text-book; there is a greater continuity in the method of writing, which makes for pleasant reading and there does not seem to be such a large and forbidding collection of facts to be absorbed by the reader. This effect has not been obtained by the omission of any material facts, but partly by the skill of the writer and partly by his resolve to avoid too much detail. Many text-books consist of a blend of the author's personal experience of surgery with facts obtained from other text-books or original writings, and the younger the author the more do the latter tend to predominate. Mr. Souttar has relied entirely on his own knowledge and the fruits of his wide experience. Results have justified this method; those facts which have seemed to Mr. Souttar to be of great importance are undoubtedly those which should first be absorbed by the student, who can later supplement this fundamental knowledge from the study of more advanced works or special monographs. A possible danger in a text-book by one author is the statement of only one point of view on a controversial subject, but on the whole this pitfall has been avoided by Mr. Souttar with excellent judgment. An exception is in the section on paralytic ileus and peritonitis, where Mr. Souttar omits to mention that there is a definite school of thought favouring absolute rest to the intestines. He describes only the vigorous treatment pursued by the opposing school. Similarly, his enthusiasm for gastro-enterostomy in the treatment of chronic gastric ulcer is not universally shared, while his assumption that the hopes formerly held as to the value of medical treatment have now been abandoned is certainly not in accordance with modern views.

It is difficult to select any chapter for special comment since the book is remarkably uniform in aim and value. Even to those subjects in which his previous contributions to surgical literature show him to be specially interested, Mr. Souttar gives only their just proportion of space. The section on fractures is typical. The writer of a surgical text-book is always hampered by tradition when he writes on this subject since he feels it to be his duty to deal minutely with fractures which rarely if ever occur and splints and appliances which are of historical interest only. Mr. Souttar has broken away from the traditional method, for he discusses only those fractures of each bone which are common, giving the physical signs and the points specially to be noticed. He then describes a method of treatment which has given good results in his hands and should give equally good results if proper care is taken in all cases. The number of splints recommended is small, but most surgeons will agree that it is possible to treat most fractures with those mentioned, and it is indisputable that it is better for the student to understand thoroughly the way to apply a small number of splints than to have a fragmentary knowledge of many. There is certainly no ground here for the common complaint that the chapter on fractures is the most boring part in a surgical text-book.

As would be expected, the chapters on injuries to nerves, cerebral injuries and tumours, and diseases of the œsophagus are all excellent. Especially in the surgery of the nervous system it is difficult to separate the essentials necessary for the student from the refinements required by the expert, and Mr. Souttar has drawn the dividing line with skill. Although he is well known as an inventor of ingenious surgical instruments, he makes no more than a modest passing reference to some of his inventions, in accordance with his determination to avoid any details of operative surgery. He has thereby preserved the balance of his book, but we should have liked to see an illustration of his craniotome, an instrument of the greatest mechanical beauty and precision. There should also have been some reference to the useful metal frame devised by him for the support of splints used in fractures of the lower limb. This frame is much less cumbersome than the Balkan frame. The last chapter is devoted to a short but excellent description of local and spinal anæsthesia. The general principles are stated clearly and their application in several situations fully explained. As the author points out, this method of anæsthesia is limited only by the skill and anatomical knowledge of any surgeon who has thoroughly grasped the general principles. There are two useful appendices, one concerned with the measurements of the lower limb and the mechanics of apparent lengthening and shortening, always a confusing subject, and the other with the use of radium.

The book is most attractively produced. It is a moderately large and pleasant volume which is not too heavy to hold for a long period; it stays open easily and the pages lie flat; the paper is good and not highly glazed, and the printing is from a sound type and easy to read. A conspicuous feature is the very wide margin on the outer side of each page; this has not only a decorative effect, but it has also the more important function of providing space for sub-titles and illustrations which look casual, but are original in style and peculiarly apposite to the text. They are reproduced from drawings which are admirably chosen. No explanatory legends are required, for each drawing is accurately placed next to the paragraph which it illuminates. Mr. Souttar's ideal was to provide a thumb-nail sketch for each paragraph capable of being illustrated. He has already gone far towards reaching this end and we look forward in each succeeding edition to seeing interesting sketches in the still empty margins. We have no doubts as to the success of this production.

BACTERIOLOGY.

Recent Advances in Bacteriology and the Study of the Infections. By J. HENRY DIBLE, M.B. Glasg., M.R.C.P., Professor of Pathology and Bacteriology in the Welsh National School of Medicine; late Professor of Pathology in the University of London. London: J. and A. Churchill. 1929. Pp. 363. 12*s*. 6*d*.

IT is the misfortune of bacteriology that it has been chiefly studied by medical men in its relation to diseases, especially those of human beings. It has thus been very much an applied science and has suffered in consequence. In recent years, however, there has been a greater tendency to study the organism for its own sake and not merely for its effects upon a host; bacteriology has, in fact, developed a definitely academic side. This in itself is satisfactory, but it does not lighten the work of the medical student, who has not only to keep himself abreast of the increasing knowledge of the influence of bacteria in disease, but is also expected to have some idea of the highly complicated problems of pure bacteriology. And who is to tell him how much of this academic knowledge it is necessary for him to acquire? Prof. Dible has attacked the problem with success, and has written a book which should have a wide appeal not only to students and medical practitioners who are not especially versed in bacteriology, but also to those whose knowledge is more intimate. The book is divided into 27 chapters dealing with different aspects of the subject. Some of these are

related to one another, but the arrangement seems more or less haphazard; the pneumococci, for example, are sandwiched between measles and tularæmia and the spirochætal infections. Smooth progression from chapter to chapter is, of course, impossible in a work of this kind.

One of the earlier chapters, that on the streptococcus problem, is probably the best in the book; it deals in the most comprehensive way with this important subject. The author can scarcely be blamed if the next chapter on bacterial variations is not quite so clear and good; he has done all that is possible in the present confused state of roughs and smooths, and O's and H's. An excellent chapter on the bacteriophage is followed by two others, we rejoice to see, on experimental epidemiology, and Calmette and B.C.G. The next three chapters are devoted to filterable viruses, and the most important examples of these are well surveyed, though perhaps the treatment of the infective theory of malignant disease leave something to be desired. Other chapters deal with Rickettsia bodies, measles, pneumococci, spirochætal infections, local immunity, diphtheria, and anaerobic organisms. The book is well printed and produced, but the table on pages 2 and 3 is far from easy to read.

To write single-handed a review of recent work on bacteriology is no easy task, but Prof. Dible has succeeded admirably. He has surveyed the ground with thoroughness, and has exercised excellent judgment in the presentation of conflicting views. His book will not be the least popular member of this excellent series.

THE MOTOR MECHANISM OF PLANTS.

By Sir J. C. BOSE. London: Longmans, Green and Co., Ltd. 1928. Pp. 429. With 242 text-figures. 21*s*.

THE veteran founder of the Bose Research Institute in Calcutta gives in this volume a further series of his ingenious researches, showing that all plants respond to stimulation by movements of various kinds, similar in kind to, though less in degree than, those of the special "sensitive" kinds. He also deals with the existence of a mechanism for pumping sap which is subject to peristaltic movements akin to those of the mammalian bowel. Those people, especially who in their youth learnt botany and zoology as separate subjects and not as part of a considered scheme of training in biology, will be stirred by this account of the resemblances between the animal and the vegetable kingdom.

ELEMENTARY HÆMATOLOGY.

By W. E. COOKE, M.D., Director of the Pathological Department, Royal Infirmary, Wigan. London: Charles Griffin and Co., Ltd. 1928. Pp. 100. 7*s*. 6*d*.

As its name implies this book is concerned with the elementary facts of hæmatology, which are set out in a most satisfactory way; the language is lucid and the illustrations, most of which are from microphotographs, are clear and instructive. The descriptions of the various "blood" diseases are short but full enough to give a distinct picture; the section on the purpuras is remarkably good, and may be recommended to students of the blood who have passed the elementary stage. The book should prove popular with students and with practitioners who wish to keep at least within hailing distance of modern work.

GREEK THOUGHT.

By LÉON ROBIN. London: Kegan Paul, Trench, Trübner and Co. 1928. Pp. 409. 20*s*.

Prof. Léon Robin, Professor at the Faculty of Letters of the University of Paris, contributes the latest volume to the History of Civilisation, edited by Mr. C. K. Ogden, of which some 50 volumes are now in circulation. The volume has been translated from a revised and corrected French edition by Mr. M. R. Dobie.

From the medical point of view the evolution of the scientific spirit, as developed by the Greeks and exposed by Prof. Robin, has no very direct connexion with medicine, and when we say that in this long and closely written book the allusions to Hippocrates are but two or three in number and that those are brief and indirect, it will be seen that the work must not be confused with any history of the actual practice of medicine and surgery, as it existed in the four or five centuries preceding the Christian era or in the subsequent Roman period. Prof. Robin's learned pages, however, supply a general background to such a history, for he details the story of the great schools of Greek thought, and gives pictures of the philosophers connected with them, showing the connexion of their teaching with the external circumstances of the time.

An interesting foreword is supplied by Mr. Henri Berr, in which he points out that, although Prof. Robin presents philosophy and science in their constant relationship, he draws a distinction between the history of the one and that of the other which it is not easy to recognise. This reflection is founded upon Prof. Robin's statement that the history of philosophy is philosophy, and has for the philosopher an ever-living interest, while the history of science is not science, but only the dead part of scientific effort towards truth, the effort being forgotten when the end has been reached. This would imply that the history of science can only satisfy the curiosity of the erudite, and not, like the history of philosophy, the general and deep needs of society. This view Mr. Berr controverts, for he finds that the history of science not only shows the mind adapting itself to things and man taking possession of his environment, but it makes us follow the constitution of a method intended to solve the problems which the mind sets itself, and which it formerly tried to decide first in religion and then in metaphysics. Every medical man will take this view, which, in other words, finds science to be an instrument for solving philosophic problems; and the science of medicine in its modern manifestations is increasingly being shaped in this direction, in spite of the apparent divorce of the special sciences from philosophy.

The book forms a valuable section in this important historic series, but it makes quite difficult reading. In many places readers, save those specially equipped, will find a Greek lexicon necessary in spite of the occasional translation of terms and quotations, although familiarity with the original texts quoted from is not necessary for the comprehension of the arguments, and could not be expected from any save accomplished classical scholars.

DISEASE OF THE LOCOMOTOR SYSTEM.

Differentialdiagnostik der Inneren Krankheiten des Bewegungsapparates. By Dr. ERNST FREUND, Privat Dozent in the University of Vienna; and Dr. ALBERT SIMO, Bad Schallerbach (O.-Ö.). Dresden and Leipzig: Theodor Steinkopff. 1929. Pp. 58. M.4.50.

THIS fasciculus of a larger work ("Praktische Differential-Diagnostik für Ärzte und Studierende") treats of the differential diagnosis of internal diseases of the mechanisms of movement. In the introduction it is stated that the local manifestations of general diseases such as those of the nervous system, of the metabolic system, and the endocrine glands, are often to be observed in the organs of movement. The subject matter is considered under three headings: (1) the general diseases of the apparatus of movement such as acute polyarthritis, pains, and polyarthritis without fever; (2) the spinal column and various pains and their significance and occupation neuroses; and (3) in the lower extremity, limping, swelling of the knee-joint, and pains in various regions.

It will thus be seen that this booklet is an illustrated guide to the significance of various symptoms which appear in the limbs and particularly of the diagnostic value of painful sensations. It should be useful to the student and practitioner.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 9, 1929.

SPINAL ANÆSTHESIA.

THE birth of spinal anæsthesia occurred some thirty years ago when Prof. BIER, of Kiel, published the results of some experiments in which, for surgical purposes, he had introduced cocaine into the spinal canal. The method was sufficiently startling in its results to attract considerable attention. TUFFIER in France became interested, as did a number of surgeons scattered throughout the world. Soon, however, unpleasant concomitant and after-effects were observed to occur distressingly often, nor could their appearance be prevented by any precautions in technique. Spinal anæsthesia was abandoned except by a few enthusiastic workers who held strongly the conviction that in principle it was sound and must be capable of further development. Much of the difficulty lay in the fact that cocaine is a very toxic agent. When less dangerous drugs such as tropacocaine and stovaine became available interest in spinal anæsthesia was renewed. In this country valuable investigations were made in 1907 by A. E. BARKER, who was able to bring forward a series of cases where the advantages of lumbar anæsthesia were manifest. BARKER demonstrated first how a heavy anæsthetic solution could be made to assume that position in the spinal canal which was necessary so that the anæsthesia might spread to the upper abdomen. JONNESCO in 1909, by high injections, extended its use to operations upon the thorax, head, and neck. But because the physiology of the procedure was not well understood accidents still occurred which marred the brilliancy of the successful results, and led once more to a diminution of interest in the method. Hence until quite recently spinal anæsthesia occupied a very small place in the technique of most modern operating clinics, and when used at all it was reserved for operations upon the lower limbs. In the early stages of the war it was hoped that spinal anæsthesia would be of great assistance in combating the shock of serious wounds of the lower extremities, but soon it was asserted that shock was a contra-indication and another check to its popularity occurred.

It is really only since the war that attention has again been directed to the method particularly in connexion with the growing popularity of novocaine, which is the least toxic of all known local anæsthetics. Knowledge of the mode of action has accumulated, and a technique based on the use of novocaine, with the precautions which we have learnt to respect, has resulted in a striking diminution in the incidence of untoward accidents. On page 271 of this issue we publish a Hunterian lecture by Prof. C. A. PANNETT which deals with the use of spinal anæsthesia for operations upon the upper abdomen. Whilst for this purpose it is not so implicitly reliable as inhalation anæsthesia, it does promise very great advantages to the patient. It seems probable that before long spinal anæsthesia will be made as efficient and safe as general anæsthesia is to-day. The dreaded fall of blood pressure is not so much to be feared now that the mechanism of its production is known and that measures can be taken to combat it; the risk of permanent paralysis is negligible if novocaine be used and puncture takes place below the level of the cord; ocular paralyses are transient and have become progressively rarer; even the severe headache following operation is much less frequent with the modern technique, where a very fine needle is used for the injection. Inhalation anæsthesia, moreover, is not without its inconveniences. The patients who are given spinal injections are at least free from post-operative disturbances, are more comfortable in the days immediately following operation, and are immune from the late often very serious sequelæ associated with general anæsthesia. Intensive study designed towards the elaboration of a more perfect technique of spinal anæsthesia for general application is being pursued in America, where surgeons are seeking escape from the disadvantages of ether narcosis. Particularly valuable work has been done by G. P. PITKIN and F. C. MCCORMACK and H. KOSTER. This last observer has applied the technique to the whole body so that operations upon the head, neck, and upper limbs can be performed as freely as upon the lower extremities. In this he has followed LE FILLIÂTRE, who nine years ago advocated general spinal anæsthesia with cocaine. It was LE FILLIÂTRE who first introduced the method of reducing cerebro-spinal pressure before injection by removing definite volumes of cerebro-spinal fluid. His methods are drastic, consisting of the removal of 25–30 c.cm. of fluid and the forcible injection through a needle of large bore of 2·5 to 3 c.cm. of a 2 per cent. solution of cocaine hydrochloride. He was recently able[1] to report nearly 10,000 cases with only two deaths, though it must be admitted that few surgeons have been so successful and free from accident.

The development of anæsthesia by the spinal route is likely to be important. It should be emphasised, however, that caution is necessary and that inexperienced persons should study the story of failures as well as the list of successes before plunging into the spinal canal a needle of large bore filled with a highly toxic preparation. It would be unfortunate if for the third time a very valuable procedure should fall into disrepute.

CONTRIBUTIONS TO HOSPITALS.

TWO interesting cases have recently occurred in which the law has indirectly discouraged the gift of money to a hospital. In the first, the firm of BOURNE and HOLLINGSWORTH was refused permission to deduct a contribution to the Middlesex Hospital as a business expense in computing profits for purpose of income-tax. The firm's claim was not unreasonable. Since 1908 it had maintained two private hostels for its women employees and one for its men. A private nurse was kept at each and a doctor attended daily, but in cases of serious illness the members of the firm's staff were sent to the hospital. The hostels cost more than £1000 a year to maintain; if the company treated all serious cases under its own arrangements without sending them to the hospital the additional cost would be more than 1000 guineas. From 1904 to 1918 the firm had subscribed annual

[1] La Presse Médicale, 1928, xxxvi., 1320.

sums of an increasing amount to the Middlesex Hospital. In 1919 and 1920 an additional 1000 guineas was given. In 1921 and subsequent years the subscription was 100 guineas; in 1926 the company added a subscription of 4000 guineas. The extra sums in 1919 and 1920 were made because it was felt that there was an accumulated liability to the hospital on account of the frequent use made of it by the firm's employees during the war. The firm took a very proper view of its responsibilities for its employees and had an understanding (though not, of course, a binding agreement) with the hospital that none of its employees would be refused admission. From the firm's point of view, therefore, the subscriptions were a quid pro quo, a proper business expense and an admissible deduction as being (under the Income Tax Act Rules) money wholly and exclusively laid out or expended for the purposes of its trade. The claim was for deduction of the sums subscribed in 1919 and 1920, and it appeared that the Commissioners of Inland Revenue had actually allowed a subscription of 50 guineas as a business expense. The Inland Revenue, however, argued that this was a concession, not a legal right; alternatively, so ran the argument, the large sums subscribed in 1919 and 1920 were not wholly and exclusively laid out for the purposes of trade in relation to those particular years, because the subscriptions were intended to make up deficiencies for previous years. The Special Commissioners held that there was no legal right to make the deduction, and Mr. Justice ROWLATT agreed with them. He remarked, however, that if the Special Commissioners had taken the opposite view of the question of fact he would not have dreamt of disturbing their decision. On a question of fact the Commissioners' decisions are hard to shake. Counsel for the firm essayed to treat the matter as one of law not of fact, by submitting that the Commissioners had misdirected themselves in law by deciding that a hospital subscription could never be an allowable deduction. This view the judge was unable to accept; the upshot is that, to the extent of the taxation upon the amount subscribed, a hospital subscriber has been penalised. Whether the firm merely decided to show gratitude for hospital services rendered or whether the arrangement could be viewed as a simple, though informal, working agreement, the result is the same.

The second case in which the gift of money to a hospital was unfortunately discouraged by the law occurred at the Liverpool Assizes on Jan. 31st. In awarding some £3000 to a man injured by a motorist's negligence, the jury recommended that, if possible, there should be a further sum of £50 paid to the Stanley Hospital where the plaintiff had had 13 weeks' treatment. Mr. Justice WRIGHT pointed out that he had no power to award damages to anyone but the plaintiff. Counsel suggested that the jury might have awarded the sum to the plaintiff to be paid to the hospital for operations performed, but the judge replied that no such condition could be imposed. Hospitals, he said, have extraordinary hardships in having to deal with injuries, often serious, sustained by members of the public after being run into by motor-cars. "There ought to be some means by which they could be reimbursed; as a rule, the costs of the hospital are not included in damages at all, and the hospital has no claim." Hospitals might, he added, send in a bill to the unfortunate sufferer, and he might include that bill in his claim for damages. "It is certainly a matter which ought to be considered by the proper authorities." The learned judge presumably meant that Parliament should be asked to pass something of the nature of a Hospitals (Payment for Treatment) Bill, to provide that where a plaintiff recovers damages for personal injuries due to negligence, such damages may include sums reasonably paid or promised to a hospital for treatment in respect of such injuries. The companies which insure motorists against third party risks might object that the Bill would impose a burden on them; but at present their policy-holders are trading on the charity of the hospitals.

CONCENTRATED ANTITOXIN.

SOON after the introduction of diphtheria antitoxin 30 years ago, medical men began to inquire whether it would not be possible to obtain antitoxic serum of higher potency so that a large dose of antitoxin could be administered in small volume and that at the same time the incidence of "serum sickness" with its troublesome train of urticaria, malaise, and arthralgia might be lowered. Dried serum appeared to promise stability, and search was made for a reliable preparation of dry material which might be dissolved in a small volume of water when required for injection. Dried serum, however, was apt to become partly insoluble and the solution or suspension in water was not always limpid. This method of providing antitoxin has now fallen almost entirely into disuse except for isolated communities. But when E. P. PICK and his co-workers showed in 1902 that most of the antitoxin was attached to a certain easily separable fraction of the total protein in serum the possibility of concentrating serum by discarding the useless protein arose and was welcomed by serologists. When ammonium sulphate is added to serum to about one-third the saturation point, a precipitate is formed which is insoluble in water free of salts. This "euglobulin," when redissolved in saline solution, contains practically no antitoxin nor does albumin, which is precipitated by between half and full saturation with ammonium sulphate. The middle fraction, however, termed "pseudo-globulin," precipitated by ammonium sulphate between one-third and half saturation, and soluble in water or in saturated solution of sodium chloride, contains almost the whole of the antitoxin. The modern processes of "concentration" or purification, arising largely from the work of R. B. GIBSON and E. J. BANZHAF, are based on the application of these characteristic solubilities. The euglobulin and albumin, containing no antitoxin, are removed by fractional salt precipitation or by methods of electro-dialysis, and the pseudo-globulin, rich in antitoxin, is retained. By these processes concentrated antitoxin is produced which, for each unit of protein present, contains from two to three times as much antitoxin as the original serum. The concentration per cubic centimetre obviously depends on the protein percentage in the final fluid provided. It is found that with a protein percentage higher than 20—the limit under various official regulations—the fluid is undesirably viscous. In America, for many years past and, more recently in England, concentrated diphtheria and tetanus antitoxins have been in routine use. Concentrated or purified serum has now made its appearance in other European countries, though we understand that in Germany none of the antitoxins subject to control may be issued as serum concentrated with ammonium sulphate.

Various objections to the adoption of concentrated serum have been brought forward. During concentration, it has been said, certain curative bodies

f unknown composition are lost, and, therefore, nconcentrated serum has a more rapid and thorough ıfluence in diphtheria than does concentrated serum ontaining the same number of units; moreover, oubt has been thrown on the rapidity of absorption f concentrated serum compared with natural serum. IETSCH and BIELING,[1] working with serum con-entrated by evaporation, concluded that this serum as absorbed less readily than natural antitoxic erum, but the careful experiments of W. H. PARK nd colleagues appear to supply strong evidence hat this is not true of ordinary concentrated serum. linical experience in England does not confirm the bjections; medical superintendents of isolation ospitals, who have had ample opportunities of omparing natural and concentrated antitoxin, have, uring the past ten years, gradually transferred their avour to concentrated serum, and this is now used lmost universally. The change is the more impressive ı that concentrated serum formerly cost hospitals onsiderably more for a given number of units, and ; yields far less profit to the manufacturer. The atient's interests have, however, triumphed over hese objections, and the incidence of serum sickness as, by the use of concentrated antitoxin, been educed to a fraction of what it was when uncon-entrated serum was used. An objection of another ind has also been raised. TH. MADSEN, R. KRAUS,[2] and others, have questioned whether the lassical Ehrlich method of titrating antitoxin units neasures the real value of an antitoxic serum, and uggest that two antitoxins of equal unit value may ary widely in therapeutic potency because one may ave a greater "avidity," and may therefore seize nore speedily and more firmly any toxin molecules t encounters. This problem is at present the subject f inquiry by a committee of the Medical Section of he League of Nations.

The methods of concentration hitherto described pply to antitoxins designed for use in the reatment of diphtheria, tetanus, scarlet fever, lysentery (Shiga), and diseases caused by the gas-gangrene bacilli. An entirely different method of oncentration consists in adding the specific antigen o an antiserum and obtaining an antigen-antibody omplex which is separated by the centrifuge and hen split into its two components. Thus, red blood-ells added to antiserum absorb the hæmolysin and hæmagglutinin, and may be then separated by edimentation or spinning. By warming in appro-riate alkaline or sugar solution the hæmolysin may e freed from the red cells and obtained in a solution ontaining a minimal amount of protein. HUNTOON n 1920 (Trans. Philadelphia Path. Soc., 1920, xxii., 75) added pneumococci to antiserum and thus inked the specific antibody to the cocci; he then entrifuged the preparation and, by treating the cocci n weak alkali, was able to detach a highly potent ntibody which contained but a minute amount of itrogen—so small that 5 c.cm. of the solution would ot sensitise a guinea-pig. This achievement was cclaimed in certain quarters as a proof that antibody was not necessarily protein in constitution, but bio-chemists to-day do not unreservedly accept this view. In the Ramon flocculation method, the toxin added to antitoxic serum forms a union with the specific ntitoxin. The floccules can be separated by spin-ning, a portion of the antitoxin detached from the oxin by warmth and acid, and a purified antitoxin obtained. At present this process is not apparently, we believe, economically applicable to the commercial production of antitoxin.

All proteins known may sensitise animals and produce some form of liability to anaphylactic phenomena; if, therefore, antitoxins could be prepared free of protein, presumably serum reactions and serum sickness would disappear. But unluckily this hope has not yet been realised. The promising pneumococcal antibody prepared by HUNTOON was not entirely free of the property of causing reactions. RAMON has stated [3] that his purified serum does not cause reactions; we cannot trace the publication of the details of the process of preparation and comment must therefore be reserved. It is of interest to note that the antibody to pneumonia prepared by FELTON,[4] which has also been successful in other hands (see THE LANCET, 1928, ii., 766), is obtained by a variation of these methods of concentration which are based on solubilities of the various protein fractions. New processes are likely to develop on similar lines. The keen interest of the academic biochemist in the real constitution of antitoxin, as well as the wholesome rivalry between members of the scientific staffs alike in State and in commercial serum institutes, leads to ever active attempts to improve the potency of the sera used by the practitioner in his daily work, while State control ensures their safety.

Annotations.

"Ne quid nimis."

THE KING'S HEALTH.

THE removal of the KING to Bognor marks a definite stage in his illness, but we protest again that it is premature to speak of convalescence. There has been throughout the past week a slow but definite increase in strength, and we learn that a slight improvement has even been observed in the weight. On two occasions the KING has been allowed to sit up for a brief period when the relief to monotony was beneficial, and was appreciated by the patient. The latest official bulletin calls attention to these facts while it refers to the further employment of ray therapy. The position here is that in the choice of rays and apparatus the clinical condition of the patient has throughout been the controlling anxiety. When treatment was begun the exposure could only be made for short periods and on portions of the body in order to reduce the degree of disturbance to a minimum. The need at that time was the stimulation of parathyroid activity, the adjustment of calcium metabolism, the rectification of the leucocyte count, and the raising of the bactericidal power of the blood. The mercury-vapour lamp was judged, at this serious stage of the illness, to be the method of choice in furthering these ends, and we understand that there is reason to think that the progress which occurred during the period of the application of rays from this source was in part due to their influence. Local treatment of the wound by ultra-violet light has never been employed. The improvement now attained renders possible treatment by the carbon arc, with its more penetrating luminous rays.

OBSERVATIONS ON CRETINISM.

IN the current issue of the *British Journal of Surgery* (1928–29, xvi., 370) Mr. R. Lawford Knaggs makes a further contribution to the study of bone disease by a paper on changes in the bones in cretinism. It is well known, of course, that one of the most striking symptoms of cretinism is a defect in growth, resulting in dwarfism, which is associated with underlying disturbances in bone development; the most readily recognised of these are delay in the appearance of the centres of ossification and delay in fusion of the epiphyses. No serious attempt has hitherto been made, however, to collect the contributions of different observers and correlate the clinical, pathological, and histological findings. Mr. Knaggs here discusses these matters both in relation to endemic and sporadic cretinism and to cachexia strumipriva. It appears that it is endochondral ossification which is deficient in all three types, though membranous bone formation also suffers in some degree. C. Wegelin [1] is of opinion that any difference in this respect between the three types is one of degree only, the defect being least in the endemic disease. There is, at any rate, a good deal of evidence to show that in the untreated sporadic cretin ossification is usually at a standstill, while the cartilaginous epiphyseal discs often persist throughout life. In the endemic form, on the other hand, ossification is as a rule no more than delayed and after 30 years of age the epiphyseal junctions and synchondroses are only exceptionally found open. Consequently there is a difference in the growth curves of these types, for whereas in the untreated sporadic case growth has stopped for the time being, in the endemic type, though growth is slow, it is seldom disturbed so completely. It is the condition of the long bones in the cretin which is of particular interest. Besides being much shorter than those of a normal person they are relatively shorter in proportion to the length of the trunk, though the disproportion is not so great as in achondroplasia. There are striking departures from the normal also in the skull of the cretin, especially in the sporadic variety. Its infantile character is shown by persistence of all the sutures and synchondroses, and the cartilage bones are imperfectly developed. The spine and pelvis show similar defects. Histologically, one of the chief features in the bones is a diminution in the amount of cartilage proliferation in the zones of ossification, but there are also changes in the bone-marrow, active cellular tissue being replaced by fat. The marrow changes result in a great diminution of the amount of active blood-forming tissue and are probably responsible for the anæmia so often associated with cretinism. Mr. Knaggs emphasises the importance of the marrow also in the process of ossification, for it invades the zone of preliminary calcification, absorbs the cartilage, and lays the foundation of the new medullary spaces. This invasion by the marrow is continually going on. When, however, the marrow is largely converted into fatty tissue its activity must be seriously interfered with and the growth in length of the long bones consequently more or less interrupted. It is this inefficiency of the marrow in the invasion and absorption of cartilage that some authorities, with Langhans,[2] regard as the primary factor in the disturbance of bone growth in cretinism. It would be interesting to know how far the bone defects can be made good by thyroid treatment. Judging by the satisfactory rate of growth which follows the administration of thyroid extract, especially in the sporadic cases, it seems probable that the underlying bone defects must be largely corrected, but further pathological evidence is needed before this can be definitely established. The satisfactory results of substitution therapy in the case of the sporadic cretin are well illustrated by a case reported by Dr. L. J. Witts on p. 284 of our present issue. The patient, whose mother was myxœdematous, was not treated for cretinism until she reached the age of 21 by which time the symptoms were well developed but considerable improvement followed the administration of thyroid extract. Subsequently she developed diabetes, which was controlled by dietetic measures and insulin, and under the continued administration of thyroid extract she later became pregnant. Unfortunately, owing to an oversight, during the later months of pregnancy she did not receive any insulin and developed diabetic coma. This was satisfactorily dealt with but shortly afterwards labour began spontaneously and she was delivered of a seven to eight months' fœtus, which showed early maceration. The patient herself remained in good health. This case is of great interest because pregnancy in a cretin is comparatively rare, and pregnancy in a cretin who has diabetes—a disease also inimical to pregnancy—is possibly unique.

PREVENTION OF DISEASE IN THE ARMY IN INDIA.

COLONIAL administrators will find encouragement in the story of preventive medicine in the British Army in India, as told by Lieut.-Col. J. Mackenzie in recent numbers [1] of the *Journal* of the Royal Army Medical Corps. A hundred years ago the death-rate only was considered, and that was 71 per 1000 men; mere sickness was thought inevitable, and was due mainly to cholera, dysentery, enteric fever, and malaria. In 1860 the death-rate had fallen to 32·5, but in 1867 it was carried up by cholera to 37. The provision of good water-supplies got rid of cholera, and probably lessened dysentery and enteric fever, though this last came into greater prominence in the eighties when young soldiers began to come out to India. In 1887 the death-rate was 15, and there was a notable fall in hospital admissions in 1898, in which year the first bacteriologist was appointed at Army Headquarters. In 1900 the admissions for malaria were 321·1 per 1000, and the Principal Medical Officer, Bengal, was considering if mosquito nets should be supplied. Ten years later they were being privately purchased by units; otherwise antimalarial work chiefly consisted of drainage and oiling. Since 1921, and especially since 1924, great efforts have been made, and the number of cases has decreased correspondingly. In 1925 an extra £7000 was allotted to antimalarial measures, and Major M. B. H. Ritchie drew attention in the Corps journal to the old idea of Hyder Ali, Sir Henry Lawrence (1846), Parkes (1864), and Sir Ranald Martin,[2] that European troops should be kept as much as possible in the hills. This idea, christened "cold storage," was accepted, and an educational malaria film was shown to all ranks and families. In 1926 £11,000 was allotted, and £20,000 for mosquito proofing of barracks. In 1927 "cold storage" was extended, propaganda was improved, and £14,000 granted for antimalarial measures. The cases treated fell from 472·3 per 1000 in 1924 to 297·3 in 1927. The methods of to-day are, to summarise Colonel Mackenzie's statements, keeping troops in the hills when they can be spared; mosquito-proofing of barracks; fumigation of hibernating mosquitoes; propaganda, especially the Rockefeller film; personal care; nets, fans, clothing; oiling and similar measures; effective treatment of cases; and cöordination under a malaria officer. The prevention of malaria was assigned as a duty to the R.A.M.C. in 1924, and the subsequent improvement has justified this decision and the heavy expenditure, for there were nearly 10,000 fewer cases in the British Army in India in 1927 than there would have been at the 1924 rate.

ETHER AND DUTY-FREE SPIRIT.

ALTHOUGH a few years ago there were some authorities who derided the advantages of pure ether, and indeed claimed for certain impurities the chief anæsthetic effects of the liquid themselves, to-day there is general agreement that this idea was unfounded. A large amount of good work, notably by J. H. Dale and H. King in this country and W. Storm van Leeuwen abroad, has established the fact that the purest ether is also the best anæsthetic ether. That being so, it is gratifying to know that at last it is possible for every manufacturer of ether to obtain rectified spirit duty-free for the manufacture of the anæsthetic. This desirable end has been brought about, we believe, largely through the activities of the Anæsthetics Committee set up by the Medical Research Council and the Anæsthetics Section of the Royal Society of Medicine. The result of allowing the manufacturers to get alcohol through the customs without duty should materially lessen the price of ethylic ether, and already we notice an announcement in our advertising pages showing that at least one firm has taken advantage of the opportunity to provide pure ethylic ether at the price hitherto charged for that from methylated spirit.

TYPES OF FOOT-AND-MOUTH VIRUS.

FOOT-AND-MOUTH disease has a double interest at the present time. Not only is it a constant menace to stock-breeders and the cause of serious economic loss, but it is one of the most prominent members of the group of virus diseases upon which so much attention is now concentrated. It is, in fact, the doyen of these maladies, since it was in connexion with it that Löffler and Frosch in 1908 first demonstrated the possibility of the transmission of a malady from subject to subject by body fluids deprived of visible cells or bacteria. In spite of the devotion of much time and energy to its study, very little of any moment has yet been discovered as to the nature of this disease or the method of its control. Most of the research, apart from the purely scientific question of its nature, has been concentrated on finding means to provide an effective artificial immunity to this acutely infectious disease. The problem has been the concern of many workers in different countries, and it has recently been re-stated from the French point of view by MM. H. Vallée and H. Carré[1] who, at the veterinary school of Alfort, have since 1920 continued the studies begun there in 1901 under the guidance of Roux and Nocard. The primary difficulty is to ascertain if the establishment of a true immunity is at all possible, since clinical facts and experimental investigations give very contradictory results. A factor in this confusion, perhaps the chief factor, has lately been disclosed in the discovery of the existence of different races or strains of foot-and-mouth virus which are immunologically distinct, though in other ways indistinguishable, and which do not confer any reciprocal immunity; in fact, the absence of such cross-immunity is the only criterion by which they can be distinguished from one another. The types of virus at present known are classified by Vallée and Carré as the O variety, obtained from the Department of the Oise, and the A variety, of German origin. The existence of these separate and immunologically independent strains explains many of the anomalous results previously obtained, including the occurrence of second attacks at short intervals after recovery from a first attack, and has enabled the duration of the immune period against a single strain of the virus to be effectively determined. Similar results have been obtained in other European countries and in the United States. As a result of many experiments, it seems that the immunity conferred against the O virus by an attack of the disease due to this type is of not less than a year's duration, although exceptionally second attacks and relapses occur. The O virus confers no immunity whatever against the A strain of virus, and this holds good in the opposite direction. The immunity developed against type A appears to be of somewhat shorter duration. It has been found possible to produce in the same animal a simultaneous infection with both types of virus, and as a result to procure a double immunity in the recovered animal. This procedure may point the way to the ultimate goal of a successful and lasting immunisation, although inasmuch as the active immunity which follows an attack is only of short duration, the prospect does not appear too promising. It may be noted that the results of certain efforts of Vallée and Carré to hyperimmunise animals artificially have had a directly opposite effect to that intended, and have resulted in the re-establishment of the receptive state. A third type of virus, known as type C, has recently been identified by O. Waldmann and K. Trautwein.[2] The problem of this specific virus disease is therefore one of many difficulties, not the least of which is that the investigator cannot apply ordinary bacteriological methods to its investigation.

EXPERIMENTAL ARTHRITIS DEFORMANS.

THE experimental pathology of chronic arthropathies has not so far led to much advance in our knowledge of the subject. Most of the work has had a bacteriological bias. Attempts to cultivate bacteria from the cavity and surrounding tissues of affected joints, and by inoculation to produce changes in the joints of animals, have not, however, yielded important results. Some observations made from an entirely different point of view give promise of yielding more fruitful results. R. Leriche and E. Brenckmann[3] found, in histological preparations of material removed from an affected joint, areas of necrosis of bone associated with areas of new cartilage and bone. They were led to formulate the hypothesis that necrotic areas of bone in the epiphysis actually provoked the laying down of new cartilage and bone. They proceeded to test this theory in animal experiments by inserting into a joint grafts of fresh bone taken from another part of the animal. Macroscopic and microscopic preparations at varying intervals after the graft had been implanted showed that a series of changes occurs with regularity. The graft quickly dies and is invaded by giant cells which slowly absorb it. About the fourth week, however, in the immediate neighbourhood of the graft, now in process of being absorbed, a rapidly growing mass of new fibrocartilage is found; this becomes penetrated by blood-vessels and later ossified. These new formations of bone and cartilage occur whether the graft is placed in the joint cavity or beneath the cartilage lining it. When the graft is fixed for 15 to 30 minutes in absolute alcohol before it is placed in the joint it is merely attacked by giant cells and absorbed; no new formation of cartilage or bone occurs. Leriche and Brenckmann have applied these results to the interpretation of the changes found in osteo-arthritis. If the phenomena occurring in these animal experiments take place also in pathological lesions of the joints in man, it seems possible that the formation of cartilage or osteocartilage in the articulations of man are consequent on necrosis in the bone or cartilage near the joint. If this is so, the source of the arthropathy is to be sought in the epiphysis, and the problem of the origin of these diseases will be reduced to finding the cause of foci of necrosis of bone and cartilage in the epiphyses. Dr. Leriche has long been interested in the normal and pathological growth of bone, and his experimental work on pathological lesions follows an exhaustive study of the problems of ossification in which with the collaboration of Dr. A. Policard, he has been engaged for more than ten years (see THE LANCET, 1928, ii., 662). His conclusions as to osteogenesis are heretical but command

[2] Berl. tierärztl. Woch., 1926, xlii., 569.
[3] La Presse Médicale, Nov. 14th, 1928, p. 1441.

respect since they are founded on very careful histological work. The investigation of the processes involved in the formation of new bone in osteo-arthritic joints may serve a double purpose in clearing up the physiology of bone growth, and will be followed with great interest.

COLONIAL VETERINARY SERVICES.

LAST July the Secretary of State for the Colonies appointed a committee to consider the best means of obtaining a high degree of efficiency in veterinary research and administration in the non-self-governing dependencies. The Colonial Office Conference had already approved the principle of the ultimate creation of a colonial scientific and research service. The report of the committee has just been published [1] and emphasises the profound importance for the health of the Empire of adequate veterinary activities. Meat- and milk-supply, the advance of agriculture, and the growth of fodder crops are all services that must depend upon the veterinary surgeon for their efficiency. His work can no longer be limited to the treatment of specific diseases or the prevention of the spread of epizoötics. Animal nutrition and genetics are of immense significance in the prevention of disease, and the collaboration of the veterinarian is essential in the solution of such problems as the trypanosomiases and virus diseases. The committee finds that the veterinary surgeon of to-day is involved in a vicious circle between the complaint that he is not scientific enough and the habit of treating him as inferior to his more scientific colleagues, so that men of high scientific training will not enter the profession. The veterinary departments of the colonies are on the whole understaffed and the standard of entrance to the service is low. There is no provision for post-graduate education; there is no research station, no system for collecting, editing, and distributing information, and no advisory authority on the larger aspects of veterinary work and research. The blame is distributed between the colonial Governments and the training and headquarters organisation of the veterinary officers. The former are responsible for inadequate interest, organisation, and financial support. The chief reform demanded of the latter is that the status and prestige of the service shall be considerably improved. The figures given in the report are sufficient to show the enormous importance of the veterinary problem, and the example of South Africa demonstrates the financial return to be obtained from expenditure on the veterinary service.

The first reform recommended starts at home, with improvements in the M.R.C.V.S. syllabus. Holders of the Natural Science Tripos or of science degrees are to be urged to enter the colonial veterinary service; students studying for the M.R.C.V.S. should be encouraged to take the B.V.Sc. or B.Sc. concurrently; and all newly appointed officers should have a special course of instruction in the peculiar problems of tropical veterinary science. A scholarship scheme is recognised as essential in order to build up the prestige of the service, although in the long run it ought to rely for recruits on its intrinsic attractions. The second line of advance is to be the provision of post-graduate courses in tropical veterinary science, including protozoology, entomology, helminthology, advanced pathology and biochemistry, animal nutrition and genetics, tropical hygiene and agriculture, and practical laboratory training. The committee recommends the establishment of a school of tropical veterinary science, modelled on the lines of the London School of Tropical Medicine, and gives detailed suggestions for its situation, curriculum, staffing, equipment, and finance. Thirdly, the report describes the advisory headquarters organisation that the committee would like to see established, to correspond with the advisory authority already existing on medical and legal matters, and with that shortly to be provided for agriculture. They suggest that an adviser on animal health to the Secretary of State for the Colonies and a consultative committee of animal health should be appointed, and that a joint body representative of agricultural and veterinary interests should be established. The duties of the official and these bodies are enumerated. Fourthly, the committee urges the organisation of research, finding that much valuable work is done under great difficulties and without possibilities of coördination. They consider that a new central research station should be established, preferably in East Africa, as a pivot for veterinary research in the colonial Empire; its staff is to consist as a minimum of a director, three senior and four junior research officers, a secretary-librarian, a recorder, a farm manager, an accountant storekeeper, an engineer, and four laboratory assistants. The report closes with a review of the colonial veterinary service as it is, and recommends the creation of a unified service including both specialists and field officers with salaries ranging from £600 to £3000 per annum. Officers are not to be limited to any particular colony, but their names are to be on a roster for service wherever required.

It will be obvious that the committee has executed its terms of reference thoroughly and painstakingly, and the report should be read with care by all who are interested in the wide problem involved. The reproach levelled at the present conditions of veterinary training should be taken to heart, not only by the authorities but also by the public, on whose goodwill—whether directly by donation or indirectly by taxation—improvement must depend. The report speaks in no measured terms of "lack of funds . . . apathy and lack of vision." The veterinary institutions visited caused "dismay at what we saw," and the contrast with those of other nations was "depressing." "Starved as they are of financial support, and cramped and confined in their activities, it is clear that impossible for the veterinary schools to give a training of the scope and quality needed. The profession must needs suffer in efficiency and prestige and consequently in the attraction it offers as a career to the youth of the country. A new policy is needed, framed on bold and comprehensive lines, supported by adequate funds, and carried through with energy and determination." The framing of the policy has been admirably done by this committee: it is to be earnestly hoped that the energy and determination will not prove lacking in those responsible for putting it into effect.

INSULIN AND THE DEATH-RATE FROM DIABETES.

THOSE who are acquainted with the remarkable results achieved by insulin in individual cases cannot help wondering that its introduction into general practice should have made so little impression on the diabetes death-rate. It is true that, like all innovations in medical practice, insulin has not been universally accepted, and that it will probably be many years yet before it is promptly and effectively employed whenever diabetes does not yield to dietetic measures. There remains the undoubted fact that very many doctors are using insulin and getting results from its use, while the death-rate from diabetes tends to rise rather than to diminish. Some light on the puzzling situation is thrown by a statistical analysis published in the December *Bulletin* of the Metropolitan Life Insurance Company of New York. When the death-rates are calculated for specific age-groups and by sexes, it is found that definite changes have taken place since 1922 when insulin was introduced. Among males the diabetes death-rate has declined steadily for all groups up to age 45. At ages 45–64 the rate has remained roughly as it was. For ages 65 and over there is a definite increase. Among females the decline is limited to childhood and early adult life. "After age 55," says the report, "the increase has been practically uncontrolled." This makes a great impression on the net death-rate, since in the company's experience nearly half of the total

leaths from diabetes occur in women over 50 years of age. The general conclusion from these observations, and from reports over the U.S.A., is that the incidence of diabetes, especially in women, is definitely on the increase. Insulin does not cure the disease, but does prolong life. Consequently the gain from death in early life is offset by a loss in later years. The economic prosperity of America tends to produce more diabetes and insulin may take credit that the rising death-rate is not rising more rapidly.

SILICOSIS AMONG SANDSTONE WORKERS.

"Masons' disease" is well known to sandstone workers, and many masons are so alive to the dangers of inhaling dust that they wet the stone on which they are working. Other workers exposed to stone dust in quarries and elsewhere are less conscious of risk, but the obvious possibility of their being subject to silicosis led the Home Office and Mines Department to coöperate in an inquiry, the result of which has just been published.[1] The investigation—conducted by two medical experts—was confined to workers manipulating sandstone who were in actual employment on building sites or in builders' yards and quarries in nine selected areas. Clinical examinations were made by both doctors of 454 men; 266 radiological examinations were carried out at the nearest centre possible, and 140 samples of atmospheric dust were taken for testing. Radiography revealed fibrosis, probably silicotic, in masons, stone-dressers, quarrymen, rock-getters, and planers, and severe clinical fibrosis was found amongst the older masons, stone-dressers, and quarrymen. The mason is a skilled workman who fashions stones by hand with chisel and mallet, sometimes in a confined space; his exposure to dust is continuous and severe. Quarrymen and stone-dressers work stone in a less detailed and skilled fashion than do masons; they use the pick and haul, but usually in the open air. Rock-getters work at the stone face in open quarries, using the hammer, wedge, crowbar, and drill; their exposure to dust is not intense and their work is intermittent. Fibrosis was found clinically among the older getters and planers, but most of them had previously worked in other capacities in the stone industry. Drillers who had been long at work showed fibrosis, but quarry labourers, cranemen, and sawyers seemed to be healthy. The progress of the disease was divided into three stages. In the first nodular shadows and an increase of hilum shadow, of linear shadows and pulmonary reticulum, were to be found radiographically; and there might or might not be some impairment of working capacity. In the second stage the X ray showed an increase in the area of nodular shadows with a tendency to confluence of the nodules; and there were clinical symptoms with some degree of incapacity for work. The third stage involved total incapacity. Of the 112 cases found 90 were in the first stage, 21 in the second, and 1 in the third. The greatest number of cases occurred between the ages of 45 and 54; the disease seemed to be more common after the fortieth year of age and the twentieth of employment in the stone industry. The symptom most often complained of was dyspnœa; some of the men had coughs and a few had had hæmoptysis. Quite half of them, however, had no complaints to make. Their statements about the most dangerous kind of stone were unreliable and conflicting; they seemed apt to confuse the idea of danger to health with the degree of difficulty in working the stone. It was, however, impossible to say that any kind of sandstone or gritstone is innocuous to workmen. As the inquiry was limited to men actually at work the incidence of tuberculosis, the onset of which rapidly incapacitates, could not be estimated. Clinical examination and X ray films suggested the presence of this disease in several cases; but in all the advanced ones the picture could have been produced by silicosis alone.

[1] Report on the Occurrence of Silicosis among Sandstone Workers. By Dr. C. L. Sutherland and Dr. S. Bryson. London: H.M. Stationery Office. 1929. 1s. 6d.

It was found possible to diagnose fibrosis of the lungs clinically at an earlier stage than the silicosis was shown radiologically. This recalls the similar finding in the pottery industry,[2] and stresses the importance of chest examination at regular intervals, especially of workers who have been employed for 20 or 30 years in close and continuous proximity to a fine dust-cloud produced by a steel tool from sandstone. Investigations into the dust-content of the atmosphere led to the conclusion that the action of wind in diluting and removing dust was most important. Unfortunately workers in sheds cannot always stand to windward of their own and their neighbour's work. Wetting the surface helps the "getter," but does not greatly affect the fine dust produced by a cutting tool. To be effective water must be applied directly and in considerable quantity. Steam effectually lays dust produced in drilling. Respirators were used in some districts, but were very inefficient, and the men would not always wear them.

This report gives some measure of the occupational risk to which masons are exposed, especially when they are working a closely grained sandstone with its quartz particles closely packed and cemented by secondary silica. The investigators found 112 out of the 454 men they examined affected more or less—i.e., about one in every four. South African experience teaches that for early simple silicosis after a period of ten years there will be about the same number surviving as if the original diagnosis had been simple tuberculosis. If, then, we envisage the stone-mason, spending an otherwise fairly healthy life in the open air, having one in four afflicted with tuberculosis, we get some grasp of what this dust disease—silicosis—means in fatality. The only point in its favour is that it does not generally occur until middle life. Against this risk there is little to-day which can protect the man; steam, water-spray, and exhaust draughts for removing dust are not economically practical in the stone industry. A device is receiving attention whereby the dust may be removed when pneumatic tools are being used. But the simpler method is to give up using sandstone wherever possible. Already artificial wheels are replacing grindstones in the cutlery industry; there is no reason why the modern tendency to build with reinforced concrete should not be extended, while limestones have given to London its most beautiful structures, and Hampton Court stands as an instance of what can be done with bricks. Compensation has just been awarded for silicosis occurring in the stone industry; possibly this economic influence will go far to abolish the use of sandstone, which, we may say, is far less used in other countries than it is here. Medically we cannot but hope that the sandstone industry will be "improved" in this country out of existence.

[2] Report on the Incidence of Silicosis in the Pottery Industry. H.M. Stationery Office. 1926. 1s. 6d.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Feb. 11th Mr. Andrew Wylie will lecture on "The Difficulties Experienced in the Diagnosis of Laryngeal Diseases" at 5 P.M. at 11, Chandos-street, London, W., where, on Feb. 14th, at 4.30 P.M., Dr. Gerald Slot will lecture on Calcium Therapy. On Feb. 11th also Mr. Aubrey Goodwin will give a clinical demonstration in gynæcology at 2.30 P.M. at the Prince of Wales's General Hospital, Tottenham, and on Feb. 12th, at 6 P.M., Dr. J. E. M. Wigley will hold a clinical demonstration at St. John's Hospital, Leicester-square. On Feb. 13th, at 4 P.M., Dr. Daukes will give a demonstration on Various Types of Ulceration in the Intestinal Canal at the Wellcome Museum of Medical Science, 33, Gordon-street, W.C. On Feb. 11th a two weeks' course in gynæcology will begin at the Chelsea Hospital for Women and a four weeks' course in diseases of the skin at St. John's Hospital, Leicester-square. An intensive course will be held at the Brompton Hospital from Feb. 25th to March 2nd, and from Feb. 25th to March 9th a comprehensive morning course at the Hospital for Sick Children, Great Ormond-street. An eight weeks' course is in progress at the National Hospital, Queen-square. Further information may be obtained from the Fellowship of Medicine, 1, Wimpole-street, W.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XXI.—THE SIGNIFICANCE OF OCULAR TESTS.

II.—Binocular Tests.*

When one eye fixes an object the other does so too; the slightly dissimilar images which are formed on the two retinas are interpreted as a single one. This power of seeing with both eyes simultaneously is called binocular vision, and that of fusion of the two images into one the fusion faculty. In some persons binocular vision is absent or poorly developed, in which case the vision in one eye is suppressed while the other is in use.

Test for Binocular Vision.

The presence or absence of binocular vision may be ascertained by placing a red glass transmitting only red rays before one eye, and a green glass transmitting only green before the other, the patient being told to look at a test object consisting of two strips of glass, red and green, illuminated by a light behind them. If binocular vision be present both red and green will be seen, but if absent either the red or the green, according to which eye is in use, and which suppressed.

The *stereoscope* also is employed as a test for binocular vision and the fusion faculty, two dissimilar pictures being used—for example, a bird on one side and a cage on the other. A normal person will see the pictures superimposed, the bird appearing to be in the cage, but if binocular vision be absent one or other picture only (either the bird or the cage) will be seen.

The Amblyoscope.—There is evidence that in some cases of concomitant squint a certain degree of binocular vision may be present, but that suppression of one eye may take place. The amblyoscope is an instrument which has been devised for the purpose of ascertaining the presence or absence of binocular vision in squint cases.

It consists of two metal tubes joined at one extremity by a hinge, so that the angle at which they are set can be altered at will to suit the angle of the squint; by this means it can be so arranged that each eye looks straight down its corresponding tube. At the ends of the tubes dissimilar pictures, translucent, so that they can be illuminated by extraneous light, are placed—e.g., bird and cage—and the power to perceive the pictures simultaneously proves the presence of binocular vision. This instrument is also used in cases of concomitant squint to train and develop the fusion faculty, which, if present, is usually feeble and may be improved during childhood by stereoscopic exercises.

Diplopia Tests in Ocular Palsies.

When normal binocular vision is present it is necessary, in order to obtain single vision, that the image of each object directly looked at should fall upon the central fixation point, or macula, of each eye; otherwise diplopia would occur. The external ocular muscles which move the eyes are so coördinated as to secure single vision in all positions of the eyes. In cases of *paralysis* or weakness of one or more muscles of one eye this coördination is lost, and binocular diplopia (double vision) results. If they are completely paralysed the affected muscle or muscles can easily be detected by making the patient move his eyes in all directions, when actual limitation of movement of the affected eye in the direction of the paralysed muscle can be seen. But where only muscular *weakness* is present, it is often impossible to detect any abnormality in the ocular movements by direct observation, and in such cases the diplopia experienced by the patient is used subjectively to determine which eye, and which muscle, or muscles, are affected.

The patient puts on a spectacle frame in which are mounted a red and a green glass, the former in front of the right eye and the latter in front of the left. The observer stands before the patient at a distance of about one metre holding a light, which is moved in all directions in turn, the patient being told to follow it with his gaze. When the eyes are moved towards the weak muscle coördination is lost, and the image of the light seen by the patient separates into two, a red and a green, the former belonging to the right eye, and the latter to the left; this separation of the images increases the further the light is moved in that direction.

By observing the position or positions in which diplopia occurs, and the relative position of the true and false images, the affected eye and affected muscle can be determined.

Paresis of an ocular muscle points to an organic lesion affecting either muscle or nerve, and is never a hysterical condition. It is present in many diseases of the nervous system, as well as in other conditions, and if a patient complains of diplopia the elucidation of the cause of this symptom is always of great importance. Ocular paresis, though not the only cause of diplopia, is much the commonest one.

Test for Heterophoria.

The external ocular muscles are normally perfectly balanced in a state of tone, so that there is an equal pull in each direction. This normal condition, in which the eyes remain straight without effort, is known as *orthophoria*. The muscular pull may, however, be of unequal strength; for instance, the internal muscles may be stronger than the external, the external stronger than the internal, or again there may be an upward pull on one eye against a downward pull on the other. When binocular vision is absent or suppressed, so that only one eye is used at a time, there is no stimulus for the eyes to remain straight; they then take up a position of rest, and the lack of balance becomes manifest as a concomitant squint, convergent, divergent, or vertical. In the presence of normal binocular vision, on the contrary, the eyes do not squint, but are kept straight by an unconscious effort: this effort is instinctively made in order to avoid the extremely uncomfortable diplopia which would result if the eyes were allowed to squint.

This condition of latent squint is termed *heterophoria*, and it is of great importance to be able to detect its presence and to measure its amount, since the unconscious effort to keep the eyes straight may give rise to distressing subjective symptoms, such as headache, giddiness, and nausea, with perhaps occasional diplopia. These symptoms may be relieved by the wearing of suitable prisms, or in extreme cases it may even be necessary to operate on the ocular muscles in order to attain a beneficial result. In other cases, again, treatment by means of exercises may be undertaken.

A rough test for the presence of heterophoria may be made by screening one eye with a card or the hand, while the other is made to fix a finger of the other hand. The eye covered by the screen moves away into the position of rest, and if the screen be removed quickly can be seen to move back at once into the position of fixation.

Maddox Rod.—Measurement of the amount of heterophoria is commonly carried out by the use of a Maddox rod. This consists of several rods of red glass, set side by side in a circular frame which is placed in front of one eye in an ordinary pair of spectacle testing frames. If a spot of light is looked at through this system of rods it becomes a streak of light.

The patient looks at a small spot of light six metres away, and while the uncovered eye sees the spot of light as a spot, the other eye sees a red streak, into which the light is transformed by the glass cylinders. This streak differs so much in appearance from the light that the eye does not interpret it as being the same object; for this reason there is no stimulus to keep the eyes together, and the eye behind the rod takes up the position of rest, just as it would if behind an opaque screen. If no heterophoria be present the covered eye remains straight and the streak is seen to cross the light, but if the balance of the muscles is abnormal, and the covered eye has moved out of the straight position, the streak will not fall on the centre of that covered eye, and will therefore appear to be at some distance from the light.

* Part I., Monocular Tests, appeared in THE LANCET last week.

For the purpose of testing the lateral muscles the d is placed so that the streak is vertical, while for sting the elevator and depressor muscles it is rotated to a horizontal position. The amount of deviation the vertical streak to one side or other of the light, in the horizontal position above or below the light, ay be measured by the strength of prism which, hen placed in front of one eye, is required to make ie streak appear to coincide with the light—the otical effect of a prism is to alter the apparent position objects looked at through it, so that they are splaced towards its apex. Or the deviation of the reak from the light may be measured on a scale arked in tangents, the light at which the patient is oking being in the centre of the scale. The patient is ked to say with which division of the scale the streak pears to coincide, its distance from the light giving e tangent of the angle of deviation.

Accommodation of the eyes for near vision, volving as it does the act of convergence, affects the alance of the external ocular muscles, and for this ason separate tests should be made both at six etres and at normal reading distance.

For the purpose of testing muscle balance at the tter distance special instruments have been devised r the sake of convenience, but their underlying inciple is the same—viz., that of dissociating the ages seen by one and the other eye, and thereby olishing the stimulus to keep them straight.

Test for Congenital Colour-blindness.

This condition is of importance in that it is a bar to rtain occupations, especially the railway and marine rvices. Many tests have been devised for its detec-on, one of the best known being the "*Holmgren's ools*" test. This consists in asking the candidate to lect from a heap of coloured skeins those which match colour certain specially chosen "confusion colour" mple skeins. Another test in common use is *dridge Green's lantern*, into the illuminated aperture which various coloured glasses can be placed in rn, under variable conditions of lighting, the ndidate being asked to recognise these colours. ther tests consist of a series of cards on which certain atterns made up of specially arranged multicoloured scs are printed, the recognition of these patterns pending on a normal colour sense.

Estimation of Intra-ocular Tension.

The *tonometer* has been devised as an adjunct to the timation of intra-ocular tension by means of the gers, and the type of instrument most commonly ed is the tonometer of Schiötz. Its circular concave otplate, designed to fit the cornea, is held lightly on ie previously cocainised eye, the patient being in a cumbent position, and the tension of the eye is dicated by a pointer which moves along a graduated ale.

The tonometer is by no means an instrument of athematical accuracy, and is relative rather than bsolute in its readings. While it can never replace ie tactile sense for the estimation of intra-ocular nsion, it is of real value when used by experienced ysicians in certain cases of glaucoma.

R. AFFLECK GREEVES, F.R.C.S. Eng.,
Surgeon to Moorfields Eye Hospital, Ophthalmic Surgeon to the Middlesex Hospital.

PAYING PATIENTS AT MANCHESTER.—At the annual eeting of the Manchester Royal Eye Hospital it was stated at the beds reserved for paying patients, a system begun year ago, are "an unqualified success, and have filled a ed which has been long felt." Nearly 33,000 out-patients ere treated, and accident cases numbered 11,848, an erage of 32 per day. Next year the Grangethorpe Ortho-edic Hospital will be vacated by the British Red Cross ciety, which has held it since the war, and will come into ssession of the Manchester Royal Infirmary. It is suggested at it should then be used as a hospital for the middle-asses. The number of beds in the Manchester hospitals served for paying patients is very small, notwithstanding ie large demand. Grangethorpe is in a quiet pleasantly tuated spot, within easy access of the infirmary.

Special Articles.

RADIUM TREATMENT OF CANCER IN FRANCE AND BELGIUM.

A VISIT TO THE CLINICS OF PARIS AND BRUSSELS.

BY DONALD J. ARMOUR, C.M.G., M.B., F.R.C.S.,
SENIOR SURGEON, WEST LONDON HOSPITAL;
AND
HENRY S. SOUTTAR, C.B.E., D.M., M.CH., F.R.C.S.,
SURGEON, LONDON HOSPITAL.

THE treatment of cancer by radium is receiving a degree of attention rarely accorded to any therapeutic method, and it is only natural that, at the many centres at which it is being practised, technical methods should have developed in different directions. It is therefore imperative that those who wish to be familiar with the latest advances should visit the different clinics at which radium treatment is being carried out, as only in this way is it possible to gauge the value of the results which have been obtained, or to form any idea of the lines along which progress is likely to proceed. With this object we have spent some time at the centres of radium therapy in Paris and Brussels, and we feel that it may be of value to others if we now report briefly the results of our observations. In the very short time at our disposal it was obviously only possible to take in general principles and to form very broad ideas. We have, however, returned home stimulated by the brilliant work we have seen, profoundly impressed by the solid progress which is being made, and not a little touched by the warm reception with which we have met and the generous way in which every avenue has been opened to us.

Paris.

Our first visit was to the Institut du Radium (26, rue d'Ulm, Paris Ve), which practically forms the out-patient department of the Fondation Curie. Under the directorship of Prof. Regaud the Institute has made great strides and is generally recognised as holding the leading place in the world. Prof. Regaud devotes the whole of his time to the work of the Institute and of its clinical section in the rue Antoine-Chantin. He is supported by Dr. Monod and Dr. Roux-Berger, familiar names in surgery, and by a large staff of highly trained assistants. The Institute works in association with the University of Paris, but, unlike most of the Continental clinics, it is a private society and does not depend directly upon the Government. It possesses seven grammes of radium, large X ray installations of the very latest types, clinical and experimental laboratories, and every facility for the convenient and sympathetic handling of patients; it has fully equipped laboratories for animal research, and adjoining it are the physical laboratories of the Institut Curie itself. On the afternoon of our visit "consultations" were in progress under the charge of Dr. Monod, assisted by Dr. Tailhefer, and it was an interesting example of French practice that the junior surgeon carried on the consultation, whilst the senior, Dr. Monod, sat beside and only occasionally gave a word of advice.

First there came a long series of cases of carcinoma of the cervix, and here for the first time we got an impression of the extraordinary prevalence of this condition in France. Most of the cases were of long standing and had been under treatment for years, and it was easy for us to follow, from the elaborate notes which were produced, the progress of each case and to see the various forms of treatment which had been adopted. There followed a series of cases of cancer in

other regions, chiefly the breast and face. Of these perhaps the most remarkable were a series of cases of epithelioma and of rodent ulcer of the face, some still untreated, many completely cured, and a few showing small recurrences after treatment.

The consultations finished, we were shown over the whole of the Institute by Dr. Marjorie Greene of the Royal Free Hospital, who is working as an assistant at the Institute, and whose knowledge both of the Institute and of our mother tongue was a delightful surprise. We were greatly impressed by the plain efficiency of all that we saw and by the elaborate care with which the notes of every case are preserved. In every single case the removal of a fragment of any tumour for microscopic examination is the unbroken rule, and no case is admitted to the statistics of cancer in which this proof is lacking. In most instances photographic records are preserved and in every case details of treatment and of progress are recorded in the most precise manner.

Approximately half the space of the Institute is given up to an elaborate X ray installation, to which we know of no rival in this country. The advantage of being able to combine radium treatment with the very latest methods of X ray therapy is too obvious to require comment, and it is not to be wondered at that in the hands of a clinician so experienced as Prof. Regaud such striking results have been obtained. We were surprised, however, to find that little attention is paid to radium emanation, only 300 mg. of radium being devoted to its production. The contrast with the opposite tendency in English practice was striking, and this was still more the case when we found that no emanation at all was used at the other centres which we visited.

Only next in interest to the Institute of Radium itself is the Centre Anticancéreux at Villejuif (14, Avenue des Écoles), one of the southern suburbs of Paris. Over this, the chief Government centre for the suburbs of Paris, presides Prof. Roussy, professor of pathological anatomy in the University of Paris, assisted by Dr. Bertillon, Dr. Wickham, and Dr. Mme. Laborde. Commencing as a small outgrowth from a poor-law hospital this has now become the "Institut de Cancère de la Faculté de Médecine de Paris," and it will shortly be accommodated in modern buildings covering a large area, including a hospital built on the most modern lines and laboratories which will be unrivalled for their purpose.

We were met by Dr. Bertillon, who spent more than three hours in showing us the hospital as it at present exists, and all the complicated apparatus which has been evolved for radium treatment. Dr. Wickham was engaged in consultations and we had the opportunity of being present at these and of seeing the actual application of some of the methods which we shall describe later on. We shall also refer later to the organisation of which Villejuif is an important centre, and which Dr. Bertillon explained to us in some detail. For the moment we will only mention two incomparable pieces of apparatus. One was a "radium bomb," a great mass of lead weighing half a ton, so delicately poised that it could be moved in any direction with a touch, and containing 1 gramme of radium. It was very securely locked. The other was an X ray installation operating in absolute silence at a pressure of 200,000 volts. Somehow we began to have doubts about the blighting influence of Government control.

Brussels.

Brussels is unique in that it holds practically the whole of the radium supply of the world. The deposits of Haut Katanga on the Belgian Congo were only discovered in 1922, but they soon eclipsed in production all other sources of radium. From them the Radium Belge Company draws its supplies for the works at Oolen, where extraction and purification are carried out. In the form of the bromide, radium is sent to the laboratories at Brussels, where for the most part it is converted into insoluble sulphate and packed into the needles and other containers in which it finally reaches the market. There is no question at all of any shortage of the element, which can be supplied at once by the Radium Belge in almost any quantity. We ourselves saw no less than 10 grammes in the Company's safe at Brussels. Owing to the kindness of the assistant director, Monsieur Adam, we were allowed to see the laboratories and to watch the methods by which the radium is handled, and we were greatly impressed by the scientific accuracy with which every process is carried out, and by the care with which every step is controlled.

At the Institut du Radium (7, rue Wéry) we were received by Dr. Sluys, the director, and by Drs. Neuman, Coryn, and Cahen, surgeons on the staff of the Institute. Here again we were impressed by the elaborate care with which records are kept and statistics prepared, and we were not a little envious of the organisation which made this possible. From the clinical point of view we had come on a bad morning, but we saw two cases of carcinoma of the rectum which had been operated upon by Dr. Neuman, after treatment with radium. In both cases he had been able to remove what was previously an inoperable tumour and in both the result was brilliantly successful. The methods of treatment adopted in the Institute were fully explained to us and we saw many of the appliances in use. Dr. Sluys, who has transferred his skill as an artillery officer to the service of radium, is concentrating upon treatment from a distance, and he showed us a most elaborate apparatus by means of which radiations from 13 "cannons," each containing a large source of radium, can be focused with the greatest accuracy upon one centre. By a mechanism of extraordinary ingenuity this centre can be shifted with precision so as to occupy any position within the body of the patient, with the net result that an enormous dose of gamma rays can be concentrated at a series of points, although the rays themselves pass through entirely different areas of the surface of the body, and the skin is saved from what would otherwise be a destructive dose. For a description of the apparatus we must refer to Dr. Sluys's papers, but for originality in conception, ingenuity in execution, and precision of action, it could not be excelled.

Methods of Treatment.

It is evident both in France and Belgium that the line along which most progress is expected, and on which most work is being done, is in the use of gamma rays from a distance. Radium is regarded chiefly as a convenient source of these rays of short-wave length, and it is used for their production very much as if it were a special form of X ray tube. The most striking example of this was the radium bomb which we saw at Villejuif, containing one gramme of radium and destined exclusively for the production of gamma radiations. But this was only one example of the general trend of thought.

The same principle was exemplified in the many ingenious appliances which we saw for supporting tubes of radium at a fixed distance from the surface of the body. In France these appliances were for the most part made of Columbia wax, a mixture of paraffin, beeswax, and sawdust, which can be moulded easily into any form. In the case of malignant deposits in the glands of the neck, for example, a thick collar is made of wax carefully moulded to the patient's neck and shoulders, and from 1 to 3 cm in thickness. On the outer surface of this the needles of radium are embedded, the needles themselves being platinum tubes with walls at least 0·3 mm. in thickness. The face is protected by a lead screen embedded in the wax cast. As a result the small percentage of beta rays which escape through the platinum is absorbed by the wax, as are also the secondary beta radiations which arise from the platinum itself. The net result is that the patient receives a pure gamma radiation, carefully distributed so that no portion of the skin receives a dangerous dose, whilst the glands beneath are subjected to a converging cross-fire.

In Brussels the same result was obtained in a somewhat different way. A thin case was made, exactly moulded to the contours of the body, and constructed of shavings of lime-wood glued together. On this light foundation were supported blocks of cork or of light wood so that each tube of radium was supported accurately at a distance of 5 cm. from the surface of the body. The tubes themselves were placed at approximately the same distance from one another, the whole area being so mapped out as to provide a uniform radiation to the surface, whilst again the principle of the converging cross-fire was maintained. The advantage of this system over wax was the extreme lightness of the appliance and the better ventilation provided.

The technique of needle insertion did not differ much from that practised in this country, except that it appeared to be usual to employ larger doses than are customary here. Needles containing 10 to 15 mg. of radium were not uncommon, beta rays being cut off by a platinum wall, 0·5 mm. or more in thickness. On the whole, however, the insertion of needles was not regarded with great favour, and our suggestion that operable cases of carcinoma of the breast might be treated in this way was evidently regarded as a dangerous heresy. In Brussels, however, we were told that good results had been obtained by the insertion of radium needles into the broad ligaments after a laparotomy in certain cases of cancer of the uterus, whilst we have already referred to two cases of cancer of the rectum removed after radium treatment by Dr. Neuman.

We were very much struck by the number of cases of cancer of the cervix which we saw, and the number must indeed have equalled that of all the other cases of cancer with which we met. The treatment appeared to be standardised and consisted in the insertion of a lead tube containing a large dose of radium into the cervical canal, whilst smaller amounts were packed into the lateral fornices. These were left in for five or six days and the patient was then subjected to heavy doses of deep X rays as a routine. The results appeared to be excellent, for many of the cases we saw were cured cases of long standing.

What we have said applies to general surgery, but in dermatology extensive use is being made of the direct application of radium, so that the beta rays have full effect. In Paris Dr. Paul Degrais, of the Hôpital Necker, showed us wonderful examples of the results which he has obtained in lupus, keloid scars, and angioma with surface applications of radium on varnished plaques. Most remarkable of all were several cases of huge cavernous angiomas in the face and neck in children, in which the local external application of radium had produced the most brilliant cures. From the method of application it is evident that the effect must be largely one of scarring from the action of the beta rays, although in the cases of keloid growths this will hardly explain the remarkable results which he has obtained. For rodent ulcers and epitheliomas, on the other hand, he has used large amounts of radium in heavy platinum or thick silver needles, with results maintained after several years.

Government Organisation.

The immense interest taken by the French Government in the problem of cancer is very obvious. By the kindness of M. Henri, director of the Radium Belge in Paris (54, Avenue Marceau) we were introduced to M. Géry, head of the special department of the Ministry of Health (offices, 7, rue Cambacères), devoted to this object and coördinating under its central control a series of 15 centres distributed throughout France. Each of these centres is to some extent autonomous and organises the work in its own district. Of the centres outside Paris the most important is Villejuif, which takes charge of the whole of the suburbs of Paris, and we owe to Dr. Bertillon a description of its work. At each centre is concentrated a large supply of radium and a staff who are expert in its use, whilst the patients are drawn from a series of sub-centres at which consultations are held on definite days of the week. Doctors in the surrounding districts send their cases into these sub-centres, and often accompany them in order that they may get the opinion of the expert. In this way patients are saved from useless journeys, and the central hospital from unsuitable patients, whilst the public, recognising the advantage of such a convenient arrangement, seek advice at a much earlier stage than would otherwise be the case. The clinics at the sub-centres are advertised widely by means of posters in which the word "cancer" is freely used, and stress is laid on the immense advantages of early diagnosis and treatment. We were very greatly impressed by the masterly skill shown in the organisation and the simple effectiveness of every detail. Some idea of the extent of this organisation may be gained from the adjoining table, and those who are familiar with French surgery will recognise many distinguished names among the directors of the centres. The amount of radium element available at each centre is a fair measure of its importance, and the grand total certainly furnishes food for reflection. It must be remembered that this does not include private supplies, and we were informed that the total amount of radium in France available for the treatment of cancer exceeds 50 grammes.

Regional Centres in Campaign against Cancer.

Conclusion.

Although it must be very obvious from what we have said that France has seized radium with both hands, and that she is far ahead of us in organisation, we would not have it thought that we do not fully appreciate the splendid work which is being done in England. Our personal debt to the Radium Institute of London, to Mr. Hayward Pinch and his staff, and to our many friends in other centres, is far too great for that to be possible. Our visit has indeed convinced us that in many ways we are in advance of our Continental colleagues, and we have returned with an increased admiration for the work of our own countrymen. But we went to France and to Belgium to learn, and we have learnt a great deal about the surgical possibilities of radium. We have learnt still more of the warm hearts of our colleagues abroad, who placed their time and their resources so generously at our disposal, and we feel that we can best show our appreciation by urging our colleagues on this side to follow our example.

MEDICINE AND THE LAW.

Problems of Consolidated Legislation.

THERE are puzzles in the mechanics of law-making as well as in the substance of the law. The Food and Drugs (Adulteration) Act, 1928, consolidating and replacing the previous enactments, did not come into force till Jan. 1st, 1929. The licensee of a Wimbledon hotel was summoned last week on the charge of having sold whisky to which 9 per cent. of water had been added. The alleged offence took place in December, the charge was heard at the end of January; under which Act should the proceedings be taken? The prosecution chose the new Act, whereupon counsel for the defence objected; the 28 days within which the summons could be taken out having elapsed, it was now too late to initiate proceedings under the old Act. The magistrates ruled that the objection was valid, though Section 37 of the 1928 Act provides that samples taken under the old Act are available under the new. This latter point may be important if a case is stated for the opinion of a higher court. A year or two ago, it may be recalled, proceedings against a defendant under the Dangerous Drugs Acts were terminated abruptly in the Court of Appeal because the prosecution had relied upon the Act of 1925 and that Act was not yet then in operation.

Another misunderstanding over the consolidation of enactments occurred in the House of Commons on Jan. 30th. Regulations under the National Health Insurance Act must be laid before Parliament and may be attacked by the presentation of an address to His Majesty (by either House) within 21 days; if such an address is presented, the Regulations must be annulled. The National Health Insurance (Medical Benefit) Consolidated Regulations have come into force but were liable to attack in this fashion for the 21-day period. They consist mostly of clauses which were already part of the law, but they also embody a few new features. Mr. W. Hirst, M.P., moved an address praying for the annulment of the Regulations, but it appeared that his objection was to the old law, not to the new. He was reopening hostilities towards a provision dating back to last April under which it is forbidden to give inducements, discounts, or rebates in connexion with panel prescriptions. The coöperative societies resent this prohibition because it prevents the writing of dividends on prescriptions presented by members to the societies' drug departments. On the other side the retail chemists argue that to distribute dividends on prescriptions is to given an indirect incentive to malingering; the patient, they say, has an interest in increased prescriptions and this involves extra work for the medical practitioners; moreover, to distribute profits to coöperative society members may suggest to the Minister that the margin of profit at present allowed on health insurance prescriptions is too high and ought to be cut down. The merits of this dispute were not fully debated in the House of Commons on the recent motion, for the Speaker ruled the motion out of order. The power to pray for annulment of Regulations applies only to new Regulations laid before Parliament, not to old Regulations which are being reproduced by consolidation. The Minister pointed out that the motion could not have the desired result. If the recently laid Regulations repeal and replace Regulations made last April to the same effect, their annulment would merely revive and restore the identically similar Regulations of last April.

An Inquest without a Body.

The wisdom of our ancestors established the legal principle that there could be no coroner's inquest of death unless there were a dead body lying within the area of the coroner's jurisdiction. It might be difficult to say whether scanty remains of a human being amounted to a dead body within the Coroners Act, but coroners were often content to hold inquests upon almost any recognisable portion of a human body and occasionally, when once the inquest was opened, evidence of other portions became available. In R. *v.* Haslewood in 1926 the High Court reaffirmed the old rule that there could be no inquest unless the coroner viewed the body; if the coroner omitted this duty the proceedings were extra-judicial and void. The amending Act of 1926 permitted an inquest to be held, upon the special direction of the Secretary of State, where death is believed to have occurred within the coroner's jurisdiction and where "owing to the destruction of the body by fire or otherwise, or to the fact that the body is lying in a place from which it cannot be recovered," an inquest would not otherwise be held. Where such an inquest is held without a body, the law relating to coroners and inquests is to apply subject to any necessary modifications. The Home Secretary gave a direction under this new statutory power with regard to the supposed death of an electrical engineer named Jenkins who was believed to have travelled in the train which met with an accident at Charfield last October. No trace of his body was found. His landlady, who lived at Derby where he worked, said he left her house to catch that train to visit his mother at Milverton in Somerset. A solicitor's clerk who travelled on the train identified Jenkins from a photograph as a man who had joined the train at Derby and had said he was going to see his mother in Somerset; he left the man in a compartment alone at Birmingham. A railway official verified the issue of a week-end ticket from Derby to Taunton (near Milverton) at the proper date. Only two other pieces of evidence were before the coroner's court. One was a shoe found among the debris of the accident some weeks after the smash. It was originally brown and had turned black; his landlady gave the rather vague testimony that it looked something like the brown shoes which Jenkins used to wear. The other was the fact that there were still two bodies taken from the scene of the accident and still unidentified. Dr. Welchman Ward, of Wootten-under-Edge, said neither of these could have been Jenkins; one was obviously the body of a child, the other was that of a youth 13 or 14 years old. The jury found that Jenkins had been on the train and had been accidentally killed.

It will be noted that the inquest was not upon the unidentified bodies which had presumably been dealt with at the earlier inquiry into the death of the victims of the accident. It was, in effect, merely an inquiry whether Jenkins was alive or dead, the sort of issue which might affect a life insurance policy or would determine the question of death registration. The proceedings thus became analogous to the more expensive course of applying to the Probate Division for leave to presume the death of a person who has disappeared, when affidavits of belief of death are required. It is possible that stronger evidence of death would be necessary for one purpose than another. Supposing, for instance, the engine-driver had been criminally negligent and all the other passengers except Jenkins had nevertheless survived the accident, would the disappearance of Jenkins have amounted to proof of death sufficient to support a charge of manslaughter?

REMOVAL OF QUEEN CHARLOTTE'S HOSPITAL.—The managing committee of Queen Charlotte's Maternity Hospital has decided to remove the hospital, with the nurses' home, the post-graduate and students' college, from the Marylebone-road to a quieter site. Plans have been prepared, the approval obtained of the Ministry of Health and King Edward's Fund, and negotiations for the acquisition of a new site are proceeding. It is proposed that the buildings should comprise an isolation block for cases of puerperal fever, with space for research laboratories, with the object of attacking the problem of maternal mortality. This will be the first block to be erected. Another block is to be devoted mainly to prenatal cases. Rooms, on a comparatively extensive scale, are to be provided for paying patients of moderate means.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Influenza in Dublin.

ALTHOUGH the medical officer of health for Dublin has thought it necessary to advise the closing of the schools for the period of a fortnight, the type of influenza in Dublin at present appears to be mild. Some cases of influenzal pneumonia are coming under treatment, but are by no means severe. Nevertheless, the disease appears to be affecting the mortality tables. In the week ending Jan. 26th the mortality in the Dublin Registration area was 23·6 per 1000 per annum, while for the four weeks ending on the same day the rate was 19·9, a rate equal to the mean for the corresponding period of the previous ten years. The deaths, 192 in number in the current week, included 6 assigned to influenza and 14 from pneumonia.

The Rotunda in Need.

The governors of the Rotunda Hospital have issued a special appeal for the sum of £20,000, which is urgently needed to carry out the improvements which are necessary to keep the hospital in the front rank of modern progress. It is many years since there was any capital expenditure on the hospital. A new operating theatre is required. The pathological laboratory is too small, and there is insufficient accommodation for the X Ray Department and for the Infant Care and Prenatal Care Departments. The main part of the present building has been in use for over 170 years, since it was built by Bartholomew Mosse, the founder and first Master of the hospital. The Rotunda was the first maternity hospital in the British Empire, and until recently was the largest. It still retains its position as the premier obstetric school, and its many contributions to the science and art of midwifery are well known. At present the hospital attends over 4000 confinements in the year. It is to be hoped that the governors will receive a generous response to their appeal, so that the hospital, under the progressive guidance of its present Master, Dr. Bethel Solomons, may continue to hold its high place.

An Unqualified Practitioner Sent to Prison.

Last week, in Dublin, Rasfara Mahare was convicted by a jury of posing as a qualified medical man without being registered, and was sentenced to two years' imprisonment—the maximum penalty for the offence—and fined the sum of money found in his possession. An advertisement in the papers had drawn the attention of the police, who acted with such promptitude that the man was only a fortnight in Dublin before he was arrested. He said that he had been practising in England for 20 years. Subsequent to his conviction the State Prosecutor stated that the police had reason to believe that the prisoner had been attempting to start the white slave traffic in Dublin. He had been known under 16 different aliases, and had been previously convicted 23 times. The prompt action of the police was commended by the judge.

British Pharmaceutical Conference.

It has been announced that the forthcoming meeting of the British Pharmaceutical Conference is to be held in Dublin this year, and will open in the Mansion House on June 24th. Invitations have been issued to 300 pharmaceutical associations in Great Britain. Arrangements are being made for attractive amusements for the visitors as well as for the work of the Congress. It is 27 years since the Conference last met in Dublin.

The Work of the Local Appointments Commission.

At its last meeting the Council of the Irish Medical Association expressed its approval of the method of making appointments under the Local Authorities (Employés) Act. This approval, in which all intelligent and honest opinion agrees, does not purport to cover all the methods adopted by the Local Appointments Commission. Some of the grievances to which candidates are subjected were discussed at a meeting of the Munster Branch of the British Medical Association held in Cork a few days earlier. It appears that a candidate for an appointment has to pay a fee of £1 to £2, and has also to pay his own travelling expenses for an interview with the Selection Board. Some of these fees are returned to unsuccessful candidates. A candidate who applies later for another appointment has to undergo the whole process and expense again. One gentleman declared that within the past year applications for positions cost him £50. This heavy taxing of candidates is all the more inexplicable in that the professional members of the Selection Board are in the habit of giving their services gratuitously. It appears to be unnecessary and irritating to summon all candidates, and not only those on a select list, to an interview. The present method is a great advance on the previous method of making appointments, but it should only be regarded as a step to the establishment of a State service with entrance by competitive examination.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

*Local Government (Scotland) Bill.**

MEDICALLY the new Government clauses for treatment of sick persons are by far the most important in the whole Bill. They deserve the most careful study. In essence they are really a reversion to the general power to provide "hospitals for the sick" contained in the Public Health (Scotland) Act, 1867. But, under that Act, nothing whatever was done to provide for anything but infectious diseases. In the 1897 Public Health Act provision by local authorities was restricted to infectious diseases. Now the wider conception is again established. The clauses cover at one sweep the whole problem of the treatment of sickness. It is enough to say that these comprehensive clauses, which affect the voluntary hospitals as well as the official hospitals, have the support of all those familiar with Scottish hospital problems. Any scheme to be approved under the new Act by the Department of Health must provide that all reasonable steps are taken to secure full coöperation with every voluntary hospital, university, or medical school within the area or serving it.

Aberdeen Hospital Scheme.

The new Royal Hospital for Sick Children at Aberdeen has now been formally opened by Viscountess Cowdray. This hospital, it is important to remember, is an entirely independent body. The funds for it have been collected over a period of 18 years. The war interrupted the project for a new hospital; but, fortunately, a site was available on the same campus as will ultimately contain the buildings of the "Joint Hospital Scheme." Architecturally the hospital adds to the reputation of Dr. William Kelly, A.R.S.A., whose work for the last 40 years is conspicuous among the Aberdeen public buildings. Meanwhile the fund of £400,000 for the new Royal Infirmary on the same campus is within £30,000 of completion. This is a marvellous record. It shows two things: first, that Prof. Matthew Hay's conception was on sound lines, and second, that a very widespread community is now conscious of the need for an institution with full modern equipment in association with a great teaching medical school. The Woodend Hospital, opened in 1927, will be supplemented by the more adequate new Royal

* The opening discussion on the Bill in Committee in the House of Commons is reported in our Parliamentary columns.—ED. L.

Infirmary, and Aberdeen will thus become a typical example of regional grouping of hospital institutions around a medical school. This idea is rapidly gaining ground in Scotland.

Influenza.

For the week ending Jan. 19th the notifications of acute primary pneumonia and acute influenzal pneumonia in Scotland numbered 748 and 303 respectively. This was for large burghs and populous areas only. In Glasgow alone the numbers were 554 and 220. For the week ending Jan. 26th, the corresponding figures were: pneumonia, 1175; influenzal pneumonia, 504; for Glasgow alone, 813 and 332. Notifications thus show the same relative increase as the deaths. In Glasgow for the four separate weeks ending Jan. 26th, the deaths from influenza were 14, 49, 149, and 233; for pneumonia, 59, 118, 187, and 297; for bronchitis, 39, 70, 108, and 107. Totals, 116, 253, 342, and 654. These figures indicate an epidemic expansion. The notifications are, of course, not a complete indication of the amount of influenza, as a recent visit to Glasgow convinces me. Medical men themselves have been very largely affected; but the attacks have been mild and the urgency of practice makes sufficient personal care impossible. The extreme fatigue following exertion is a very usual phenomenon. In Edinburgh influenza is also prevalent, but the exact figures are less readily available. Prevalence is, however, indicated by the fact that several public functions have been postponed and absenteeism at schools has been marked. At one public dinner, 22 apologies for absence were received. However, the weather conditions of Edinburgh, though fairly severe, have not been as detrimental as in the west.

Housing in 1928.

The full official figures for 1928 are now available. The table issued by the Department of Health presents many interesting national features as against the corresponding figures for England.

	Completed.	Under Construction.
1919 Act	25,129	—
do. (by Public Utility Societies) ..	421	—
Private Subsidy Schemes (1919) Additional Powers Act	2,324	—
Slum Clearance Schemes	8,668	2,683
1923 Act—by Local Authorities ..	4,006	—
do. —by private enterprise ..	14,502	2,378
do. —by Public Utility Societies	80	—
1924 Act—by Local Authorities ..	29,668	10,165
do. —by private enterprise ..	549	795
do. —by Public Utility Societies	77	50
Demonstration Houses	17	—
Steel houses erected on behalf of Government by Scottish National Housing Company	2,552	—
	88,013	16,071

Under the Addison scheme 25,129 houses were completed by local authorities. Houses by public utility societies numbered a trifling 421, and by private persons subsidised, 2324. Meanwhile the slum clearance schemes, entirely a local authority affair, have accounted for 8668 completions and 2683 under construction. The 1923 Act—that is, the Chamberlain Act—produced only 4006 by local authorities, but a large number by private enterprise—namely, 14,502 completed and 2378 under construction. Undoubtedly the Chamberlain Act gave a great impulse to private building. But the greatest impulse to local authorities has come from the 1924 Act—that is, the Wheatley Act—under which the local authorities have produced 29,668 houses, with 10,165 under construction. Under the same Act, private enterprise produced only 549, with 795 under construction. This is a great contrast to the working of the Chamberlain Act and the Wheatley Act in England. Taking all the Acts together, and including both the houses completed and under construction in 1928, Scotland has now 104,084. Knowing the enormous difficulties that confronted all building projects in Scotland when the Royal Commission reported in 1917, I can only regard this as marvellous progress; the pace will be steadily maintained until another 100,000 houses shall have been provided. Particular areas may be affected slightly by the phenomenal distress in the mining and iron trades; but probably this is a cause that operates adversely in England as well. It is worth remembering that the housing movement was initiated by representations from the mining areas of Lanarkshire in 1909. This led to several preliminary inquiries and surveys. The Royal Commission was not issued until 1912, and, owing to war delays, did not report until 1917. The first legislation on the report came in 1919. The Scottish Commission had stimulated England, and Dr. Addison, then Minister of Reconstruction, adopted at once the principal Scottish recommendations.

Public Health Services.

WHOOPING-COUGH.

To those in touch with the epidemic prevalence of whooping-cough it will come as no surprise to learn that since the beginning of the year there has been a definite rise in the incidence of the disease, the London County Council returns for the week ending Jan. 12th indicating that 1000 children were absent from the schools under their jurisdiction from this cause alone. That number may be compared with the similar weekly return of Dec. 8th, 1928, when 400 school-children were reported to be suffering from whooping-cough. Corroboration of the increased attack-rate will be found in the fact that on Jan. 30th of this year, in the Metropolitan Asylums Board hospitals for acute cases of infectious disease, there were 712 whooping-cough patients, or approximately 17 per cent. of the total numbers in these hospitals on that day. From these figures by themselves it is impossible to obtain more than a general idea of the true proportions of the epidemic, but it may be of interest to recall that only once has the above number been exceeded in the Board's hospitals since they were opened for the reception of whooping-cough in 1910—viz., on March 15th, 1927—when the cases of this disease under treatment numbered 789. The disease seems never to have completely disappeared during the summer months of 1928, and, as indicated by the hospital returns, there was an appreciable increase during the autumn months which, in turn, has been followed by a sharper rise in the admission rates since the beginning of this year. It is to be supposed that if the epidemic wave is following its usual course in London we are still 8–12 weeks removed from the period of maximum epidemicity, and it seems likely that a yet greater demand will be made on the resources of the hospitals. Should this coincide with an appeal for the removal of any large number of cases of influenzal pneumonia, the distribution of the available accommodation in accordance with the necessities of the situation will require considerable thought.

So far as can be observed at present whooping-cough is not showing any abnormal degree of severity in London, and this is reflected in the returns of the Registrar-General for the weeks ending Jan. 19th and 26th, in which we find 16 and 28 whooping-cough deaths respectively. It is interesting to speculate as to how far this improved figure is due to hospitalisation, a procedure which has now become current in public health work. Statistical evidence in support of this policy is very hard to come by, and is certainly not to be found even by the most intensive study of records of infectious hospitals by themselves, but no one with practical experience of this class of work can doubt that children from overcrowded, insanitary homes, during a period of stress such as that brought

bout by an attack of whooping-cough, have their hances of survival enormously increased by removal o a hygienic environment. At present, so far as reatment is concerned, this is the most that can be rovided for them, no specific remedy being available. Drugs without number have been recommended, ut few would be so bold as to claim consistent uccess with any. Recently ultra-violet radiation as been extolled, but the results await confirmation, nd preliminary work in this country has shown that his agent must be employed with caution lest dormant hest complications be stirred up. Abundant fresh ir and careful attention to the patients' nourishment re still the principal points in the treatment, whilst roncho-pneumonia must be dealt with on general ines. For the past few years workers whose interests ie on the bacteriological and clinical sides of the nfectious diseases common to this country have irected their attention mainly to the elucidation f problems opened up by the recent discoveries n diphtheria, scarlet fever, and measles. On the cientific side little that is new has appeared on the ubject of whooping-cough, and a fresh reconsideration f the whole problem from the bacteriological and mmunological standpoints is urgently called for.

INFLUENZA.

CLINICAL reports received from districts throughout England and Wales during the past week indicate that there is still considerable prevalence of influenza in Manchester, Oldham, Salford, Altrincham, Warrington, Wigan, Liverpool, and North-west Cheshire. Yorkshire and the rest of the North of England appear fairly free, as do the Midlands, with the exception of Derbyshire, Leicestershire, Newport (Salop), Hereford, and Coventry. It is reported from Bristol that fewer cases are occurring and the rest of the South and West of England shows no marked epidemic. The incidence in London appears to be rather sharply localised, Kilburn and Harlesden reporting large numbers of mild cases and Surbiton some incidence, while nothing noteworthy is reported elsewhere. A fair amount of the disease is occurring in Surrey and Berks. It is increasing in Cardiff, and epidemics are reported from Cwm Bran, Neath, Flint, and Denbigh.

In Glasgow the deaths reported during the week ending Feb. 2nd were 184 (a reduction of 52 on the previous week) and in Belfast there was a marked rise in the influenza mortality, the deaths numbering 105 as against 78 and 9 in the previous weeks. It was reported from the United States on Feb. 1st that influenza is decreasing in all parts. During the week ending Jan. 26th 55,000 cases were reported. The reports published by the Health Section of the League of Nations indicate no noteworthy change in the European situation. In Germany the returns for the Ortskrankenkasse indicate that the incidence is lower in Berlin, Breslau, and Leipzig, but increasing in Bremen. In Berlin the case mortality among the members was 3·3 per 1000, as compared with 2·4 in January, 1927. The only countries from which fresh reports of epidemic influenza have been received are Esthonia and Czecho-Slovakia; in both the type of the disease is mild.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 26TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 239; scarlet fever, 2582; diphtheria, 1427; enteric fever, 26; pneumonia, 2422; puerperal fever, 31; puerperal pyrexia, 113; cerebro-spinal fever, 5; acute poliomyelitis, 3; acute polio-encephalitis, 1; encephalitis lethargica, 22; dysentery, 16; ophthalmia neonatorum, 94. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 20 counties: London, 13 (of these St. Pancras 5, Wandsworth 4); Chester, 3 (Ellesmere Port and Whitby); Derby, 37 (of these Bolsover 23); Durham, 51; Essex, 11 (West Ham); Huntingdon, 1 (Norman Cross R.D.); Lancaster, 4; Leicester, 8 (County Borough); Lincoln, parts of Kesteven 5 (Stamford); Middlesex, 1 (Heston and Isleworth); Northampton, 7 (County Borough); Northumberland, 19 (of these Tynemouth, 18); Nottingham, 6 (of these Worksop (R.D., 5); Soke of Peterborough, 6; Stafford, 9 (of these Stoke-on-Trent 8); Suffolk, East, 1 (Stowmarket); Surrey, 2 (Mitcham, Wimbledon); Yorks West Riding, 33 (of these Castleford 14); Glamorgan, 10; Monmouth, 12.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Jan 29th–30th was as follows: Small-pox (46 under treatment, 1 under observation); scarlet fever, 1904; diphtheria, 2095; enteric fever, 14; measles, 54; whooping-cough, 712; puerperal fever, 26 (plus 11 babies); encephalitis lethargica, 77; poliomyelitis, 4; "other diseases," 50. At St. Margaret's Hospital there were 13 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 58 (0) from measles, 10 (0) from scarlet fever, 104 (28) from whooping-cough, 58 (15) from diphtheria, 40 (7) from diarrhœa and enteritis under two years, and 321 (77) from influenza. The figures in parentheses are those for London itself.

The number of deaths from influenza during the previous eight weeks was 56, 60, 61, 69, 83, 99, 122, and 179 respectively, the rate of rise being steeper in the last two weeks. The figures for London during the previous eight weeks have been as follows: 11, 10, 9, 9, 15, 18, 34, and 39 respectively. The deaths from influenza in the week under review again occurred largely in the Midland and Northern counties: Liverpool, 43; Manchester, 23; Portsmouth, 13; Warrington, 10; West Ham, Southampton, Sheffield each 8; Birkenhead, 7; Birmingham, Wallasey, Bolton each 6. Glasgow reported 236, and Belfast 78 during the same week. The two deaths from enteric fever outside London occurred at Bolton and Barrow-in-Furness. Liverpool reported 12 deaths from measles, Cardiff 7, Birmingham 6, and Gateshead 5. Whooping-cough deaths are much more evenly distributed over the country: Liverpool reported 8, Manchester 7, Leeds 5, Birkenhead, Warrington, Bolton, and Hull each 4. Manchester reported 4 deaths from diphtheria, Liverpool 6 deaths from diarrhœa.

The number of stillbirths registered during the week was 286 (corresponding to a rate of 43 per 1000 births), including 48 in London.

Death from Small-pox.—The fatal case provisionally classified to small-pox in the returns for the week ended Jan. 12th was that of a male patient, aged 65 years, who was admitted on Jan. 7th to the Small-pox Hospital at Halifax, where he died the following day. He was suffering from lobar pneumonia (left lung) and small-pox, and Dr. Wilfrid Smith, acting medical officer of health, writes that he considers the immediate cause of death was pneumonia. Small-pox was inserted on the death certificate as an additional cause.

BIOLOGICAL DIAGNOSIS OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—The occasional great difficulty and importance of making the diagnosis of early pregnancy are so well recognised that any diagnostic test, that is said to be reliable, calls for serious consideration and examination. The latest such test, the Zondek-Aschheim test, promises to prove itself reliable, for the results of those who have tried it extensively indicate only a 2 per cent. incidence of error. This test, which was recently described in your columns,[1] depends on the presence of a hormone in the urine of the pregnant woman, which the original observers believe to come from the anterior lobe of the pituitary body; and any theoretical doubts, which may exist in the minds of some as to the identity of the hormone, do not affect the validity of the test. The urine is injected into immature mice, and the result depends upon changes which occur in the ovaries of the animals in the course of a few days, and which are recognisable by an expert both macroscopically and microscopically.

The only practical difficulty in the adoption of the test is the need of a suitable supply of test animals under the care of an expert. This difficulty has been overcome in Edinburgh by my colleague, Prof. F. A. E. Crew, of the Genetics and Animal Breeding Research Department, and in Mr. B. P. Wiesner, Ph.D. Vienna, a member of the staff, we have a distinguished expert with the available material. May I therefore inform the profession through your columns that in order both to test thoroughly the reliability of the Zondek-Aschheim reaction, and at the same time to be of help if possible in different cases, Prof. Crew and Dr. Wiesner are prepared and willing to employ the facilities of the department in regard to any specimen sent to it. The test is said to be valid from 14 days after the first missed menstrual period. All that is required is to send a few ounces of the patient's urine, with a covering letter containing the clinical and other data, to the Animal Breeding Research Department, King's Buildings, University of Edinburgh. It is proposed to charge a modest fee of 5*s.* in each private case, to cover the cost of the animals and other material, and this fee will enable similar tests to be made for the reduced fee of 1*s.* 6*d.* in all hospital cases referred to the department. The result of the test will be notified by post to the sender about a week after the urine is received.

The help which the test has already afforded to me in several cases in the last three months leads me to believe that in throwing their facilities open to the profession in this country Prof. Crew and Dr. Wiesner are offering us very great practical assistance, and I hope that many of my colleagues will take advantage of these arrangements.

I am, Sir, yours faithfully,

R. W. JOHNSTONE.

University New Buildings, Edinburgh, Jan. 31st, 1929.

ASTHMA RESEARCH.

To the Editor of THE LANCET.

SIR,—My letter was not an advocacy of any method of treatment—I know too little for that—but quite definitely a plea for the serious consideration of the psychological aspect of asthma in any scheme of research. I now quite accept the fact that Mr. Coke, as a biochemical expert, does not believe that psychopathology has anything to offer towards the understanding of the problem of asthma.

His defence of the "stigma" upon the neurotic, the nervous, or the neuropath (I use his terminology in humble ignorance of the clinical or pathological differences it implies) has a frankness that makes clear the danger of moral judgments as scientific or diagnostic criteria. Let me repeat his argument, substituting "asthmatic" for the words of opprobrium: "If the number of asthmatics in the world were doubled, the health of society at large and the peace of the individual at home would be very adversely affected; if it were halved, the nation would be far happier. Therefore, the asthmatic is not an element for good, and in so far as he fails to add his quota to the general happiness of the world, so far is he a nuisance, and so far do his asthmatic manifestations carry a stigma." There seems no flaw in the argument, thus presented, that does not equally apply to the original.

Mr. Coke should study "Erewhon," where he will find described a country where emotional disturbances, though classed with delinquency, were openly treated as disease, whilst physical disorders were concealed as disgraceful; measles meant imprisonment, toothache was despicable, and asthma might have led to permanent detention. This bitter sarcasm of the neurotic Samuel Butler, whose books still give pleasure to many readers, prompts the wish that he were alive to answer Mr. Coke with an argumentum ad hominem. The shade of Dr. Johnson, a sufferer from neurotic, nervous, or neuropathic obsessions and inhibitions, might find words suitable to the occasion; or we might invoke the literary aid of Thomas Carlyle, who with his sound-proof chamber was as much a nuisance as any physical invalid. The gentle Elia, with his neurotic stammer, would be too diffident for the task, but Lord Roberts might in military fashion defend the thesis that a cat phobia is as respectable as a cat asthma and equally a concern of medicine.

But the shades of these eminent neurotics might shrink before the moral disapproval of Mr. Coke and even, as many neurotics in the flesh certainly do, keep their symptoms to themselves when they scent it. He tells us that he is not totally ignorant of psychotherapy, and speaks of useful conclusions arrived at by sympathetic questions. May we try to imagine a psychopathologist "stirring up the deeper pools of memory with a long stick and grabbing the dead leaves as they come to the surface" together with a companion picture of Mr. Coke sympathetically questioning a neurotic whom he is about to stigmatise?

"When the patient said that cats gave him asthma he was disbelieved; now, by means of the skin reactions, full justification of his statement is possible." Who disbelieved him? What is Mr. Coke's attitude to the man who says that cats make him physically ill with terror? Is this sufferer to be disbelieved, despised, and stigmatised because his reaction takes a shape for which Mr. Coke cannot find a biochemical formula? Or shall we as scientific men seek whether we can learn anything from the study of these curiously related conditions?

I am, Sir, yours faithfully,

MILLAIS CULPIN.

Queen Anne-street, W., Feb. 3rd, 1929.

To the Editor of THE LANCET.

SIR,—One is inclined to agree with Mr. Frank Coke that his views on psychology are not likely to be interesting, not at the present stage of his education; but it is otherwise with his ideas about the "science of psychotherapy" of which he claims that he is not ignorant. As a practical man I for one should like to hear more of this scientific psychotherapy which is apparently founded on disbelieving the patient. "Neurotic tendencies," he says, "were wrongly imputed to the asthmatic in the past by a profession which was totally ignorant of the main causes of asthma as now recognised. When the patient

[1] THE LANCET, 1928, ii., 834.

said that cats gave him asthma, he was disbelieved." The old Adam in myself often makes me want to doubt the patient, but I should humbly suggest to Mr. Coke that the beginning of psychological knowledge is founded on believing that what the patient says is true.

Mr. Coke with his bright optimism has much contempt for the unhappy neurotic, and he gives his reasons. Here, perhaps, a book on logic will help him more than one on psychology. Every word he says of the neurotic is equally applicable to the sufferer from any illness whatsoever. I venture to parody his words with the one substitution of the word "sick" for the word "neurotic" or "nervous." Thus: "If the number of sick in the world were doubled, the health of society at large and the peace of the individual at home would be very adversely affected; if it were halved, the nation would be far happier." No one will dispute so obvious a proposition. Let us therefore add his conclusion. "Therefore, the sick man is not an element for good, and in so far as he fails to add his quota to the general happiness of the world, so far is he is a nuisance, and so far do his sick manifestations carry a stigma."

Is it a book on logic, however, or a little common charity that is wanted?

I am, Sir, yours faithfully,

T. A. Ross.

The Cassel Hospital for Functional Nervous Disorders, Penshurst, Kent, Feb. 2nd, 1929.

VACCINATION AGAINST SMALL-POX.

To the Editor of THE LANCET.

SIR,—In your account last week (p. 231 et seq) of the recent discussion on vaccination against small-pox, I am made to say in the course of my reply that we have not got an efficient vaccine virus. What I did say was that we had not got an efficient *killed* vaccine virus and that, while further research towards the securing of a modified virus capable of yielding protection against small-pox was eminently desirable, experimental investigations hitherto conducted had given small grounds for optimism.

I am, Sir, yours faithfully,

J. C. G. LEDINGHAM.

Lister Institute, London, Feb. 4th, 1929.

To the Editor of THE LANCET.

SIR,—Referring to the discussion of the Section of Epidemiology of the Royal Society of Medicine (reported in your columns last week), I venture to doubt whether "alastrim" has been proved to be such a stable variant of small-pox as some of the speakers supposed. According to Dr. Rajchman, it made its appearance in England in 1919; but the late Dr. J. C. McVail pointed out in the Milroy Lectures for that year that two sorts of small-pox had been prevalent in England since about 1902, a severe form in London, and a milder form in the provinces. The fatality of the mild form was 6 or 7 per cent., of the severe, from 12 to 25. A very notable fall in the provincial fatality occurred in 1921, when it was only 1·4 per cent. Since that year it has dropped still lower. Is the present-day mild small-pox (alastrim) a direct descendant of Dr. McVail's mild, provincial form, or is it a later imported variant? And if alastrim is a stable variant, was Dr. McVail's mild form also a stable variant? I observe that Dr. Monckton Copeman stated that the alastrim he saw in 1903 in and about Cambridge was of a more severe type than in most of the recent outbreaks. It appears, therefore, that during the past 28 years there have been present in this country at one time or another two, if not three, varieties of mild small-pox, besides the classical, more or less severe, form.

It is interesting to note that a similar question of identity of disease has arisen during recent years in the cases of typhus and scarlet fever. Prof. Ledingham said that "he thought that sufficient consideration had not been given to the possibility that the virulent form of small-pox had been somewhere incident alongside the alastrim, but without definite transitions." I quite agree with his opinion. So far as I am aware the two forms have not, in this country, been prevalent together at the same time in the same place. It would be a crucial test for those who believe alastrim to be quite a different disease from small-pox, to place cases of each disease together in the same ward of a hospital to observe whether patients suffering from the one became infected by the other. It is stated in the *Monthly Epidemiological Reports* (Feb. 15th, 1928) issued by the League of Nations that "small-pox of severe type appeared in June, 1927, in Northern Rhodesia, where ordinarily only the mild Kaffir-pox is met with. During the first 20 weeks of 1927 140 cases with only 4 deaths were reported, giving a case mortality-rate of 2·9 per cent.; between the twenty-first and the fiftieth week of that year there were 856 cases and 170 deaths, giving a case mortality-rate of about 20 per cent."

The questions arise, was Kaffir-pox (amaas) replaced by severe small-pox or did the former change into the latter, or did the two run side by side? Perhaps the report of this discussion will be the means of eliciting information on this point. According to the latest returns small-pox has become less frequent and less severe again in Northern Rhodesia. With this history before us we should not assume that the present mild form in England may not at any time become more severe or be replaced by a more dangerous form.

I am, Sir, yours faithfully,

E. W. GOODALL.

Hemingford Abbots, Hunts, Feb. 4th, 1929.

MYOFIBROSITIS.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Neave's inquiry as to the evidence which supports the view that fibrositis is really the cause of the symptoms which are usually attributed to it, the following points may be mentioned. In 1904 when Sir William Gowers[1] in a lecture on "Lumbago: its Lessons and Analogues" first suggested the use of the word "fibrositis" for the malady, he regarded it as an inflammatory lesion of the fibrous tissue but admitted that "at present we are without any direct evidence of the real nature of these affections, such as can only be furnished by microscopes and modern methods of discerning that which it reveals." This evidence was supplied soon afterwards by Prof. R. Stockman[2] who stated that "the lesion consists in inflammatory hyperplasia of the connective tissue in patches." He and Dr. C. J. Renton demonstrated that microscopic examination of nodules excised during life showed a "localised inflammation of the perimysium," in short, a fibrositis. The microphotographs which illustrate his paper show clearly this condition.

I am, Sir, yours faithfully,

Manchester, Jan. 29th, 1929. GEORGE R. MURRAY.

SUBMUCOUS RESECTION OF THE NASAL SEPTUM.

To the Editor of THE LANCET.

SIR,—I am much interested in your annotation last week (p. 244) on this operation, the most valuable in rhinology. So much sense and so much nonsense have been written concerning it that one finds extremists stating that they "have never seen any good come of the operation" and others who cannot admit failure. Recently I wrote[3] upon the Essentials

[1] Brit. Med. Jour., 1904, i., 117.
[2] Edin. Med. Jour., 1904, xv., 108.
[3] Practitioner, September, 1928.

of Septum Operations and, as I have performed over a thousand of these operations, I may claim to be entitled to an opinion and to be permitted to recapitulate briefly what I consider to be these essentials. The factors which count for success are good illumination, a skilled anæsthetist accustomed to coöperate with the operator, careful preparation of the nose, thorough operation, and an after-treatment entailing as little interference as possible. I may add that I prefer general anæsthesia as affording more freedom in operating. I have also long been accustomed to operate in the sitting or, occasionally, in the semi-recumbent position.

The greatest care of the muco-perichondrio-periosteal flap is essential, together with thorough separation and isolation of the bony cartilaginous septum. For the palatal crest I have long discarded chisel and gouge in favour of Huff's cutting forceps, which are neater, clean-cutting, and more easily controlled. Failure is often due to not removing enough of the septum, but due regard to the preservation of an anterior buttress to support the nasal bridge must be taken. Enlarged posterior ends of inferior turbinates should always be removed when present; failure to do so seriously militates against effective operation. Plugging for 24 hours is another essential, and compressed gauze, cut into suitable splints, well coated with sterilised vaseline, and carrying anterior loops of flat "French braid" for their easy removal, is best for this purpose. The absorption of moisture swells these splints and ensures effective pressure on the new septum, making sutures unnecessary. I have never seen a "flapping septum" in my cases since I used them. As regards after-treatment, nasal washes, forcible blowing through the nose to clear the passages, and other meddlesome methods are provocative of complications and disaster, and it is foolish to permit the patient to leave the nursing home before a week has elapsed.

I am strongly of opinion that if these essentials be adhered to bad results will be reduced to a minimum. At this stage of my experience I can say that such bad results as I have encountered occurred in my early days of operation. The procedure calls for experience and technique of a high order, and not even the best of us can avoid occasional failure. We can, however, take no risks, and when failure occurs in spite of every care, it will be found to lie in the non-recognition of some general condition of the patient.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Wimpole-street, W., Feb. 4th, 1929.

"INDUCED" COUGH IN DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—Among the many instructive precepts emerging from Dr. S. Vere Pearson's address on Pitfalls in the Diagnosis of Pulmonary Tuberculosis in THE LANCET, Jan. 12th, and from the correspondence following it, I see no reference to the value of the "induced" cough. In many cases in which the sputum provided by the patient has proved negative, an "induced" cough has provided a positive one and has enabled the physician to embark confidently on the appropriate course of treatment. There are various methods by which a useful cough can be "induced," which I have so recently set out in your correspondence columns,[1] under the heading "Obtaining a Specimen of Sputum," that I need not repeat them here. Possibly such methods are frequently employed, but they have not received the attention I think they deserve, and I offer them as a small contribution towards the avoidance of pitfalls in the diagnosis of early tuberculosis of the lungs, as I have found them in early tuberculosis of the larynx.

I am, Sir, yours faithfully,

London, Jan. 28th, 1929. JAMES DUNDAS-GRANT.

[1] THE LANCET, 1928, ii., 679.

THE TREATMENT OF HÆMORRHOIDS BY INJECTION.

To the Editor of THE LANCET.

SIR,—Mr. Morley accuses me of misquoting. I therefore give the exact text of the official report which followed the proctological meeting at the Royal Society of Medicine on July 9th, 1924—i.e., the paragraph relating to the general opinion expressed on the submucous injection treatment of hæmorrhoids:—

"The general opinion, after a full discussion, was that in selected uncomplicated cases definite improvement could be promised, and in some cases permanent cure was effected, but the likelihood of recurrence in perhaps 50 per cent. of the cases indicated the necessity for periodical re-examination and further injection as required."

I fail to see in what way I misrepresented the gist of the matter in the words I used in my letter to you.

Mr. Morley does himself an injustice. I read very carefully his book on Hæmorrhoids (1923) and I find on p. 54:—

"However, my objections to all these solutions are more or less theoretical, because my results with the 20 per cent. solution of carbolic in glycerine and water have been so uniformly satisfactory that I have resisted temptation to experiment with any others, &c."

Why, then, if Mr. Morley's results were then so uniformly satisfactory do we now find him using the very weak preparation of 5 per cent. phenol in almond oil? The curious point is that on the same page (54) of his book Mr. Morley writes: "I should not feel very confident of injecting an oily solution, because, etc." But Mr. Morley in this book also expresses the opinion that a 10 per cent. solution of phenol is too weak (also p. 54); so that one feels bewildered at the various changes in Mr. Morley's opinions.

In his letter last week criticising my subsidiary article on the Treatment of Hæmorrhoids by the Galvano-cautery (*British Medical Journal*, Dec. 8th, 1928), Mr. Morley uses the words "alarming list of complications." Yet my paragraph on complications starts with the words "These, fortunately, are very rare"—and I leave to your readers to decide whether or not this is fair comment. When my statistics are published Mr. Morley may be surprised. From memory I should say that the cures, after three years and upwards, will work out at something like 99 per cent., including all cases without any selection.

I am, Sir, yours faithfully,

W. S. WHITCOMBE.

Harley-steeet, W., Feb. 4th, 1929.

ABERGELE SANATORIUM.—As a result of representations put before the Ministry of Health by a deputation from the Finance Committee of the Manchester Corporation, it now seems probable that the Manchester Corporation will get the full grant (about £14,000) towards the cost of the sanatorium erected by the corporation at Abergele. The town clerk has received a letter from the Ministry of Health stating that the Minister is disposed to think that he would be justified in proposing that such special provision should be made.

MEDICAL REUNION IN PARIS.—A medical reunion will be held in Paris from June 9th to 14th; it will be organised with the coöperation of the *Revue Médicale Française* and its contributors, and will be open to medical men and students from all countries. The constitution of the Central Committee is as follows: President, Prof. Delbet; Vice-Presidents, Prof. Sergent and Prof. Desgrez; general organiser, Prof. Balthazard; general secretary, Dr. Léon Tixier; assistant general secretary, Mr. Deval; treasurer, Dr. Léon Giroux. The meetings will be held in the Palais des Expositions, Paris (Porte de Vaugirard), where an exhibition will be organised. During the afternoons various addresses will be given. In the mornings a well-considered programme has been drawn up, which provides for attendance at practical demonstrations at the clinics of the Faculty of Medicine and in the public and private hospitals and scientific institutes. Further particulars may be obtained from Mr. Léon Tixier, 18, Rue de Verneuil, Paris (7e).

Obituary.

SIR ALEXANDER OGSTON, M.D. ABERD., K.C.V.O.,

LATE REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF ABERDEEN.

ON Feb. 1st the medical profession lost by the death of Sir Alexander Ogston an eminent surgeon and a veteran leader. He devoted his life to the promotion of scientific surgery, realising throughout that the medical profession, if it were to serve properly the public needs, alike in civil and military circumstances, must be properly organised, so that evolving professional knowledge could be rendered available in a prompt and orderly way.

Ogston, who was 84 years of age at the time of his death, had been living in retirement for some years. He was the eldest son of Prof. Francis Ogston, professor of forensic medicine at Aberdeen, and was educated at his home University, where he graduated M.B., C.M. in 1865, being then just short of his twenty-first birthday, while he also attended a certain number of medical courses in Glasgow. He then made a prolonged continental tour, obtaining post-graduate instruction at Paris, Vienna, and Berlin, proceeded to the degree of M.D. at Aberdeen with the shortest possible interlude, and went abroad again to follow up various studies in the leading medical schools. With such a grounding and substantial family introductions, success came rapidly to him on return to his native city, and we are reminded by what actually occurred of the all-round capacities expected of and displayed by the promising young doctors 60 years ago. Ogston's ophthalmological work in foreign clinics obtained for him almost immediately the position of ophthalmic lecturer in the University of Aberdeen; at the same time he made a promising start as a general operating surgeon; while from 1866 to 1873 he acted as assistant to his father, specialising in medical jurisprudence. Nor did this round off his energies, for from 1868 to 1872 he was joint medical officer of health for Aberdeen, in the latter year being superintendent of the Small-pox Epidemic Hospital set up in the city. In 1870, while still lecturing on ophthalmoscopy in the University, he was appointed junior surgeon at the Royal Infirmary, and four years later became full surgeon, reaching the position of senior in 1880. He was senior surgeon to the Royal Infirmary for the following 18 years, when he was appointed consulting surgeon. This extended connexion with the infirmary synchronises, it will be seen, with the enormous revolution in surgery brought about by Lister's discovery, for Ogston served his apprenticeship in those days, so often described in lurid terms, when hospital wards, despite the skill of individual surgeons, were nests of foulness. The new and fundamental knowledge came in time for those who could seize immediately upon its meaning, and Ogston began at once to display his qualities as a successful operator on modern lines, and was actually a pioneer in the pathology of septicæmia, as is shown below in Prof. Bulloch's estimate of his teacher. With the extended range of surgery made possible by the Listerian methods, Ogston became a fine operator; he specialised in bone surgery and for a long time "Ogston's Operation" was the classic procedure in genu valgum. In 1882 he was appointed Regius Professor of Surgery in the University and held this post for 27 years, retiring in June, 1909, an event which was celebrated by the presentation of public addresses and of portraits by Mr. Fiddes Watt painted, one for the University, and one for the Ogston family.

SIR ALEXANDER OGSTON.

Morgan Studios.

In the public eye Ogston was closely identified with military surgery, and for very good reason. His experience here must have been unique for one whose extensive and varied service in the field was unsupported by any special training as a military officer. His interest in the training of medical men for service in the fighting forces was unceasing, and he was acclaimed by a well-known Director-General of the Navy as "the first pioneer in dealing with the medical conditions prevailing in the Army and Navy in modern times . . . work he did without fee or reward." In his own book, entitled "Reminiscences of Three Campaigns," we have his experiences of the Franco-German War (1870–71), the Egyptian War (1884–85), and the great European War, while he also saw service in the South African War. What he saw in the first two campaigns made of him a severe critic of the existing military and naval organisations, and some of the experiences which he gathered in the last decade of his life in Serbia, and later in Italy, appeared to him to support his earlier opinions. It was particularly in the Egyptian War that he had first-hand opportunities of mastering the details of military surgery, and for his services and personal bravery he was awarded the Khedive's Bronze Star and the Egyptian war medal. He was elected member of the Committee of Medical Experts appointed by the Government in 1901 for the future organisation of the Royal Army Medical Corps, the appointment being determined by his publicly expressed opinions at the annual meeting of the British Medical Association at Portsmouth, some two years previously, on the inefficiency of the R.A.M.C. Thirteen years later, although already over 70 years of age when hostilities broke out, he made unceasing efforts to get to the front, and actually succeeded in seeing active service in Serbia, and discharging important duties with the Italian Army. His experiences, therefore, gave him a right to hold fine opinions on the right way to secure medical officers to minister to the Navy and Army, and while his great scheme for removing these officers from departmental control received no general support, many of his suggestions have been adopted.

Prof. WILLIAM BULLOCH writes:—"The announcement of the death of my old and revered teacher, Alexander Ogston, has prompted me to place on record a modern appreciation of his pioneer bacteriological work on inflammation and suppuration. It is not generally recognised that many of the current doctrines of infection and metastatic generalisation of bacteria really emanated from him. Prior to 1880 there was a condition bordering on chaos with regard to the nature of the conditions which were described as septic infection, pyæmia, and septicæmia. As late as 1879 the Pathological Society of London held a prolonged inquiry on the subject and showed that our knowledge was in the highest degree incomplete and the opinions discordant. The modern views of the relation of putridity to septicæmia were developed by Koch (1878) in his small but epoch-making book on the 'Ætiology of Traumatic Infective Diseases.' This work, written while Koch was still a practitioner

in Wollstein and far removed from academic influences, is a landmark in bacteriology. Koch's object was to determine whether infective processes in wounds were parasitic or not. He had to confine himself exclusively to animal experiments, but was able to show in a manner amounting almost to proof that a series of diseases differing clinically, anatomically, and ætiologically can be produced experimentally by the injection of putrid fluids into small animals. Koch used methods of investigation which were then new. Fluids and tissues were stained by anilin dyes and the films and sections were examined by the aid of the illuminating apparatus devised by Abbé, in combination with the admirable oil-immersion lenses made by C. Zeiss.

"The application of these methods had an enormous and lasting influence in the development of bacteriology. Although Koch's original intention was to study the infection of wounds in man, he was not in a position to do so and thus a considerable hiatus was left in his work. This hiatus was filled in an exact fashion by Alexander Ogston, at that time (1880–81) assistant surgeon in the Aberdeen Royal Infirmary. Following Koch's technique exactly, Ogston examined for bacteria over 100 abscesses, of which some were 'cold' but most were 'acute.' No micro-organisms could be found in the former, whereas in all the latter, micrococci were demonstrated and were found to be arranged either in groups like the roe of fish or in chains. He showed that this difference in appearance was due to a fundamental difference in the mode of fission. By patient hæmocytometric studies he estimated the proportion of the pus cocci to the pus corpuscles. He described and figured the occasional occurrence of bacteria other than cocci in abscesses, and described, for example, fusiform bacilli and spirochætes in alveolar abscesses long before they were noted by others. By experiments on mice Ogston then showed that pus which contained cocci could produce abscesses, and in the resulting pus he found, by means of the hæmocytometer, that the cocci had greatly increased in numbers. Pus heated or treated with phenol had no power to produce inflammation. He was therefore led to believe that the cocci were actually alive—a point which at that time was not universally accepted. Ogston made over a hundred attempts to cultivate the cocci in vitro and tried aerobic and anaerobic conditions. He ultimately succeeded best with cultures made in eggs and showed that these cultures were capable of producing abscesses in animals. From these experiments he formulated certain general conclusions. He considered that at first the cocci proliferate locally and may invade peripherally. They may even pass into the blood. In abscesses they were excluded by the formation of a deliminating wall of granulation tissue which arrested their further spread.

"In 1882 Ogston published further conclusions on 'micrococcus poisoning.' He herein emphasised the difference between the chain and group cocci. For the former he retained Billroth's name 'streptococcus,' and for the latter Ogston introduced (at the suggestion of W. D. Geddes, the professor of Greek in Aberdeen) the name staphylococcus. Ogston connected local coccal infections and spreading phlegmons ending in pyæmia and septicæmia as part and parcel of the same process and as being due to differences in degree rather than quality. He opposed the prevailing view that pyæmia and septicæmia were 'blood' diseases, and showed clearly that blood was merely the vehicle which may generalise in the body what without its aid would be only a local process. Ogston contended that pyæmia and septicæmia were the sequence of local foci of micrococcus growth and were merely the expression of the malign influences coming from this source. In his opinion the variations in the course and termination of infective processes were brought about by differences in the microbes, their virulence, the organ or structure involved, and the susceptibility of the individual affected.

"Ogston's publications, advanced and original as they were, rapidly exerted an influence on the surgical, bacteriological, and pathological teaching on inflammation and suppuration. Lister (1881) opposed some of Ogston's views, but the latter defended himself skilfully with new arguments and, as it happened, practically every word he wrote has turned out to be correct and is accepted teaching of to-day. Ogston's work on 'micrococcus poisoning' was remarkable not only from its accuracy of observation, but also from the correct interpretations which he made. As the science of pathogenic bacteria was gradually emerging between 1876 and 1886, almost nothing was done on the subject in England. France and Germany were very active and the technical methods of Koch were leading to a marvellous harvest of results. Apart from David Bruce's discovery of the agent of Malta fever, and that was of a later date, Alexander Ogston was the only worker in England who now finds a permanent place in the history of pathogenic bacteriology in its classical period. His observations and views have all passed so much into common knowledge that only his death in 1929, half a century after his work was published, serves to remind us of the man who correctly interpreted the exact ætiology of acute suppurative processes in man."

Inevitably Sir Alexander Ogston in the course of his long and distinguished career received many honours. He was Surgeon in Scotland to Queen Victoria and King Edward VII., and Surgeon-Extraordinary to the present King; he was an LL.D. of the Universities of Glasgow and Aberdeen; an ex-President of the B.M.A., a Knight of the Order of the Crown in Italy, D.L. for Aberdeenshire, and in 1912 was created K.C.V.O. He was twice married, first to Mary Jane, daughter of Mr. James Hargreave, by whom he had two sons and two daughters, and secondly to Isabella, daughter of the late James Matthews, Lord Provost of Aberdeen, by whom he had four sons and four daughters.

JOHN OWEN, M.D., F.R.C.P. LOND., D.P.H. CAMB.

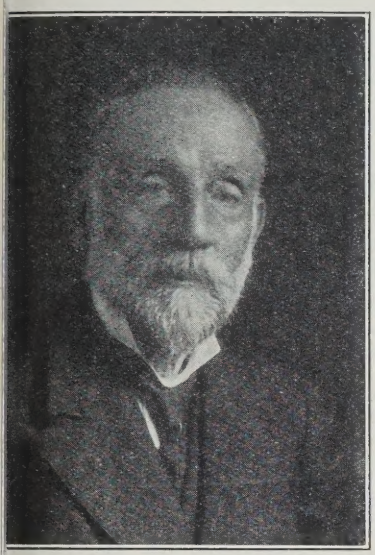
By the death of Dr. John Owen, who succumbed on Jan. 31st to an acute attack of pneumonia, Liverpool loses one of its best known physicians. Born in 1871, John Owen was educated at the Beaumaris Grammar School and at the University Colleges of Bangor and Liverpool, proceeding to Guy's Hospital for his medical training. He qualified M.B. Lond. in 1897, becoming M.D. in 1906, M.R.C.P. in 1908, and F.R.C.P. in 1923. He returned to Liverpool on qualification to a post at the Royal Southern Hospital and then started in general practice, but on the outbreak of the South African War he joined the staff of the Portsmouth Military Hospital as civil surgeon and later served in South Africa. On his return he held a post as medical officer to St. Pancras Dispensary before returning to Liverpool as consulting physician. He became attached in an honorary capacity to various hospitals and institutions, including the Liverpool Royal Infirmary; the Home for Epileptics, Maghull; the Eye and Ear Hospital, Liverpool; Southport Infirmary; and the Liverpool Hospital for Consumption and Stanley Hospital, and was at one time physician and pathologist to the Northern Hospital. He was also lecturer in clinical medicine at Liverpool University. Dr. Owen served in India and Mesopotamia during the Great War, retiring with the rank of Major in the R.A.M.C. Territorial Force and the Territorial Decoration. He was as renowned as a physician as he was liked as a man. His sympathy with patients and steadfast loyalty to his colleagues endeared him to all who knew him. He was interested in neurology as well as in the heart and lung, and was keen to detect unusual symptoms and to appreciate diagnostic points. His death will be regretted by all who came under his influence at the Liverpool Medical School and elsewhere.

FRANCIS DE HAVILLAND HALL, M.D., F.R.C.P. Lond.,

CONSULTING PHYSICIAN TO THE WESTMINSTER HOSPITAL.

We announced last week the death, after a short attack of pneumonia, of Dr. Francis de Havilland Hall, which occurred at his house at Twickenham on Sunday, Jan. 27th, in his eighty-third year.

Few physicians in London were better known to his colleagues throughout an extended period of consulting practice than de Havilland Hall. He was born in Hatfield on April 10th, 1847, the son of Dr. W. Hall, and after general education at Bruce Castle School, Tottenham, received his medical training at St. Bartholomew's Hospital. He qualified as M.R.C.S. Eng. and L.S.A. Lond. in 1868—the usual double qualifications at that date—and graduated in medicine in the University of London in the following year. At St. Bartholomew's Hospital he held the regular residential posts, and was then appointed casualty physician, being also elected assistant physician to the Metropolitan Dispensary. For a brief time he went into general practice, but at this point his association with Westminster Hospital started, and continued for over 40 years. In 1876 he was elected medical registrar at the institution, and almost immediately afterwards assistant physician in charge of the throat department, his contemporaries being, among others, Octavius Sturges, William Allchin, J. B. Potter, and Bryan Donkin. The result of his laryngeal work was evidenced by a short volume which he published in 1878 entitled a "Synopsis of the Diseases of the Larynx, Lungs, and Heart," but Hall was not only a specialist. In one direction, in particular, he displayed his all-round capacity—namely, by his work in connexion with life assurance. He became medical officer to the Law Union and, later, to the Rock Insurance Companies, and was particularly conversant with the special and general problems presented by this side of medicine. He served as President of the Assurance Medical Officers' Association, and throughout his long professional career was regarded rightly as an authority upon the principles of life assurance, while his manual entitled "The Medical Examination for Life Assurance" ran through three editions. His other writings were mainly the outcome of his charge at Westminster of the throat department of the hospital, for he contributed articles on diseases of the larynx and nose to Fowler's "Dictionary of Practical Medicine," and those on diseases of the nose and throat to Allbutt's "System of Medicine"; but he wrote upon diseases of the mediastinum in the "Encyclopædia Medica," and on diseases of the pleura and mediastinum in Allchin's "Manual of Medicine." All these contributions to medical literature were valuable because they were based upon long personal observation, but his work on the larynx and throat formed his principal claims to attention, and he was one of the original members of the old Laryngological Society. He served for no less than 20 years as assistant physician to the hospital, becoming full physician in 1896 and consulting physician in 1912.



DR. DE HAVILLAND HALL.

Elliott and Fry.

De Havilland Hall's association with the Royal College of Physicians of London was a close one. He obtained the M.R.C.P. while still at St. Bartholomew's Hospital, was elected F.R.C.P. in 1881, was Censor from 1908 till 1911, was an examiner in medicine for the licentiateship, and in 1913 delivered the Lumleian lectures when he took as his subject intrathoracic aneurysm. The lectures, which were published in THE LANCET, formed a scholarly and comprehensive history of the disease up to the date of delivery, and were based alike upon his own work and an evaluation of that of his predecessors and colleagues.

Mr. W. McAdam Eccles writes: "My friendship with Dr. de Havilland Hall was enhanced by mutual association with insurance problems. His opinion thereon was eagerly sought for, and almost universally acted upon. His long connexion with the Rock Insurance Company, and afterwards the Law Union and Rock, entitled his conclusions upon difficult questions to be listened to with respect. It was in connexion with the Life Assurance Medical Officers' Association (which later became the Assurance Medical Society) that he specially shone. He had read various papers before the Society, and seldom missed a meeting, generally adding considerable zest to the discussions by his cogent remarks upon the matter under review. In 1912 he was elected President of the Society, holding office for two years with great grace and energy. Some of the remarks which have fallen from him are almost in the nature of epigrams, and are worthy of quotation:—

> I have never been able to explain why so many of these obese people do not seem to be large eaters. I suppose really their digestive system is so thoroughly efficient that they assimilate all the nourishment they take, whereas lean people perhaps have not the same powers of assimilation.

> In the case of ——, who was operated on for chronic appendicitis, calcified mesenteric glands were found. His abdominal "Stonehenge" was doubtless due to old tuberculosis, but he has since remained in good health.

> I would insist on the use of the sphygmomanometer "in all applicants above the age of 50" (1912); now (1921) I should say over 40.

Mr. Walter Spencer, in an appreciation of a senior colleague, comments upon de Havilland Hall's long service at Westminster as an out-patient physician. "In consequence," he writes, "de Havilland Hall was led to adopt what became characteristic of his teaching—precise detail as to medical treatment and prescribing, categorical instruction after the manner an examinee must answer questions, various modifications of hospital practice necessary in private practice. Continued later in the wards, this system of teaching, in particular to students having general practice in view, by a physician of experience, was more beneficial than is such instruction in tutorial classes by junior colleagues. . . . Until he became full physician he conducted the laryngological department and with his close friends, Butlin and Felix Semon, was one of the founders of the Laryngological Society. He wrote a popular text-book, 'Diseases of the Nose and Throat,' and when a new edition was called for Mr. Herbert Tilley joined him and added much on surgery. The loss of de Havilland Hall from the consulting staff of Westminster Hospital, following immediately upon that of Mr. William Wroughton from the committee, has removed the last of the personnel as it existed when I was appointed 42 years ago—Hall kept up a continuous intimacy with many members of the St. Bartholomew's staff and I owed much to him for the introduction he gave me on my election. Throughout our time together we corresponded, physician with surgeon. He was quick in

coming to a diagnosis that a case would be benefited by medical treatment. Alternatively he was prompt and on very many occasions gave me the opportunity of operating early. His optimistic temperament had in recent years great trials. Chronic diabetes had to be kept in check and his personal tendency to abstemiousness both as to food and drink had to be yet more rigidly observed. Then came personal anxieties during the war, and then the sudden death of his special friend, Frederick Palmer, deprived him of the companion of his weekly walks. Finally, malum coxæ senile gave him much pain. When last we met, about a month ago in the board room, he with two sticks, hardly able to hobble a hundred yards, was still his cheerful self, reminiscent, and hopeful that the pain was passing off."

Dr. LINA POTTER, the daughter of Dr. de Havilland Hall's late colleague and intimate friend, writes: "Looking back on the man one feels that the keynote of his personality was size—he was large in mind as in his tall loose-made frame, and he was large in his appreciation, being easily noted in a crowded meeting for his hearty laugh and cheery bearing. He never said an unkind thing, an attitude due to no restraint of tongue but to the fact that he never had an unkind thing to record."

These excerpts from communications which we have received give a good picture of a man to be admired and regretted, and two directions may be mentioned in which he showed his great kindness, his love of his profession, and deep sympathy with his fellow practitioners. He was the President of the Society for the Relief of Widows and Orphans, and as a medical man was deeply interested in the prosperity of the Society and assiduous in bringing its advantages before his colleagues. He was also for 25 years on the Council of Epsom College, vice-chairman for three years, a regular attendant at the meetings, and until a few weeks ago was chairman of the selection committee for ten years. No voice was listened to at the Council with more respect than his, for his judgments were those of a fair but absolutely generous man.

Dr. de Havilland Hall married Amy Margaret, daughter of Apsley Smith, of Rusthall, Tunbridge Wells, and is survived by his widow, one son, and three daughters.

JOHN EDWIN EDDISON, M.D. EDIN., D.SC.

BY the death of Dr. Eddison, which took place at Cuckfield, Sussex, after 20 years' retirement from active practice, there passes one of the older generation of Leeds consultants who for many years took a leading position in the professional and intellectual life of the city of his birth.

John Edwin Eddison was born in 1842 at Headingley, the son of a well-known solicitor in Leeds. He received his medical edication at the University of Edinburgh, where he was greatly impressed by the thorough clinical teaching of Hughes Bennett and George Balfour. He graduated in 1864, taking the M.R.C.S. Eng. in the same year. He then studied in London and, for some little time both in Paris and in Vienna, before beginning practice in Leeds. From the first his aim was to be a consulting physician, and he got his chance towards the end of the seventies when Charles Chadwick, who was at that time senior physician to the General Infirmary, resigned, and Eddison was appointed to the staff, becoming junior colleague to J. D. Heaton and Clifford Allbutt. Some of the other medical charities of Leeds also had the benefit of his services; he was physician to the Public Dispensary, to the Women and Children's Hospital, and to the "House of Recovery," one of the first fever hospitals to be opened in this country, where diseases such as typhus and relapsing fever, now almost extinct, came under his notice frequently.

Eddison served the General Infirmary as physician for 21 years. Until 1884, when assistant physicians were appointed, he worked not only in the wards but in the out-patient rooms. He was keenly interested in the welfare of the school of medicine and took a large share in the teaching of the students. Dr. Wardrop Griffith, who followed him in both capacities, writes that Eddison's ward-teaching was always stimulating and suggestive if somewhat lacking in didactic qualities. Thus the men who got most benefit from being associated with him were the senior students, and especially those who had the pleasure of working under him as resident officers. "From some four years' intimate relationship with him I can testify that he was one of the pleasantest men with whom to work; he always gave one credit for doing one's best, and in this way he really did get the best out of his subordinates, who will always bear him in affectionate remembrance."

Eddison's intimate association with medical education in Leeds cannot be properly understood without some reference to the various stages in the development of the University. Although some lectures on medical and surgical subjects had been given in connexion with the infirmary (which was founded in 1767), the Leeds School of Medicine was founded in the year 1831 by the first William Hey, a pupil of John Hunter's, and the most outstanding personality in the history of the school. When the Yorkshire College of Science, which was founded in the very early seventies, enlarged its scope of work by inaugurating chairs in the humanities, an arrangement was made with the new college for medical students to get their pre-medical instruction there. In 1884 a more complete amalgamation between the two bodies took place and the way was paved for the Yorkshire College (which had now dropped its limiting title of "of Science") to affiliate with the Victoria University as one of its three constituent colleges. Dr. Eddison was appointed the first professor of medicine under the new régime. When in 1924 the University of Leeds (now becoming autonomous) celebrated its coming-of-age, Dr. Eddison was awarded the honorary degree of Doctor of Science.

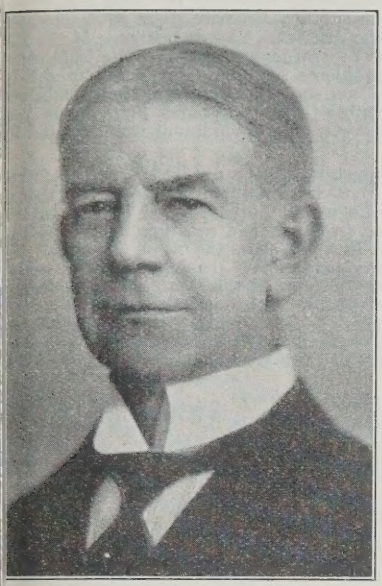
Outside his purely professional life Dr. Eddison was a man of varied culture. He was curator and four times president of the Leeds Literary and Philosophical Society, and on the Council of the Yorkshire Archæological Society. He was a great reader and had a most retentive memory; he was a man of great natural ability; his mind was nimble, alert, and keenly critical. In the opinion of many it was this very hypercritical frame of mind—which in justice it must be said he applied to his own observations and views as well as to those of others—that stood in the way of his contributing as much to the advance of medical science as his great abilities would have seemed to warrant. Eddison was one of the founders of the Leeds Trained Nurses' Institution. He was a magistrate for the West Riding and from 1908 to 1913 hon. colonel of the West Riding Division R.A.M.C. (T.).

Dr. Eddison married Elizabeth, eldest daughter of Mr. John Dougill, of Huddersfield, who survives him without issue. His body was taken back for burial to Adel Churchyard, where there was a large gathering of his old friends and colleagues, with representatives from the University of Leeds and the various bodies on which he served.

CHARLES HUBERT ROBERTS, O.B.E., M.D., F.R.C.P. LOND., F.R.C.S. ENG.

WE regret to record the death of Dr. C. Hubert Roberts who was well known in London as an obstetrician and gynæcologist. Roberts had suffered from failing health for the past year or two and had been advised to take long sea voyages. It was on one of these trips that he had to be landed in Denmark owing to an acute attack of influenza contracted in London some few days previously. He died on Jan. 29th in the sixty-fourth year of his age.

After leaving school at Bedford, Roberts entered the Medical College of St. Bartholomew's Hospital, where he had a distinguished career. Amongst his many successes he carried off the Junior and Senior Scholarships in Clinical Medicine and also the Brackenbury Scholarship in Surgery. Qualifying in 1889, he took the Fellowship of the Royal College of Surgeons in 1892 and won the Gold Medal in the London M.D. in 1896. For some years after qualification Roberts continued to work at his alma mater first in three successive resident posts, later as casualty physician, assistant demonstrator of anatomy in the school, and tutor in midwifery and diseases of women. In the latter capacity he proved to be a most successful examination coach, and when he resigned his appointment he held the record for distinctions gained by his pupils. On leaving St. Bartholomew's Dr. Roberts was appointed to the staff of Queen Charlotte's Hospital and the Samaritan Free Hospital, to which institutions he devoted the best part of his life, retiring only on attaining the age-limit four years ago. He was an active member of the Obstetrical Society and afterwards did his full share of sectional work at the Royal Society of Medicine, where he filled the offices of librarian, junior and senior secretary, and finally was made one of the vice-presidents of the Section of Obstetrics and Gynæcology. In 1910 Dr. Roberts was elected a Fellow of the Royal College of Physicians, and in due course he became an examiner on the Conjoint Board and also in the University of Sheffield and on the Central Midwives Board. He was not a voluminous writer on clinical subjects, but he wrote a useful book on gynæcological pathology and translated Orthmann's small text-book on the same subject. His illustrations in his own text-book and those he executed for some of his colleagues are of high artistic merit; indeed, at one time he had serious intentions of devoting himself entirely to art.



DR. C. HUBERT ROBERTS.

Roberts was a man of modest disposition, and this may, in some measure, have circumscribed his circle of acquaintances; but those who knew him in his work recognised him as an able diagnostician and a highly skilled obstetrician. He had a genial temperament and before his health failed used to delight in entertaining his friends at his club, and in his leisure hours enjoyed exploring the Thames valley in his motor-car, using his house at Taplow as a base.

A COVENTRY CONVALESCENT HOSPITAL.—Lady Haig last week opened, and the Bishop of Coventry dedicated, the Alcock Convalescent Hospital at Keresley Hall on the outskirts of Coventry as an adjunct to the Coventry and Warwickshire Hospital. The cost of the purchase and equipment were provided by a legacy of £11,000 left by the late Mr. John Alcock. There are 40 beds, and patients will be removed to Keresley as early as possible so that the long waiting-list of the main hospital may be shortened.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT BILL.

ON Wednesday, Jan. 30th, the House of Commons went into Committee on the Local Government Bill. Captain BOURNE, Temporary Deputy Chairman of Committees, was in the chair.

Power to Remove Difficulties.

Clause 111 provides that—

"if difficulty arises in connexion with the application of the Act to any exceptional area, or in bringing into operation any of the provisions of the Act, the Minister may by order remove the difficulty or make any appointment, or do any other thing, which appeared to him necessary or expedient for bringing the said provisions into operation, and any such order may modify the provisions of this Act as far as may appear to the Minister necessary or expedient for carrying the order into effect."

Mr. G. B. HURST moved an amendment which he said raised an important constitutional issue because the effect of the clause was to delegate the sovereign powers of legislation to a Government Department. It was true that that delegation was for a limited period, but the fact remained that it was another illustration of the modern practice of Parliament of handing over its powers to departmental control. He moved to omit certain words from the clause with the object of restricting the powers proposed to be given.

Sir H. SLESSER, who supported the amendment, said that it reminded him of the Statute of Proclamations of King Henry VIII., which said that anything which was enacted by the King in Council should have the force of law.

Mr. CHAMBERLAIN (Minister of Health) said that the clause to which objection had been taken had behind it a great weight of precedent. This was no new provision. It was to be found in the Local Government Acts of 1888 and 1894; in the National Insurance Act, 1911; in the Unemployment Insurance Act, 1920; in the Widows', Orphans' and Old Age Contributory Pensions Act, and in the Rating and Valuation Act. There must be some such provision to avoid the necessity for bringing in an amending Bill every time any change was necessary. No case had arisen under clauses of this kind where Parliament had had cause to complain of its abuse.

Sir LESLIE SCOTT said he hoped that the Minister of Health before the report stage would consider whether he could not alter the wording of the clause so as to attain its object whilst avoiding the dangers of which many were now conscious.

Sir A. HOPKINSON said that they had had too much of substituting Ministerial Orders or Orders of a Department for Acts of Parliament.

Mr. RYE said that the Law Society regarded this clause with grave apprehension.

After further debate,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) promised that before the report stage the various suggestions that had been put forward during the debate should be considered with a view to amending the clause to bring it into conformity with what they all desired.

The amendment was thereupon withdrawn.

Sir KINGSLEY WOOD moved a new clause which he explained provided that before the expiration of the second fixed grant period the Minister in consultation with the local authorities should cause investigation to be made into the working of the formula and the scheme of county distribution.

The clause was read a second time and added to the Bill.

Sir KINGSLEY WOOD moved a new clause which he said gave effect to an agreement made with the local authorities in the following terms:—

It is hereby declared that it is the intention of this Act that in the event of substantial additional expenditure being imposed on any class of local authorities by reason of the institution of a new public health or other service after the commencement of this Act provision should be made for increased contributions out of moneys provided by Parliament.

The clause was carried by 188 votes to 96.

Sir KINGSLEY WOOD moved a new clause dealing with contributions to voluntary associations and introduced to meet the criticism that a voluntary association covering the whole of the country would be obliged to collect small sums from a large number of counties and county boroughs.

The new clause, he said, empowered the Minister, if application was made to him by the counties and county boroughs concerned, to make one payment on behalf of the councils to the association concerned in regard to services relating to maternity and child welfare, lunacy, mental deficiency, and the welfare of the blind, out of the sums payable as the general Exchequer grant.

Dr. VERNON DAVIES asked whether it would be necessary for the county to make application to the Minister every year or whether they could do so for a fixed period or until notice of cancellation?

Sir KINGSLEY WOOD said that he would consider what was the best arrangement. When the Act came into force it was the intention of the Minister of Health to address general communications to the local authorities concerning it, and in one of those communications attention would be directed to this clause.

The clause was read a second time and added to the Bill.

Sir KINGSLEY WOOD moved the following new clause dealing with special provisions as to the functions of poor-law authorities in respect of infant life protection and vaccination:—

As from the appointed day the following provisions shall have effect with respect to functions relating to infant life protection and vaccination formerly discharged by Poor-law authorities:—(*a*) Functions under Part I of the Children Act, 1908, shall, elsewhere than in the county of London, be discharged by the councils of counties and county boroughs as functions under the Maternity and Child Welfare Act, 1918, except that where the council of a district have established a maternity and child welfare committee the said functions shall, in that district, be discharged by the council of the district and not by the county council; and (*b*) Functions relating to vaccination shall be discharged by the councils of counties and county boroughs as functions relating to public health.

He said that this new clause was to make special provision for the functions of poor-law authorities in regard to infant life protection and vaccination. It was necessary to ensure that the functions in regard to those subjects were imposed upon the appropriate authorities and exercised by their appropriate committees. These functions were at present discharged by boards of guardians under Part I. of the Children Act, 1908, and the Vaccination Act respectively. In the absence of any special provisions they might be transferred to county and county borough councils on the appointed day. Therefore it was proposed that the exercise of these functions in all cases should be undertaken by the maternity and child welfare authorities. It was thought that it would be more satisfactory to give the work to those authorities who employed health visitors, the bulk of whose work related to children under 5 years of age. As regarded London, it was not necessary to make any special provision, since the London County Council and the City Corporation were already authorities under Part I. of the Children Act, 1908. In clause 52 of the Bill it would be found that there was power given to the London County Council to transfer their functions to the metropolitan borough councils subject to the making of the necessary application to the Minister. As regarded vaccination, the duties of boards of guardians under the Vaccination Act were in the nature of public health functions and had nothing whatever to do with the relief of the poor. The effect of paragraph (*b*) of the new clause would be to secure that the functions relating to vaccination should be discharged by the county and county borough councils as public health functions, and all matters relating thereto were referred to their health committees instead of to the public assistance committee. Special provision for vaccination work in London was contained in clause 15 (*f*) which provided that this work should be transferred from the boards of guardians to the common council of the City of London and to the councils of the metropolitan boroughs instead of to the London County Council. This provision was in accordance with the wishes of the county council and the borough councils.

The clause was read a second time and added to the Bill.

The committee stage of the Local Government Bill was concluded in the House of Commons on Friday, Feb. 1st, which was the thirteenth and last allotted day allowed under the terms of the Guillotine Resolution.

LOCAL GOVERNMENT (SCOTLAND) BILL.

ON Monday, Feb. 4th, consideration of the Local Government (Scotland) Bill was begun in Committee.

Transfer of Functions.

On clause 1, which provides for the transfer of functions of parish councils and district boards of control to county councils and town councils of large burghs, Sir A. SINCLAIR moved the deletion of the provision relating to the parish councils. Sir J. GILMOUR said that the new central authorities to be set up would be the elected representatives of the people, charged with certain duties, but it was clearly indicated that those bodies should submit definite schemes showing in detail how they would carry out their duties. In the case of the poor-law it was obvious that there must be within these schemes such measure of arrangement as would insure that immediate relief was given to the necessitous people within the district. The real essence of the Bill was that there should be a large amount of elasticity in order that the peculiar problems of particular areas might be dealt with. Dr. ELLIOT, replying to a question, explained that it would be possible to treat the sick poor under Act other than the poor-law. The amendment was defeated by 193 votes to 94.

Sir J. GILMOUR, speaking of the duties to be transferred from parish councils to district councils said that a number of amendments which he would move carried out an undertaking which he gave on the second reading. The duties to be transferred were, in the main, the same duties as the parish councils were performing to-day, with certain exceptions. The chief exception was that of the poor-law but in the matter of dealing with outdoor relief the central body might under their scheme delegate some part of the work to the district councils. The amendments, moved by Sir J. Gilmour, were afterwards carried, and the clause added to the Bill.

On clause 2, which deals with the transfer of certain other functions to the county councils, Dr. SHIELS moved the omission of para. (*b*), which transfers the functions of town councils of small burghs within the county as local authorities for the purposes of the statutory provisos set out in Part I of the First Schedule. (Part I. includes the Infectious Diseases (Notification) Act, the Public Health (Scotland) Acts, 1897 to 1907, so far as relates to infectious, epidemic, and endemic diseases, buildings for post-mortem examinations, vaccination and unsound food, and the Notification of Births Acts, the Midwives (Scotland) Act, the Venereal Disease Act, 1917, Section 4 of the Maternity and Child Welfare Act, 1918, the Public Health (Scotland) Amendment Act, 1925, Midwives and Maternity Homes (Scotland) Act, 1927, and the Food and Drugs (Adulteration) Act, 1928.

Dr. SHIELS said that the proposal did not seem to have any justification and had no relation to the de-ratin proposals. The small burghs had for hundreds of years been places of efficient government. Sir J. GILMOUR replied that it was not the case that the county councils were inefficient. The small burghs would under the Government's scheme play a very large and important part in the policy and administration with which the new larger authorities would be entrusted. The amendment was rejected, and the clause added to the Bill.

On Tuesday, Feb. 5th, consideration of the Scottish Bill was resumed in Committee. On Clause 3, Sir R. HAMILTON moved to omit the subsection providing for the transfer of the functions of the education authorities.

Reply to the Debate.

Dr. ELLIOT, replying to the debate, said that at this moment a recasting of local government was taking place in Scotland, and they expected an extension and enlargement of the powers of the central bodies—the county councils and the town councils—to take place which would raise them to a position of prestige and dignity which they have never enjoyed before. Their hands were being freed by new grant to a very large extent from many of the niggling controls which it was necessary to place on them when the system of the percentage grant was introduced. Furthermore, in the health clauses, the Government were making it possible to alter the health system of Scotland along the line which the health reformers had been demanding now for many years past. When all these great changes were taking place it would be folly and criminal to leave out of account the 8,000,000 school-children who were the very flower of Scotland. The time had gone past when it was possible to treat the mind of the child apart from the body of the child. They must have the close and intimate connexion of the great new authority which was responsible not *ad hoc* for health but *ad omnia*, as health was one of the major functions; if health was not too important a subject to put into the hands of this great new authority, the education was not too important either. If they could entrust this new authority with the terrible and powerful responsibility of tender years of child life of Scotland from 1 to 5, and with the life of the adults of Scotland from school age to death and the bodies of Scotsmen and Scotswomen, it would be going back on all that they were bringing forward and on the whole period of health as one of the most important of modern function to say that the body was the secondary thing and that an *ad omnia* authority can take charge of the bodies of the people of Scotland, but that in respect of this question of

book learning there was something so sacred that it had not to be removed entirely from the ambit of that authority and to be put under different control. The Government's theory and conviction was that the body was as sacred as the mind, and if they could make a strong, fit, and burly generation of young Scots then they would have done something to which the making of the mind of the Scotsman and Scotswoman was not a secondary thing. That is their contention, and it was the contention of the great medical school—call it if they would a materialistic ideal, but the Government did not regard it as such.

The amendment was defeated and the clause agreed to.

Clauses 4, 5, and 6 were agreed to under the guillotine; also Clause 7, which provides for the transfer of officers and superannuation funds.

CORONERS ACTS AMENDMENT BILL.

On Wednesday, Jan. 30th, Mr. MORRIS asked for leave to bring in a Bill to amend the Coroners Acts, 1887 to 1926. He said that as the law stood, where a coroner's court had assembled and a person had been arrested and brought before a magistrate the coroner must, unless he had good reason to the contrary, adjourn the inquest. If the person was charged on an indictment and acquitted on the re-assembling of the coroner's court the jury could not find a verdict against that person, but if the charge was dismissed by the magistrate the jury could find a verdict against the person who had been discharged by the magistrate. A case had arisen at Oxford Assizes in the previous week where such a person after being acquitted by the magistrates was not only again placed in the dock, but had to bear all the expenses of his defence, in addition to which the country had to bear the expense of the attendance of numerous witnesses who were involved in the case. Such a position was illogical and the object of the present Bill was to amend the law accordingly.

The Bill was brought in and read a first time.

DISTRESSED AREAS.

On Feb. 4th Lord EUSTACE PERCY informed Mr. LANSBURY that in Northumberland and Durham £6000 had been placed at the disposal of the medical officers of health of the two countries for supplementary nourishment of mothers.

HOUSE OF COMMONS.

WEDNESDAY, JAN. 30TH.

Disablement in the Navy.

Mr. ROBINSON asked the First Lord of the Admiralty the number of ratings, and the percentage to the total strength, invalided out of the Navy in each of the years ending December 1922, 1923, 1924, 1925, 1926, 1927, and 1928, and the number in each year that were granted disability pensions.—Lieut.-Colonel HEADLAM gave the following figures:—

Year.	Number Invalided.	Percentage to total strength.	Number awarded disability pensions.
1922 ..	2,028	2	379
1923 ..	1,474	1·6	322
1924 ..	1,330	1·5	543
1925 ..	1,517	1·7	522
1926 ..	1,726	1·9	561
1927 ..	1,342	1·5	442
1928 ..	1,242	1·3	402

Spectacles for School-children.

Mr. DAY asked the President of the Board of Education how many children had been fitted and supplied with spectacles in England by the education authorities during the previous 12 months, and whether any, and, if so, how many of these authorities had the advantage of an experienced oculist.—Lord E. PERCY replied: The number of children provided with spectacles in England, under arrangements made by the education authorities during 1927 (the latest period for which returns are available), was 120,413. Out of 288 authorities in England 286 have the services of an experienced oculist.

Dangerous Drugs Traffic at Hong-Kong.

Mr. CECIL WILSON asked the Secretary of State for the Colonies why the import of raw opium from India into Hong-Kong rose from 11,998 kilogrammes in 1926 to 17,089 kilogrammes in 1927; and what the consumption of Government opium amounted to for each of the last five years per head of the Chinese population of Hong-Kong.—Mr. AMERY replied: The opium imported into Hong-Kong from India in 1927 was the authorised amount under the system of restricted exports introduced by the Government of India as from that year. It was based on the average imports of the previous five years, and happened to be greater than that for 1926 because in that year imports were considerably below the average. The consumption of Government opium in Hong-Kong per head of the estimated Chinese population, for the last five years for which figures are available, was: 1923, 0·51 oz.; 1924, 0·47 oz.; 1925, 0·31 oz.; 1926, 0·26 oz.; and 1927, 0·39 oz.

Mr. CECIL WILSON asked the Home Secretary whether his attention had been called to the document O.C. 877, presented a few days ago to the Opium Advisory Committee of the League of Nations, now sitting in Geneva; how the 734 kg. of heroin seized in Hong-Kong in 1924 and brought to Great Britain for disposal were disposed of, and what quantities of this drug had when seized been disposed of during the last five years.—Sir W. JOYNSON-HICKS replied: Yes, Sir. The heroin referred to was sold in this country in 1924 to persons duly authorised under the Dangerous Drugs Acts and Regulations to possess heroin. The total quantity of heroin seized and brought to this country for disposal from 1924 to date was 38,549 ounces. It was all disposed of to persons licensed under the Acts.

THURSDAY, JAN. 31ST.

Supplies of Radium.

Mr. ROBERT MORRISON asked the Minister of Health the quantity of radium at present in this country which was not being used, and who were the owners.—Mr. CHAMBERLAIN replied: I have no means of obtaining full information on this subject. Certain supplies of radium are in the hands of voluntary institutions and private persons. The uses of radium are not restricted to therapeutic purposes, and it rests with those to whom the supplies belong to secure their economical full usage.

Mr. MORRISON: In view of the difficulties which are being caused by local authorities and hospitals endeavouring to purchase radium, will the right hon. gentleman consider the advisability of taking action in order that these bodies may not compete against each other for the radium?

Mr. CHAMBERLAIN: I have told the hon. Member that this matter is under consideration by a special committee whose report I am expecting to receive very shortly.

Assessments of Voluntary Hospitals.

Sir ARTHUR HOLBROOK asked the Minister of Health if he had received complaints as to the large increases recently made in the assessments of voluntary hospitals; and whether, having regard to the benefits conferred on the community by these institutions and the financial difficulties under which many of them were suffering, he would consider the exemption of all voluntary hospitals from local rates.—Mr. CHAMBERLAIN replied: I have received some representations on this subject. The exemption of hospitals from rating could not be effected without legislation, and in my opinion any such proposal cannot be considered apart from the similar claims made on behalf of other charitable and public institutions.

MONDAY, FEB. 4TH.

Nursery Schools.

Mr. HARRIS asked the President of the Board of Education what progress had been made in the organisation of the nursery schools during the last 12 months; and if any new ones had been started during that period.—Lord EUSTACE PERCY replied: One new nursery school has been opened during the last 12 months; two schools are in course of erection. I have approved in principle the provision by the county council of two new schools in London. and I have also received an application for the recognition of a school in London under voluntary management. Four proposals by local authorities, and one by a voluntary body of managers, in the provinces are also under consideration.

Asbestosis.

Mr. W. THORNE asked the Home Secretary if his attention had been called to the prevalence of asbestos of the lungs among young girls employed in asbestos works and which had been diagnosed as asbestosis; if he was aware that cases had been admitted to St Thomas's and the London Chest Hospitals with this complaint; whether he had any record of the number of these cases; and whether he intended to schedule this disease under the Workmen's Compensation Acts.—Sir W. JOYNSON-HICKS replied: The Senior Medical Inspector of Factories reports that while he

is aware of cases of so-called asbestosis of the lungs among women, the effects of asbestos dust are already the subject of a comprehensive inquiry by the medical inspectors, which is being pushed forward as rapidly as possible. As soon as the results of this inquiry are available the question of applying the Workmen's Compensation Act will be considered.

Artificial Silk Industry.

Mr. KELLY asked the Home Secretary what decision he had arrived at in the matter of placing under the Workmen's Compensation Act certain operations in the artificial silk industry as coming under the industrial diseases section.—Sir W. JOYNSON-HICKS replied: I would refer the hon. Member to my reply on May 17th last and to my correspondence with him in September, when I explained the whole position very fully. No fresh facts have since been brought to my notice which would lead me to modify the views then expressed. The only two specific ailments which have so far been brought to my notice in connexion with the artificial silk industry are conjunctivitis of the eyes and sores on the hands, which are sometimes caused by the acid. As regards the conjunctivitis there do not appear to be any sufficient grounds for scheduling this disease. Compensation is not payable under the Act unless the worker is disabled for at least three days, and I am advised that even the severer cases of this affection do not as a rule disable the workman for more than one or two days and that where in exceptional cases it has caused more prolonged disablement it has been due to actual splashes of the acid into the eye, which would constitute an accident within the meaning of the Act. The sores on the hands would appear to be covered by the diseases already scheduled under the Act as dermatitis or ulceration of the skin produced by dust or liquids, but these sores, if treated promptly, should not incapacitate the workman.

A Child's Tonsils.

Mr. VIANT asked the President of the Board of Education whether he was aware that the education authority of Wolverhampton recently initiated a prosecution against Ernest Henry Gwinnett for cruelty to his daughter Gertrude Lily, aged 6, by failing to provide adequate medical aid in the matter of enlarged tonsils; that the only evidence tendered for the prosecution was that of three school medical officers and a schoolmistress; that the senior medical officer stated that the only remedy possible was a surgical operation; that a conviction was recorded; that, on an adjournment, as a result of the intervention of a local branch of the Distributist League, Mr. Gwinnett was represented, and two qualified London physicians in person, two more by affidavit, and one by certificate testified that the child was not suffering and that alternative treatment was practicable; and that this case was concluded on payment of a nominal fine of £2 without costs on an undertaking being given that treatment should continue; whether any expense had been incurred by the education authority.—Lord EUSTACE PERCY replied: I have seen a press report of the case referred to. I understand that it was stated on behalf of the local education authority that it was not their intention to force an operation on Mr. Gwinnett's child, and that all they required was that some treatment should be applied which would be as effective as an operation in curing the child. I have no information as to the expenditure, if any, incurred by the local education authority in connexion with the proceedings.

TUESDAY, FEB. 5TH.

National Health Insurance Control.

Mr. SHINWELL asked the Chancellor of the Exchequer whether he was considering an arrangement with any assurance companies for handing over control of the National Health scheme; and whether he would put the House in possession of all the facts.—Mr. CHURCHILL: I have seen this suggestion in a weekly journal. I gave a denial to it in answering a supplementary question put on Jan. 31st by the hon. gentleman the Member for Miles Platting. I am glad to have this opportunity of repeating the denial. The story is quite untrue. No such project has ever been brought before me or considered by me or by any of my advisers.

Influenza in Glasgow.

Mr. BUCHANAN asked the Secretary of State for Scotland if he was aware of the present epidemic of influenza in Glasgow and the increase of the death-rate arising from it; if his department had made special investigation into the cause; and, if so, what was the result.—Sir J. GILMOUR replied: As regards the first part of the question, I am aware that there is at present an epidemic of influenza in Glasgow, and a regrettably high general death-rate. There is an exceptionally high incidence of acute pneumonia, both primary and influenzal. As regards the second part, the Department of Health are in continuous touch with the Public Health Department of Glasgow, and are aware of the extent and efficiency of the measures taken in coöperation with the poor-law and voluntary hospitals to provide hospital treatment and nursing and medical care in the home. Notwithstanding the notification of nearly 1200 new cases of pneumonia in the week ended Jan. 31st, the waiting list has been cleared and the epidemic, it is believed, has passed the peak. As regards the last part, research into the causation of influenza, into its spread in epidemic form, into its pathology and into its remedy is being continuously pursued by workers in this and in other countries, and in this connexion the present outbreak is being watched and studied. I am of opinion that it is from research of this kind that the most useful results are to be expected.

Silicosis in the Sandstone Industry.

Mr. RENNIE SMITH asked the Home Secretary if he could furnish particulars of the proposed special scheme under Section 47 of the Workmen's Compensation Act, 1925, providing for compensation for silicosis for workmen in the sandstone industry; and if he could indicate the chief areas of the country, with the number of workmen involved.—Sir W. JOYNSON-HICKS replied: I am sending the hon. Member a copy of the draft scheme together with a copy of an explanatory letter issued to employers affected. I am also enclosing a copy of a report which has been published by H.M. Stationery Office, of a medical inquiry recently carried out for the Home Office and Mines Department into the occurrence of silicosis in the sandstone industry. The chief areas concerned are West Riding of Yorkshire Lancashire, North Derbyshire, and Durham and Northumberland. It is impossible to give accurate figures as to the number of workmen affected, but it is estimated roughly that the number will be not less than 11,000.

Mr. KELLY asked the Home Secretary if he would state the number of cases of disablement from silicosis which were reported during 1928; how many were partially disabled; the number permanently disabled; and the number of deaths from this disease.—Sir W. JOYNSON-HICKS said: This disease is not notifiable and I regret that the only figures I can give are those of cases dealt with under the Refractories Industries scheme. The new cases arising under that scheme in 1928 included 27 cases of partial and five cases of total disablement; and four deaths. In addition, there were three deaths of workmen who had previously been in receipt of compensation.

MEDICAL BATHS, TORQUAY.—A new vita-glass sun lounge at the Medical Baths, Beacon Hill, Torquay, will be opened by Sir Henry Gauvain on Feb. 20th, at 3.30 P.M.

ELLA SACHS PLOTZ FOUNDATION FOR THE ADVANCEMENT OF SCIENTIFIC INVESTIGATION.—The fifth annual report of this Foundation has just been issued. During the year 43 applications for grants were received by the Trustees, 29 of which came from other countries and 14 from the United States. The total number of grants made was 21. In the five years of its existence the Foundation has made 73 grants and investigators have been aided in the United States, Great Britain, France, Germany, Austria, Hungary, Switzerland, Italy, Sweden, Esthonia, Czecho-Slovakia, Poland, Chile, and Syria. A list of investigators and of the researches which have been aided in the current year is given. In accordance with the statement made by the trustees regarding the purposes for which the Fund would be used those researches are favoured that are directed towards the solution of problems in medicine and surgery or in branches of science bearing on medicine and surgery. As a rule preference is given to researches on a single problem or on closely allied problems. Grants may be used for the purchase of apparatus and supplies that are needed for special investigations, and for the payment of unusual expenses incident to such investigations, including technical assistance, but not for providing apparatus or materials which are ordinarily a part of laboratory equipment. Stipends for the support of investigators will be granted only under exceptional circumstances. In 1928 the largest grant given was $1000 (to each of three workers) and the smallest given was $250. No grants to British workers appear to have been made during the year. Applications for grants to be held during the year 1929–30 should be in the hands of the Executive Committee before May 15th, 1929. Applications should include statements as to the character of the proposed research, the amount of money requested, and the objects for which the money is to be expended, and should be addressed to Dr. Joseph C. Aub, Huntington Memorial Hospital, 695, Huntington-avenue, Boston, Mass.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent congregations the following degrees have been conferred:—

M.D.—A. D. Porter.
M.B. and B.Chir.—W. J. Lloyd.
B.Chir.—S. D. Isaacs and W. E. Underwood.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the undermentioned subjects:—

Surgery.—J. S. B. Bray, Cambridge and St. Bart.'s Hosp. N. N. Datta, London Hosp.; A. R. Edwards, Liverpool; and C. F. H. Quick, St. Mary's Hosp.
Medicine.—G. E. Bent, Manchester; J. S. B. Bray, Cambridge and St. Bart.'s Hosp.; and A. Weeks, St. Bart.'s Hosp.
Forensic Medicine.—J. S. B. Bray, Cambridge and St. Bart.'s Hosp.; J. Freud, Vienna and St. Bart.'s Hosp.; L. P. Gregory, Bristol; I. Lipschitzi, Liverpool; and A. Weeks, St. Bart.'s Hosp.
Midwifery.—J. Freud, Vienna and St. Bart.'s Hosp.; H. G. Edmunds, Univ. Coll. Hosp.; and D. F. Michael, St. Mary's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: G. E. Bent, J. S. B. Bray, J. Freud, and A. Weeks.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an ordinary quarterly Comitia of the College held on Jan. 31st, the President, Sir John Rose Bradford, being in the chair, the following candidates, having satisfied the Censors' Board, were elected to the Membership of the College:—

Eric Newmarch Allott, Gerald Vincent Francis Doyle, Gareth Aimers Eason, Alfred Henry Gerrard, Jessie Gordon, Lazarus Hartston, Kenneth Hoani Holdgate, Herbert Hylton Hyland, Simon Kelly, Michael Edward Lampard, Samson George Moore, Kenneth Beeson Noad, Walter Gordon Chisholm Paterson, Robert Sturtevant Pilcher, Charles Percy Pinckney, Francis Crosbie Roles, Cyril Dee Shapland, Bryan Buckley Sharp, Clive Henry Sippe, Robert Stanley Steel, Robert W. Glennan Stewart, Warrington Yorke, Janet Dorothea Ernestine Young.

Licences to practise were conferred upon 149 candidates (134 men and 15 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

H. H. Aitchison, Oxford and London; G. G. Allan, Cambridge and Univ. Coll.; Lucy E. Arthur, Royal Free; M. W. Atkinson, Middlesex; S. W. Barber and R. C. Bennett, St. Bart.'s; H. Bernstein, Cape and Univ. Coll.; G. H. Bradshaw, Cambridge and St. Bart.'s; Rochelle Churin, Royal Free; F. Clifton, Cambridge and St. Thomas's; G. C. Cochrane, Liverpool and London; C. E. Corrigan, Manitoba; C. F. Cosin, Guy's; Florence K. Costello, Sydney and Charing Cross; P. J. Cowin and D. F. L. Croft, St. Bart.'s; R. Cutler, Guy's; L. E. Daniel, Madras and St. Thomas's; C. J. M. Dawkins, Cambridge and Middlesex; E. M. Dimock, Cambridge and Univ. Coll.; J. Donovan, Leeds; H. A. Eason, London; A. M. Easton, St. Thomas's; J. A. Eddy, Oxford and Middlesex; M. A. A. El Gammal, Cairo; A. C. Elkin, Univ. Coll.; G. W. Etches, Leeds and London; T. Evans, Bristol; T. C. J. Evans, Birmingham and St. Mary's; A. D. Everett, St. Bart.'s; T. D. Finey, Adelaide and London; W. R. Forrester-Wood, Cambridge and St. Bart.'s; C. H. Forsyth, London; E. Foster, Cardiff and St. Mary's; R. H. Francis, Cambridge and St. Bart.'s; S. L. Gargye, Indore and Manchester; W. S. Ghai, Punjab and Charing Cross; J. M. Gibson, Oxford and St. Thomas's; P. J. E. Godard, Lausanne and Paris; M. W. Gonin, I. Gordon, and J. T. C. Gray, St. Bart.'s; D. R. Griffith, St. Thomas's; C. C. Griffiths, Liverpool; A. J. Groenewald, Cape and Guy's; Gwendoline E. Grove, Cambridge and St. Mary's; R. G. Gwynne, Adelaide and London; M. K. Gyi, Guy's; R. W. Haines, Univ. Coll.; A. S. Hall, Cambridge and St. George's; H. S. Hamlin, St. Thomas's; J. M. Harker, London; H. M. Harris, Oxford and London; G. F. Harrison, St. Thomas's; F. F. Hellier, Cambridge and Leeds; R. T. Hicks, Univ. Coll.; Louisa S. Hobbs, Charing Cross; R. C. Holderness, Leeds; F. W. Holdsworth, Cambridge and St. George's; G. J. Hollis, South Africa and Guy's; A. S. Hoseason, St. George's; R. I. Hyder, London; C. G. Jobbins, Cambridge and St. Thomas's; Margaret L. Jones, Univ. Coll.; O. T. Jones, Cardiff and St. Bart.'s; H. W. Jordan, Univ. Coll.; S. E. Knowles, Guy's; L. W. A. Lankester and J. F. V. Lart, Cambridge and St. Thomas's; Cesia Leben, Univ. Coll.; Florence M. Lessing, Univ. Coll. and Charing Cross; A. Levy, St. Thomas's; K. Lindberg, Paris and Middlesex; A. G. Lloyd, Durham; R. M. B. Lowis, St. Thomas's; Dorothy M. Lufkin, Univ. Coll.; R. Machray, Westminster; J. K. Marshall, Oxford and Guy's; A. Mathews, London; S. N. Mathur, Lucknow and London; R. A. Maynard, Cambridge and St. Thomas's; K. G. Milad, St. Mary's; W. B. Millar, Middlesex; M. V. Modi, Bombay and London; G. Morgan, St. Mary's; G. H. Morley, Middlesex; J. E. Myers, Adelaide and London; T. H. Negus, St. Thomas's; D. A. Nicoll, King's Coll.; G. S. Nightingale, London; W. G. Oakley, Cambridge and St. Bart.'s; R. I. O'Farrell, Sheffield; T. L. Owen, Leeds; L. G. M. Page, St. Bart.'s A. J. Parer, Sydney and King's Coll.; A. F. Parker, London; A. R. D. Pattison, Durham; I. Preiskel, St. Bart.'s; R. Purvis, St. Thomas's; S. M. Rahman, Calcutta and Middlesex; A. S. Rajasingham, Ceylon and Middlesex; T. G. Reah, Cambridge and London; Dorothy K. Reynolds, King's Coll.; A. C. Riley, St. Bart.'s; G. L. Robinson, Cambridge and London; V. C. Robinson, Cambridge and St. Bart.'s; T. S. Rodgers, Westminster; E. B. Rogers, Guy's; B. Rothery, Cambridge and St. George's; A. S. D. Russell, St. Thomas's; B. W. Rycroft, St. Andrew's; N. Sachnovics, Berlin and Guy's; H. R. D. Schofield and T. L. Scott, St. Mary's; Mary Scouloudi, Univ. Coll.; D. A. Seaman, Birmingham; J. E. Semple, Cambridge and St. Thomas's; G. M. A. Shaikh, Bombay and London; Mary E. Sharp, Univ. Coll.; J. D. Simpson and A. D. Skyrme, Cambridge and London; C. E. Soodeen, Middlesex; A. Southgate, Charing Cross; B. Stanley, Univ. Coll.; H. Stark, St. Bart.'s; E. T. W. Starkie, Cambridge and St. Mary's; G. A. Stevenson, Birmingham; E. C. Sugden and H. Taylor, Cambridge and St. Bart.'s; I. Taylor, King's Coll.; V. C. Thompson, Cardiff and St. Bart.'s; S. A. Underwood, St. Mary's; Bertha D. Upton-Jones, Royal Free; V. C. Verbi, King's Coll.; Frances J. Vinter, Royal Free; W. E. Wainman, Leeds; C. M. E. Warner, Bengal and King's Coll.; R. P. White and J. S. Whiting, Cambridge and St. Bart.'s; Florence Whitrow, Manchester; A. G. Williams, Cardiff and St. Bart.'s; A. W. Williams, Cambridge and Westminster; J. D. Williams, Cardiff; Beatrice M. Willmott, Cambridge and Birmingham; G. M. Willoughby, Middlesex; W. R. Winterton, Cambridge and Middlesex; F. G. Wood-Smith, Cambridge and St. Bart.'s; R. G. Zaglama, Assiut and Manchester; E. Zimbler, Dorpat and Middlesex.

The undermentioned diplomas were also conferred conjointly with the Royal College of Surgeons, to the following candidates:—

Diploma in Public Health.—G. E. Addison, N. T. Advani, C. L. Ahluwalia, J. S. Allan, A. N. Chopra, Marguerite E. Cliff, W. Conroy, K. St. V. Edwards, E. Egan, J. Egan, V. Feldman, J. Ferguson, M. T. Fernando, Barbara Finch, A. N. Ghei, Winefride M. Gibson, N. G. Hill, Katherine M. Hirst, D. P. Holmes, Amelia M. Ison, C. W. W. Jeremiah, Ellen F. Kelleher, W. H. Kelleher, L. D. Khatri, E. T. Lloyd, W. S. Martin, M. V. Merchant, P. L. Nirula, Mary O'Leary, Helen E. D. E. Ornstein, W. G. Patterson, R. F. Pinson, F. W. G. Smith, R. B. Subramanyam, R. W. C. Thambiah, D. J. Valentine, and E. M. Wright.
Diploma in Psychological Medicine.—R. W. Armstrong, Eileen A. Chennell, A. Craig, H. Hinchco, Phyllis M. Horton, D. L. McCullough, D. Menzies, J. E. Nicole, Muriel L. M. Northcote, Eveleen J. O'Brien, J. C. Ramsay, and C. E. Roachsmith.
Diploma in Laryngology and Otology.—M. I. Ashmawi, A. Blagoff, N. M. Eadie, M. Husnain, N. H. Meacle, H. V. O'Shea, H. M. Petty, S. Roy, E. C. Tamplin, and W. L. Thomas.

Dr. C. H. J. Lockyer was elected to the Council in the place of Sir Hugh K. Anderson (deceased), Dr. Gordon Holmes was elected examiner in psychological medicine, and Dr. W. J. Fenton examiner in medicine.—The award of the Swiney Prize for 1929 to Dr. Sidney Smith was announced.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—The next quarterly meeting of this Association will be held on Feb. 14th at the British Medical Association House, Tavistock-square, London, W.C., under the presidency of Prof. J. Shaw Bolton, when the discussion on General Paralysis, adjourned from the November meeting, will be resumed.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—A conversazione will be held at the Society's house, 17, Bloomsbury-square, London, W.C., on Tuesday, Feb. 12th, from 7.30 P.M. to 10 P.M., when the whole premises will be open to visitors, and exhibits will be shown in the museums and laboratories.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting will be held at the Miller General Hospital, Greenwich, London, S.E., to-day, Feb. 8th, at 8.45 P.M., when Mr. H. P. Winsbury White will read a paper on Chronic Infection of the Urinary Tract, its Causes and Treatment, with illustrations.

MANCHESTER AND DISTRICT RADIUM INSTITUTE.—The executive committee of this Institute have decided, subject to careful safeguards, to let out radium on hire to hospitals and to practitioners. Up to the present this has not been done in Manchester, although it is the custom at the London Radium Institute and the Belgian Institution in Brussels. The conditions of hire have yet to be formulated. The committee have also decided to make a further purchase of radium for this purpose, money having been received from the trustees of the late Mr. John Barlow. Dr. G. E. Birkett, who has been radiologist to the Institute during the past six years, has been appointed honorary consulting radiologist. It has been decided to appoint a second assistant radiologist, so that in future there will be three experts constantly working in the service of the Institute.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school is appealing for £150,000 in order to free itself from continual financial embarrassment. The appeal embraces a scheme to commemorate Alexander Mackay, of Uganda, by endowing research fellowships in the school. Miss Caton, daughter of the late Prof. Richard Caton, M.D., has given £2000 to be devoted to an object which can be associated with her father's name. This sum is to be earmarked towards the endowment of a Caton Research Fellow in Biochemistry.

THE NEW FREEMASONS' HOSPITAL.—It is estimated that the total cost of providing the new Freemasons' Hospital at Ravenscourt Park, Hammersmith, will be a quarter of a million. The hospital has outgrown its present quarters in the Fulham-road, the number of patients last year, 686, having been the largest on record. Of these, 244 came from the provinces and overseas. The new site, which practically adjoins Ravenscourt Park, is 3½ acres in extent, and there are to be from 120 to 130 beds, a very large increase upon the present number, with capacity for easy extension.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 12th.—8.30 P.M., PSYCHIATRY and NEUROLOGY, Special Discussion on Prognosis and Treatment of General Paralysis of the Insane. Openers: Dr. W. H. B. Stoddart (Psychiatry), Sir James Purves-Stewart (Neurology). Other speakers: Dr. J. Brander, Dr. G. de M. Rudolf, Major F. H. Stewart, I.M.S., Dr. Thomas Tennent, Surgeon Rear-Admiral E. T. Meagher, R.N., Dr. R. M. Stewart, and others. THERAPEUTICS: There will be no Meeting of this Section in February.

WEDNESDAY.—5.30 P.M., SURGERY: SUBSECTION OF PROCTOLOGY. Short Papers: Mr. W. B. Gabriel: Case of Carcinoma of the Rectum Complicated by Enlarged Prostate. Dr. P. H. Manson-Bahr: Pathology of Bilharzia and Amœbic Dysentery of Colon and Rectum. Mr. R. Maingot: Three Cases of Acute Intestinal Obstruction Due to Fæcal Impaction. Mr. A. Lawrence Abel: Three Cases of Multiple Cancers of Rectum and Colon.

THURSDAY.—5 P.M., BALNEOLOGY. (Exhibition of photographs at 4 P.M.) Discussion on Osteo-arthritis. Opening Papers will be read by: Dr. R. G. Gordon (Bath). Dr. J. A. Thomson (Harrogate): Osteo-arthritis Radiographically Considered. Dr. Tom Hare and Dr. Henry Cohen: The Chemical Estimation of Synovial Fluid and Blood Serum of Horses Affected with Chronic Arthritis. 8.30 P.M., PSYCHIATRY and NEUROLOGY. Special Discussion on Prognosis and Treatment of General Paralysis of the Insane, continued from Tuesday.

FRIDAY.—8 P.M., OBSTETRICS. Paper: Prof. J. Heyman (Stockholm): The Uses of Radium in the Treatment of Malignant Diseases of the Uterus and Ovaries. Mr. Victor Bonney and Dr. J. D. Malcolm will also speak. 8 P.M., ELECTRO-THERAPEUTICS. Discussion on Chronic Rheumatism of Joints and Muscles; Diagnosis and Treatment.

ROYAL INSTITUTION, Albemarle-street, W.

THURSDAY, Feb. 14th.—5.15 P.M., Sir William Bragg: The Early History of X rays.

FRIDAY.—9 P.M., Mr. E. K. Rideal, D.Sc.: Chemi-Luminescence.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C. (Arris and Gale Lectures.)

MONDAY, Feb. 11th, WEDNESDAY, and FRIDAY.—5 P.M., Prof. H. A. Harris: Bone Growths in Health and Disease.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 11th, to SATURDAY, Feb. 16th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., at 5 P.M., Lecture, Mr. Andrew Wylie: The Difficulties Experienced in the Diagnosis of Laryngeal Diseases. Thurs., at 4.30 P.M., Lecture, Dr. Gerald Slot: Calcium Therapy.—PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. Mon., at 2.30 P.M., Clinical Demonstration, Mr. Aubrey Goodwin (Gynæcology), Out-patient Department.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Tues., at 6 P.M., Demonstration, Dr. J. E. M. Wigley (Dermatology).—WELLCOME MUSEUM OF MEDICAL SCIENCE, 33, Gordon-street, W.C. Wed., at 4 P.M., Demonstration, Dr. S. H. Daukes: A Consideration of Various Types of Ulceration Met with in the Stomach and Intestines. The above are free.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Special Course in Gynæcology. Some mornings and afternoons.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Special Course. Afternoons and evenings. Lectures twice weekly. Duration four weeks. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Feb. 11th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Feb. 15th.—4 P.M., The Significance of Aural Pain

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital 49, Leicester-square, W.C.

THURSDAY, Feb. 14th.—5 P.M., Dr. J. E. M. Wigley: Lupus Erythematosus.

UNIVERSITY COLLEGE, London.

TUESDAY, Feb. 12th.—5.30 P.M., Mr. G. M. Morant, D.Sc.: The Rhodesian Man and his Relation to Other Types of Man.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street W.C.

THURSDAY, Feb. 14th.—4 P.M., Dr. Thursfield: The Prognosis of Nephritis.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Feb. 12th.—2.15 P.M., Dr. B. E. Schlesinger: Infant Feeding. 3.15 P.M., Mr. E. Wolff: Ocular Pain

NATIONAL COUNCIL FOR MENTAL HYGIENE.

WEDNESDAY, Feb. 13th.—5 P.M. (at the Medical Society of London, Chandos-street, W.), Dr. Helen Boyle: Dangerous Ages: Middle Age.

LEEDS POST-GRADUATE COURSE ON CANCER.

WEDNESDAY, Feb. 13th.—3.30 P.M. (in the Leeds Medical School), Dr. A. Leitch: Recent Researches in Cancer

ST. MARY'S HOSPITALS POST-GRADUATE LECTURE Manchester.

FRIDAY, Feb. 15th.—4.30 P.M. (at the Whitworth-street West Branch), Dr. Ward: Cough, in Infancy and Childhood.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS

FRIDAY, Feb. 15th.—3.30 P.M., Mr. Yates: Surgical Cases

Appointments.

FERGUSON, F. R., M.D. Manch., D.P.H., has been appointed Registrar to the National Hospital for Nervous Diseases, Queen-square, W.C.

GARTON, W., M.R.C.S., D.M.R. & E. Camb., Honorary Radiologist to the Kent and Canterbury Hospital.

SEVERN, A. G. M., M.D. Brux., L.R.C.P. Lond., M.R.C.S., D.P.H., Medical Officer of Health for Pontypridd.

TROUP, JAMES, M.B., Ch.B. Manch., F.R.C.S. Edin., Honorary Assistant Surgeon to the Royal Hampshire County Hospital, Winchester.

Certifying Surgeons under the Factory and Workshop Acts ERSKINE, W. A., M.B., Ch.B. Edin. (Parbold, Lancaster) GANE, E. P. S., M.D. Durh. (Llansawel, Carmarthen) and MCCREA, R. A., M.B., B.Ch. (Chesterfield, Derby).

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Bootle Borough Hospital, Derby-road.—Sen. M.O. Also Two Jun. M.O.s. At rate of £150 and £125 respectively.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £120.

Brighton, French Convalescent Home, de Courcel-road, Kemp Town.—Hon. Visiting Physician.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £100.

Cancer Hospital, Fulham-road.—Director of Electrical and Radio-Therapeutic Dept.

Cardiff, City Lodge Institution.—Third Asst. Res. M.O. At rate of £100.

Cardiff, University College of South Wales and Monmouthshire.—Lecturer and Demonstrator in Anatomy. £400.

Carlisle, Cumberland Infirmary.—H.P. Also Two H.S.'s. Each at rate of £155.

Charing Cross Hospital, W.C.—Hon. Clin. Asst. in X Ray Dept.

Chesterfield and North Derbyshire Royal Hospital.—Cas. H.S. At rate of £100.

Derby, Derbyshire Royal Infirmary.—Asst. H.S. and Cas. O. At rate of £150.

Derby, Royal Derby and Derbyshire Nursing and Sanitary Association.—Hon. Obstetric Physician to the Nightingale Nursing Home.

Dreadnought Hospital, Greenwich.—Phys. to Out-patients.

East Ham Memorial Hospital, Shrewsbury-road, E.—Hon. Asst. Physician.

Glasgow, Hawkhead Asylum, Crookston.—Jun. Asst. M.O. £27

Hospital for Sick Children, Gt. Ormond-street, W.C.—Cas. O. £400. Also Asthma Research Scholar. £300.
Ipswich County Borough.—Asst. M.O.H., &c. £600.
Jersey Mental Hospital.—Med. Supt. £650.
Liverpool, David Lewis Northern Hospital.—H.S. for Orthopædic, &c. At rate of £100.
L.C.C. Mental Hospital Service.—Eighth Asst. M.O. £300.
Lucknow University.—Professorship of Medicine and Physician to King George's Hospital. Rs.1200–50–1400 p.m.
Manchester, Ancoats Hospital.—H.P. At rate of £100. Also H.S. Orthopædic. £100
Manchester and Salford Hospital for Skin Diseases.—H.S. £100.
Manchester Hospital for Consumption, &c.—Hon. Asst. Phys.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Refraction Clerk to the Ophthalmic Dept. £150.
Newport, Mon., County Borough Mental Hospital.—Asst. M.O. £300.
Perth, James Murray's Royal Asylum.—Asst. Physician. £300.
Queen's Hospital for Children, Hackney-road, E.—Anæsthetist. £25. Also Res. M.O. £200.
Rampton State Institution for Mental Defectives, near Retford.—M.O. £536 10s.
Royal Free Hospital, Gray's Inn-road, W.C.—Eastman Dental Clinic Director.
Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.
Ryde, Royal Isle of Wight County Hospital.—Vacancy on Hon. Medical Staff.
St. John's Hospital, Lewisham, S.E.—Hon. position in Psychological Medicine.
St. Paul's Hospital, Endell-street, W.C.—Hon. Cardiologist.
Smethwick County Borough.—Sen. Asst. M.O.H. £550.
Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £175, H.P. £130, Jun. H.S. At rate of £130. Also Cas. O. At rate of £120.
Sudan Government.—Medical Officer. £E.852.
Surrey Administrative County of.—County M.O.H. £1800.
Swansea County Borough Infectious Diseases Hospital.—Res. M.O. £350.
Swansea Hospital.—H.S. £150.
Tunbridge Wells and Counties General Hospital.—H.S. £160.
Warwick County Mental Hospital, Hatton.—Jun. Asst. M.O. £350.
Watford, Herts, Peace Memorial Hospital.—Res. M.O. At rate of £150.
West Bromwich and District General Hospital.—H.S., H.P. Also Cas. H.S. Each at rate of £200.
West London Hospital, Hammersmith-road, W.—Hon. Obstetric Registrar.
Willesden General Hospital, Harlesden-road, N.W.—Hon. Ophthalmic Surgeon.
Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—Hon. Sen. Dental Surg., Hon. Dental Surg. Also Asst. Phys. to the Radiological Dept. £50.
York Dispensary.—Res. M.O. £150.
The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Hollingbourne (Kent).

Births, Marriages, and Deaths.

BIRTHS.

BEWLEY.—On Feb. 2nd, at Courtfield-road, South Kensington, the wife of Dr. Maurice Bewley, of a daughter.
HEFFERNAN.—On Jan. 26th, the wife of Major P. Heffernan, I.M.S. (retired), of a son.
MARSHALL.—On Jan. 30th, at a nursing home, Sheffield, the wife of Dr. G. G. Marshall, of a son.

DEATHS.

CLARK.—On Jan. 26th, George Clark, M.B., C.M., of Stockwell Park-road, S.W.
EDDISON.—On Jan. 27th, at Woodcroft, Cuckfield, Sussex, John Edwin Eddison, M.D., aged 86.
HAYNES.—On Jan. 28th, at Cathcart-road, South Kensington, Dr. James Robert Haynes, in his 86th year.
ILES.—On Jan. 31st, at Vivary Cottage, Taunton, Alfred Robert Iles, M.R.C.S. Eng., L.R.C.P. Lond., in his 77th year.
OGSTON.—On Feb. 1st, at Union-street, Aberdeen, Sir Alexander Ogston, K.C.V.O., M.D., LL.D.
OWEN.—On Jan. 31st, at 13, Rodney-street, Liverpool, of acute pneumonia, John Owen, M.D., F.R.C.P., aged 58, hon. physician, Liverpool Royal Infirmary.
SCORESBY-JACKSON.—On Jan. 30th, at 31, Thornsett-road, Anerley, S.E.20, Thomas Scoresby-Jackson, M.D., aged 79 years. Internment Monday, February 4th, in Elmers End Cemetery.
SHARP.—On Jan. 26th, at Charnwood House, Derby, John A. Sharp, M.R.C.S., L.R.C.P., consulting surgeon to the Derbyshire Royal Infirmary, in his 82nd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. II., 1928.

THE Index and Title-page to Vol. II., 1928, which was completed with the issue of Dec. 29th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

NIGHT VISION OF AVIATORS.

How much can a man see in the darkness of the night, and how long does it take him to become fully accommodated to the darkness? An answer to these questions is given by Surg. Lieut.-Col. P. J. E. Beyne and Surg.-Commander G. Worms, from the French Medico-Physiological Laboratory of Military Aviation, in the *Archives de Médecine Militaire* for last September (p. 231). They measured the vision of three aviators on a clear dark night in September, decided later, in a dark chamber, on the artificial illumination required to give the same vision—this they state as 0·0015 lux—and after many experiments declare the acuity of night vision to be 6/100 to 9/100 of what is considered normal by day. They found, too, that it lessens with age over 30, and that it does not reach its maximum until after 20–35 minutes in darkness. These figures are for Europeans; two natives of Tonkin both reached 10/100 in 25 minutes, an acuity greater than in any European examined. Night vision is, the investigators say, so important to aviators employed as night fliers or night bombers that they must be specially selected, attention being given both to the keenness of their night vision and the rapidity of its attainment. They further recommend that in night-flying areoplanes the dials on the dashboard shall only be illuminated with red-purple lamps, the less to disturb the pilot's vision as he flies.

A MEDICAL RECLUSE.

A VERDICT of "death from natural causes" was returned at an inquest in Leeds on Feb. 1st on A. Clarence Foster, M.R.C.S., of Leeds, aged 84, son of a well-known Leeds doctor. He lived for many years with his elder brother Philip, an M.D. of St. Andrews, who died in August, 1927, and who left over £40,000. The two brothers occupied a house for over 70 years in Park-place, now the centre of a business area. Dr. Clarence Foster had not practised for many years and occupied the back rooms in the house, living the life of a recluse in a most frugal way, wearing tattered clothes and broken shoes. He was attended only by an old woman who occasionally went to clean his rooms, and who on getting no response to her call, informed the police. The doctor was found lying in a passage. He was taken to the infirmary and died a few hours later. He qualified M.R.C.S. Eng. in 1868 and was the author of "A Brief Historical Account of the Hôtel-Dieu, Paris, 1875," "Memorial Sonnets of Italy," and "Biographical Sketch of William Dunbar, Laureate to James IV.," 1891. Philip Foster published in THE LANCET, 1872, an account of a case of Cæsarean operation with recovery.

A BED-MAKING DEVICE FOR BEDRID PATIENTS.

THE difficulties of making the beds of helpless patients are not to be minimised. In a large hospital, with excellent equipment and a highly skilled nursing staff, these difficulties are not very apparent, but bed-making by attendants of only moderate skill may be a daily trial attended by much unnecessary discomfort and suffering. A device, known by the rather cumbersome title, "A Combined Bed Re-making and Transport Stretcher," has been invented and described by Dr. S. Orell (Acta Chir. Scand., 1928, lxiv., 24), and he suggests that it should be put into routine hospital use for bedridden patients. This may be unnecessary, but where skilled attention is not available the device might well be adopted. A frame, shaped so that it can be pushed over the bed, is surmounted by a stretcher which rotates in a longitudinal axis. The patient is rolled upon his side by a nurse, the frame is pushed over the bed, and the stretcher is rotated until it lies along his back. The patient is allowed to fall back on the stretcher, which is then rotated to the horizontal position, and the whole frame is wheeled away while the bed is re-made. The patient is deposited in bed again by reversing the process. There is no lifting, but only rolling or turning, and this makes the apparatus of great value for moving very heavy patients.

NEW PREPARATIONS.

We have received from Messrs. Cranbux, Ltd., of Westwick-street, Norwich, an assortment of flasks of *Odol* and tubes of *Odol paste*, for which the manufacturers claim merits as an antiseptic oral preparation. The preparation is so popular that no words are necessary to describe its properties as a pleasant cleanser and deodoriser in which certain antiseptic powers can be identified.

Syrup Pertussis (*Gabail*) is a product for which the Anglo-French Drug Company, Ltd., 238A, Gray's Inn-road, London, W.C., are the agents, and the claim is made that it is particularly effective in treating the paroxysms of whooping-cough. The formula is ext. valerian deodorised 2·4 g., amm. valerianate 2·4 g., strontium bromide 2·0 g., chloral hydrate 3·0 g., ext. droseræ liq. 2·0 g., syr. rubus idœus 60 c.cm., aq. destillata ad 125 c.cm., and the dosage is as follows: From 6 months to 1 year, two teaspoonfuls of the syrup mixed with a tablespoonful of sweetened water, a teaspoonful of which mixture is given every three hours; from 2 to 4 years, two teaspoonfuls of plain syrup in the morning, one at midday and one in the evening with meals; and from 4 to 12 years, one tablespoonful in the morning, midday, and evening, and an additional tablespoonful two hours after going to bed. The preparation is only a remedy for, or alleviation of, the coughing fits and vomiting, as is indicated by the presence in it of sundew and valerian, while strontium has a reputation for value in vomiting of nervous origin. The manufacturers do not claim that it is in any sense a cure for whooping-cough.

Benzyl Cinnamic Ester (*Dr. Jacobson's Solution*).—In THE LANCET of May 5th, 1928, is a note on the use of Benzyl Cinnamic Ester in Tuberculosis by Dr. H. Gainsborough, who describes the use by Dr. J. Jacobson of balsam of Peru as a remedy for certain forms of tuberculosis, especially of the skin. Jacobson, in 1919, suggested an analogy between tuberculosis and the disease due to pathogenic fungi, and the employment of the balsam is justified on account of its antiparasitic properties. French experience, according to Gainsborough, has given encouraging results in the treatment of pulmonary tuberculosis by benzyl cinnamic ester, but his observations were made mainly upon cases of external manifestations, although, in addition to reporting encouraging results in various cases of discharging sinus and lupus, he describes the relief also of typical cases of pulmonary, laryngeal, and renal tuberculosis with cystitis. The results which Jacobson obtained in treatment of tuberculosis of the skin at the Hôpital St. Louis have been confirmed by J. Darier, E. Jeanselme, M. Mitchitch, and other observers. The manufacturers and agents in Great Britain of Dr. Jacobson's solution are Messrs. Boots Pure Drug Company, Nottingham. The solution is supplied in 1 c.cm. vials, with the following description of Jacobson's method of administration in external and general tuberculosis:—

"(*a*) Cases of external tuberculosis unaccompanied by pulmonary or bucco-laryngeal tuberculosis are given an injection of 1 c.cm. of the solution.

"(*b*) Cases of external tuberculosis complicated by pulmonary or bucco-laryngeal tuberculosis are given the same doses as are recommended in the treatment of pulmonary tuberculosis.

"(*c*) In pulmonary and bucco-laryngeal tuberculosis the dose is 0·25 c.cm. of the solution. If, however, the general condition of the patient is good, 0·5 c.cm. can be administered. For children between eight and twelve years of age, half the adult dose is given."

The treatment of varicose veins by the injection of sclerosing solutions should be facilitated by the use of "*Hypoloid*" *Quinine and Urethane*, which has recently been issued by Messrs. Burroughs, Wellcome and Co. This solution consists of quinine hydrochloride 0·26 g. and urethane 0·13 g. in 2 c.cm. of sterile distilled water, issued in hermetically sealed glass containers ready for immediate use. Special literature on the successful use of this solution is supplied for the guidance of medical practitioners and may be obtained on request. The containers are issued in boxes of five.

Terpoflor Nasal Capsules.—Messrs. Wilcox, Jozeau and Co., 15, Great St. Andrew-street, London, W.C., are the agents of this preparation, which is intended for the disinfection of the respiratory passages. The formula is given as follows: cedrene 0·010, pinene 0·010, anethol 0·012, terpineol 0·004, camphoric aldehyde 0·010, cineol 0·008, methyl ortho-amido-benzoate 0·007, linalyl acetate 0·004, sesquiterpenes 0·035, extra paraffin oil 0·900. It is put up in the form of gelatin capsules, shaped like an ampoule. In application the end of a capsule is cut off and the contents squirted into the nostrils, the head being thrown well back. This may be done several times a day but only on the recommendation of a doctor, as the sensitiveness of the mucous membrane of the patient as well as other idiosyncrasies may vary. The preparation is indicated in affections of the upper respiratory tract, and is claimed rapidly to relieve congestion and the disagreeable feeling of a stopped-up nose in cases of cold in the head.

Dimol Pulverette and Dimol Mouth Wash (Dimol Laboratories, Ltd., 40, Ludgate-hill, London, E.C. (Agents: Sangers, 258, Euston-road).—These are two new preparations of Dimol, a well-known intestinal disinfectant which has already been referred to in these columns. Its chemical constitution is $C_6H_2(CH_3)_2(OCH_3)OH$, and it is free from toxicity. The Dimol Pulverette is prepared according to the formula dimethylomethoxyphenol gr. 1, acid arsen. gr. 1/180, ext. nuc. vom. gr. 1/16, and will be known as T; further, to safeguard against confusion with Pulverettes A (white) and B (yellow) the new pulverette is coloured pink. Its use is that of a nerve and general tonic combined with a non-toxic intestinal bactericide. The Pulverette T is put up in glass bottles and the dose is 2 or 3 three times a day, to be taken with a draught of water immediately after meals. The mouth wash, which is guaranteed to have the Rideal-Walker coefficient equal to 20 per cent. pure carbolic acid, is put up in bottles with a sprinkler top and cap and a few drops according to taste are shaken into half a tumbler of water. The strength may be increased when used as a gargle for relaxed throat or infected tonsils.

(*Continued from previous column.*)

EMPLOYMENT FOR THE TUBERCULOUS.

THE experience of the New York Tuberculosis and Health Association in finding work for convalescent cases is now available in book form.[1] This original investigation was supported partly out of the funds of the Association and partly by a grant from the Laura Spelman Rockefeller Memorial. It was found inexpedient to list trades and occupations suitable for the tuberculous. Rather it is advantageous to make a list of the conditions that must be avoided as well as those which are favourable in any occupation: "There are no industries in which *all* jobs are suitable for the tuberculous, and on the other hand, there are only a few industries which have *no* jobs suitable for the tuberculous."

ROCKEFELLER FOUNDATIONS.

THE Laura Spelman Rockefeller Memorial, which was founded by Mr. Rockefeller in 1918 as a memorial to his wife, has recently been consolidated with the Rockefeller Foundation which title is retained for the new joint body. Dr. Vincent, president of the original Rockefeller Foundation, retains that title in the new organisation. The two foundations, whose joint assets now total over $264,000,000, will continue to function, but it is hoped with greater efficiency under the united administration. The General Education Board continues as a separate body.

THE KING'S ILLNESS.

OFFICIAL BULLETIN.

(*Continued from p. 270.*)

THE following official bulletin has been issued:—

MONDAY, FEB. 4TH.

The King continues to gain strength slowly, and was able to sit up on Saturday and Sunday for a short time. The question of ray therapy has been further considered. The period of the administration of ultra-violet rays has terminated, and it will now be possible to supplement this treatment by the addition of luminous rays. (Signed by Sir Stanley Hewett, Dr. Frank Howitt, Dr. Robert Stanton Woods, Sir Hugh Rigby, and Lord Dawson of Penn.)

Practitioner.—There seems to be no safe method of permanently curing superfluous hairs other than electrolysis in the hands of an expert, who need not necessarily be a medical person.

Erratum.—The dose of pyramidon given by Prof. H. Beyer (Berlin) for fever associated with nasal catarrh (THE LANCET, Jan. 26th, p. 198) should have been stated as 0·1 gramme, equivalent to grains 1·5.

[1] Employment of the Tuberculous, by Alice Campbell Klein and Grant Thorburn, M.D. National Tuberculosis Association, 370, Seventh-avenue, New York City. Price 50 cents.

Some Thoughts ON THE NATURE OF CANCER.

ead at a Meeting of the American College of Surgeons held at Boston, Mass., on Oct. 11th, 1928,

By Sir CHARLES A. BALLANCE, K.C.M.G., C.B., M.V.O., M.S Lond.,

CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

THE International Conference on Cancer, which as held last July in London, evoked great interest. ientists of all nations joined in its deliberations. ie goal of effort was the discovery of the intimate ture of the disease and of the means for the pre- ntion and cure of its lethal incidence on the human ce.

When Homer told the story of Troy he did not ite prose or even history; he everywhere infused to it an incomparable ardour—he made an epic. a epic is a theme of action treated in heroic propor- ns and style. In our profession the life enthusiasms d moral qualities of such men as Pasteur and Lister esent to our minds epics of incomparable ardour. ieir struggles were great, the issues were great, the en were great. It appears to me that the hopeful le of our labours is that some of our colleagues are proaching the subject of the cause of cancer in the ic spirit. "The most important events of history e to the novelist what gigantic mountains are to the aveller. He surveys them, he skirts their base, he lutes them as he passes, but he does not climb em." In the same way I propose to survey, skirt, d salute some of the great landmarks in the history research into the nature of cancer.

Debates at the Conference.

The chief papers and debates at the London ngress dealt with the early diagnosis and the lative value of surgery and radiation in the treatment carcinoma of the stomach, mamma, uterus, mouth, d rectum, and of sarcoma of bone. There was also short statement by Dr. T. Lumsden concerning mour immunity and vaccine treatment, but the bate which interested me most was that on the iology of cancer. The use of lead as a remedy did t obtain general acceptance. There was a general eling that the rule persists that operation is sential in the treatment of cancer, but that opera- n combined with radium was, in certain cases e.g., carcinoma of the mamma—of increasing lue. For sarcoma of bone, in which amputation does it delay the fatal issue, some hopeful results were ported following the use of radium and toxins or dium alone. The biological effects of radium and rays were discussed by experts.

When I was a house surgeon it was generally thought at an attack of erysipelas after an operation for rcinoma mammæ had some effect in preventing the currence of the disease. I was in Berlin in 1884. hleisen was assistant to von Bergmann and he was fecting cases of carcinoma mammæ with the organism erysipelas. The students nicknamed Fehleisen erysipelas coccus." When the attack of erysipelas as severe the tumour might slough out. A death curred and the treatment was stopped. Fehleisen as a forerunner of Dr. William B. Coley. This gives e the opportunity of paying a humble tribute to the ansparent honesty and diligence of my friend Coley ring a long period of years in his attack on the oblem of cancer treatment. I have no doubt yself of the beneficial influence of the toxins in rtain cases of cancer.

Paracelsus held that Nature was sufficient for the re of most diseases; Art had only to interfere when e internal physician was tired and incapable. Then me remedy had to be introduced which should be antagonistic, not to the disease in a physical sense, but to the spiritual seed of the disease. I look forward to the time when our terribly mutilating operations for the cure of cancer, which must be performed at present, will be replaced by a vaccine or some such remedy which will be antagonistic to the spiritual seed of the disease. Dr. Lumsden spoke of tumour immunity and vaccine treatment. He said that antibodies could be produced which had a specific affinity for cancer cells; they attacked and killed the cancer cells without damaging normal tissue cells. After using vaccine the immunity was much higher than otherwise. He suggested that those who were treating tumours with radium should not be in a great hurry to get rid of the local growth by sloughing, because this would prevent the increase of immunity.

It has long been known that most tumours in the commonly used experimental animals retrogress after a time, and that such animals are immune and cannot be further successfully grafted. Many years ago at the Buffalo Cancer Laboratory I saw mice which had in this manner become immune. This is not at all comparable to the retrogression of spontaneous tumours. Hence the same observation is rare in man. Many surgeons of much experience have observed the slow disappearance of a malignant tumour.

No one of us doubts the importance of the early diagnosis of malignant disease. But when a cancer gives a sign or a symptom it is not in the early stage of growth. I have no faith in what has been termed the pre-cancerous stage; to me either a patient is suffering from malignant disease or he is not. I am all in favour of the intensive education of the family doctor concerning all newly discovered facts which may aid him in early diagnosis; but I am not in favour of lecturing to men and women of the lay public on a subject which they cannot in any measure understand, and which is with them ever associated with fear and dread. Fear and dread depress the resistance of the body cells and like injury may be the partial cause of the disease.

The debate in London on the early diagnosis of cancer of the stomach and on the value of excision of simple ulcer of the stomach as a preventive measure was of much interest. I would only add this: none of us is possessed of a knowledge which can allow him to state—this simple ulcer will become malignant. The prophet is a bad guide in surgery. Furthermore, I am convinced of the immense value, in selected cases of simple ulcer of the stomach, of a posterior no-loop gastro-enterostomy, the operation which we owe to your great surgeon, William J. Mayo.

External Agent as the Cause of Cancer.

In 1884 I joined the first class in bacteriology ever formed in the ancient University of Leipzig. The teacher's name was Becker, who was Koch's first assistant. The class was held daily for six weeks and was a great success. Becker insisted that Koch's four postulates must be fulfilled before any living organism could be held to be the cause of the disease. This is as true to-day as then. My family had been decimated by malignant disease, and as a student I had made up my mind, when opportunity offered, to work at its intimate pathology. When I returned to England I met the late Prof. S. G. Shattock, who was a microscopist, and we started together on the great adventure. Sir John Simon and Sir James Paget and other great pathologists of the mid-Victorian era had noticed the vital difference in activity of the normal and cancerous epithelial cell. Speaking generally, the cancerous epithelial cell is indistinguishable anatomically from the normal epithelial cell, but its physiological life is different. The one has a normal life, but some profound change has happened to the cancer cell. It has become endowed with an immortal life and the property of endless growth. In those early days it was suggested that some outside spermatic influence caused the change in the epithelial cell which gave to it an immortal life. Whatever takes place in our bodies has two distinct factors—the intrinsic factor, which is the constitutional or

resisting power of the cells affected, and the external injurious agent. The spermatozoon, meeting the right ovule, may create a life—a sort of other life or parabiosis. I have always inclined to the belief that an external agent is the essential cause of carcinoma; that the infected epithelium is the habitat of the external agent, and that it will live and grow in none other.

In carrying out a research on the intimate nature of any disease it is essential to have an hypothesis of the nature of the disease in order to plan a scheme of work. The only scheme of work on the intimate nature of cancer which offers a prospect of success must be based on the hypothesis that some external agent is the essential cause. If it were possible, which it is not, it would be well if all our experimental work on the intimate nature of cancer could be carried out on carcinomata, since certain types of round-cell sarcoma are not easy to distinguish microscopically from granulomata, while the microscopical appearances of the carcinomata are so definite that no mistake is likely to occur. It is quite possible, and indeed probable, that the same external agent is the cause of both sarcoma and carcinoma. In the one case it finds a habitat in the mesoblastic cell, and in the other in the epiblastic or hypoblastic cell. Sir James Paget long ago pointed out that the same insect produces different kinds of galls according to the different sites of oviposition.

The view that sarcoma and carcinoma have a common origin receives support from the tale of a case reported in 1926 in the *Annales d'Anatomie pathologique* by Lècase and Lacassagne.

In 1923 a woman was operated on for advanced carcinoma mammæ. Two weeks afterwards a student of medicine, aged 21, was told to remove by a syringe fluid collected under the scar. In doing so a sudden movement of the patient caused the needle to be driven deeply into the palm of the hand of the student, and a small amount of the fluid in the syringe also entered the palm. Two years later there was a hard swelling with pain in the palm of the hand and glands in the axilla were enlarged. A little later several small tumours appeared in the forearm and arm and amputation of the limb was performed.

The beautiful illustrations accompanying the paper show clearly that the mammary tumour was a spheroidal-celled carcinoma, while the tumours which grew in the student's hand and arm were spindle-celled sarcomata.

Comparison with Tuberculosis.

When I was a student anthrax was taken as the standard of comparison in pathological mycology. Let us take tuberculosis as the standard of comparison in the study of malignant disease. The late Dr. Bristowe compared cancer with other infective diseases and stated that in his view every general specific disease begins as a local process. This is true of both tuberculosis and cancer. The clinical history of sarcoma or carcinoma is so closely akin to that of tuberculosis that it is quite within the truth to assert that there is no feature in the last-named disease which is not paralleled in the others. Before 1881 the authorities regarded tuberculosis as a disease with many causes. To-day some authorities regard cancer as a disease of many causes and the specific organism remains undiscovered. But the analogy between tuberculosis and cancer is perfect, and repudiation of the analogy leads only to despondency and despair.

The endemic location of cancer comprehending sarcoma and carcinoma, about which much might be said, is a highly remarkable fact in the history of malignant tumours.

The phenomenon of atavism has been observed both in tuberculosis and cancer. "Parents seemingly healthy may beget a family of children who all die of phthisis. The taint is latent in transitu." It is within my knowledge that whilst the first and third generations of a particular family were devastated by cancer, the second wholly escaped. Paget wrote: "The tendency which exists in the parents may never become in him or her effective, although it may become effective in the offspring." These events appear result from temporary impoverishment of the peculi soil; or the atavism might depend not on the subje but on the parasite itself, the life of which mig present an instance of alteration of generations. T phenomenon indeed may be comparable to that whi necessitates in agriculture a rotation of crops. carcinoma the primary tumour is seated mo frequently at sites where an infection from witho would most readily take place. The metastasis lymphatics or blood-vessels in carcinoma or sarcon is such as occurs in tuberculosis. It may be restrict to the lymph glands or be as widespread as a generalis tuberculosis (general sarcomatosis or carcinomatosi Even the glandular infection which occurs at times tuberculosis without primary lesion has its counte part in the squamous-celled carcinoma of the inguin glands in chimney-sweeps, in whom there may no discoverable primary growth. The latency glandular infections is equally represented in tub culosis and carcinoma. The sarcoma that grows the end of a long bone after injury is comparable wi the tuberculous osteitis ensuing under similar circu stances. Injury is the partial factor; the oth factor in the case of tuberculous osteitis we know be a specific virus. The relation of injury to tumo growth is illustrated by the case of a patient who f striking the forehead against a sharp iron spike. T spike perforated the skull and brain. Death occurr eight months later. The cause of death was ange sarcoma of the meninges and brain. The patien brain would seem to have been inoculated at the ti of injury with the virus of malignant disease as sur as a tube of culture medium is inoculated by plungi into it a platinum point deliberately charged wi infective material.

Carcinoma has sometimes a purely local origin the same way that a tuberculous infection may ar from direct inoculation. Take, for example, a case squamous-celled carcinoma of the lip. While stil local disease it may be completely eradicated. T case, in fact, is directly comparable to one of lo tuberculosis from direct inoculation or to exter anthrax, which is still a local process, and might termed one of local carcinomatosis. Local irritati and injury are sometimes spoken of as causes cancer. But this is not so. The efficient cause l beyond the irritation or injury which are but the part causes of the disease. The injury prepares a nutrie soil favourable for the growth of the tubercle bacil or the effective agent of malignant disease. Her itary predisposition or diathesis is nothing more th the presence in the body of a soil suitable for t growth and development of the virus.

Many examples of auto-inoculation have long be recognised, such as cæcal carcinoma, associated wi numerous lesser growths in the colon or an œsophag carcinoma associated with several small growths bel the primary tumour. These multiple small growt point to the possibility of an auto-inoculation of t same kind as occurs in tuberculous ulceration of t intestine. Such facts prove that the cancero epithelium has been transferred as a graft, but it do not prove the presence of a parasitic virus. It pro only that the cancerous epithelium cell or the ag which made it cancerous is infective.

When tubercle spreads through the body from primary lesion all the secondary lesions are typical f the disease and contain the virus of it. The spec anatomical characters of the secondary growths carcinoma are ample proof of their source from t primary tumour. In sarcoma the best proof of t same fact is furnished by the melanotic variety, wh the pigmentation of the secondary tumours is sufficie evidence of their origin from the primary growth.

Experimental Research.

After the rise of modern bacteriology strenu efforts were made to cultivate a specific microph from carcinoma. The results were uniformly ne tive. The failure of evidence in this direction to the suggestion that the hypothetical mic

asite might belong to the animal series, but the eriments in this direction were also negative. v is the infection communicated to the epithelium ne carcinomatous parasite is a protozoon? How he function of the first infected epithelial cell nged from a benign to a so-called malignant racter? It may be in one or more of the following 's: (1) By absorption of a chemical product ch is secreted by the parasite. (2) By the passage the epithelial cell of the organism, the latter ntaining a separate existence in the former. By the process of rejuvenescence in which the ging life of a protozoon is revived by means of on with another.

What happens to the epithelial cell first infected? ough single binary division is the chief mode of oduction another method of multiplication is by nipping off, or budding, of spores from the parent It is also not uncommon for a protozoon to ık up into from 10 to 100 or more pieces or spores. h piece contains all the elements of a perfect cell. he carcinomatous cell has a similar life-history pieces or spores of the subdivided epithelial cell each grow into an adult carcinomatous cell, or be thought of as conjugating with the surrounding nal epithelium, and of being the *fons et origo* in n of a carcinomatous rejuvenescence.

n sections of carcinoma there are certain appear- es in the cells which were thought years ago to cate the presence of a protozoon. I may cite the ers of Noeggerath, Soudakewitch, Foa, Ruffer, and lwig Pfeiffer. The opinion of Metchnikoff was that appearances indicated nuclear degeneration. I do know whether the virus of Gye belongs to the etable or animal kingdom, but if we suppose that as its habitat in the nucleus of the cancer cell (and e are some reasons to think that this is so, ugh at present the optical difficulties of demon- ting it seem insurmountable) it is possible that ie of the previous microscopical researches on the leus of the cancer cell may not have been all tless. Indeed it may be asked why should the lei of the actively growing cells at the periphery a malignant growth show signs of degeneration? failure to transplant human carcinoma to the er animals might be due to the fact that it is essary for the parasite to assume a phase outside human host in order to transmit the disease. s side of the problem has not been perhaps iciently explored.

s germane to this point Prof. Shattock and I carried a series of experiments with the object of seeing whether erimental infection could be brought about from the ospermial bodies so common in the rabbit's liver. We e led to do this after Darier's description of the presence sorospermia in the epidermis in Paget's disease of the le and the alleged association of psorospermia with inoma in general. The experiments were performed upon bits, monkeys, dogs, and rats. The chief experiments e performed on rabbits as being most likely to receive ction. Intravenous and other methods of introducing psorosperms were employed, but in no case was the nal infected.

f the positive results attained do not prove the stence in malignant tumours of an external agent must be borne in mind that the negative do disprove it. They show only that the methods ployed to demonstrate it were not suitable. method of transmission in infective diseases ot always so direct and simple as such grafting eriments presuppose. It has been shown, for mple, that malaria cannot be transmitted between ls by the injection of blood containing the hæma- oon. It has been shown, too, that the capsule of encapsulated protozoon consists at times of chitin of cellulose. Both of these substances are absent n the tissues of vertebrates. Further pathogenic teria produce in cultures albumose. Neither tin, cellulose, nor albumose can be demonstrated in arcinomatous tumour.

Though it has not been possible to transfer human cinoma to the lower animals it is well known t carcinoma can be transferred from animal to animal of the same species, and even from man to man.

One of the best and earliest examples of transference from animal to animal was recorded by Hanau, who successfully engrafted squamous-celled carcinoma from a rat into a series of other rats. In one experiment small portions of the tumour were placed in the abdominal cavity. Death ensued after three months and the abdominal cavity was found at the autopsy filled with nodules which presented the typical structure of squamous-celled carcinoma. Dr. Hanau showed me microscopical sections of the growth which was placed in the peritoneal cavity and also sections from the growing nodules taken after death from the peritoneal cavity. All the microscopical sections showed a squamous-celled carcinoma of the same type.

Since Hanau's experiment numerous investigators have worked intensively on the intimate pathology of cancer, and the discovery of the filterable viruses has opened out wider fields of research.

In 1913 Fibiger published a research on cancer of the stomach in rats. He was the first to cause experimentally a malignant growth. The ingestion of cockroaches infected with a special spiroptera, or the ingestion of the nematode larvæ obtained from the muscles of the cockroach, produced squamous-celled carcinoma in the cul-de-sac of the stomach. The eggs of the parasite were found free between the epithelial cells of the cancer. The cockroach is the intermediate host.

Virus or Enzyme.

In London at the conference debate on the ætiology of the disease the main discussion centred on the work of Rous, Borrel, Murphy, Gye and Barnard, and Leitch. Dr. Murphy said that now after many experiments the real nature of the cancer agent seemed to be emerging. He said that it was possible to extract with a considerable degree of regularity from the normal testes of the fowl a substance which, when injected into a normal fowl, would produce a malignant new growth. Dr. Murphy's belief is that the external agent is an enzyme, not a virus. Prof. Leitch supported the view of Dr. Murphy and stated that he had obtained a typical Rous sarcoma by the injection into a fowl of an extract of a normal fowl pancreas. The statements of Dr. Murphy and Dr. Leitch did not carry complete conviction to my mind. I am by no means convinced that the experiments of Murphy and Leitch constitute a final settlement of the work of Gye. Whether the causative agent is a virus, as Gye maintains, or an enzyme, as Murphy and Leitch hold, its most remarkable quality is its specificity in action. This specificity enables it to produce invariably the same type of tumour as that from which the agent was obtained. What does emerge is that the best workers in this field of pathology are agreed that there is an external agent concerned in the production of cancer.

Sir William Bragg, in an address to the British Association for the Advancement of Science last month, reminded his audience that in the nineteenth century light was regarded as a series of waves in an all-pervading ether. This theory was based on profound mathematical analysis and brilliant and far-ranging observations. Sir William added that there is no question of its truth in the ordinary sense. But in the twentieth century a new field of optical research had been opened up and had led to the inference that light had many of the properties of a stream of minute particles. This theory has passed the experimental test, and many experimental facts, inexplicable on the wave theory, are explained by the particulate theory. But how can anything be at once a wave and a particle? As yet there is no hint of reconciliation.

The dilemma is a rift in the whole fabric of scientific certainty. Is not the biologist in the study of the nature of cancer up against a dilemma which may be compared to that which now agitates the physicist? Virus or enzyme? Particle or wave? But there is hope of escape, as the *Times* suggested, for the scientific methods which have revealed it are still only scratching the face of the unknown. When bacteria were first recognised as the cause of disease it was thought that their presence alone induced

the disease. It was not till later that disease was discovered to be due to a specific chemical poison secreted by the bacteria. What is an enzyme? I do not know, but I do know that any active substance in the body—for example, a ferment—is manufactured by a living cell. This truth brings the virus and enzyme theories into close relation. Spontaneous generation being excluded, the crucial question is: What of the cell which manufactures the enzyme of Murphy? I am indebted to Dr. C. H. Andrewes for permission to refer to his work, which will be published this month.[1] He has repeatedly precipitated vaccine lymph and the final extract remains effective in the production of vaccinia. Dr. Andrewes states that the process can be repeated indefinitely. No one can suppose that the globulin precipitates are, *re* globulin, the cause of vaccinia. It is clear that the virus has passed through all these stages of the purification of the original material without losing its specific character. In the same way I suggest that the frequent precipitations employed by Murphy in the case of the extract of fowl testes, which he believes frees the resulting fluid from the virus of malignant disease, fails to do so. The reasonable conclusion is that the precipitated neo-protein carries the virus with it. The fact that in certain cases the virus of fowl sarcoma is to be found in the testes of this creature presents little difficulty to my mind. It is only an interesting observation, for we know that the organisms of disease lie latent in our bodies. Otherwise it would not be possible to explain after injury to the testicle or to a joint the occurrence of tuberculous epididymitis or tuberculous arthritis.

The rare tumour chorionic carcinoma occurs in the uterus and occasionally in the Fallopian tube and ovary. When the Fallopian tube or ovary are affected it may be presumed that these organs have been the seat of early ectopic gestation. The tumour occurs at any age within the limits of possible pregnancy. It would seem that the spermatozoon carried with it into the mature ovum not only its natural growth-producing power, but also the external agent of carcinoma. It is possible that the spermatozoon in chorionic carcinoma is the host of this agent which is the essential cause of carcinoma. As germane to this view, it may be remembered that chorio-epitheliomatous elements are found in certain testicular tumours.

When I entered the profession the members of the Pathological Society of London were engaged at their meetings in showing specimens of disease obtained from the post-mortem room. But the times were changing. The work of Pasteur and Lister had begun to permeate the profession. Anæsthesia had been discovered. Gross disease could be examined in vivo and not only on the post-mortem table. The great age of dead meat pathology was passing away and in its place a living pathology was arising whose aim was the study and discovery of the intimate causes of disease.

I have already mentioned that as a working hypothesis in the search for the cause of cancer I pin my belief to an external cause. In all diseases where the pathological anatomist has the authoritative voice intrinsic causes are sought after and extrinsic causes are relatively neglected. The idea of a specific extrinsic cause of any disease has owed its origin either to non-medical men like Pasteur or in later times to bacteriologists; pathological anatomists have never embraced the idea enthusiastically. Indeed they have generally resisted any encroachment from this direction upon their special domain. I remember the opposition of the great Virchow to the opinion that tuberculous disease owes its origin to a specific microbe; his opposition, in spite of his unrivalled authority—an authority no man could support now—was broken down because of the relatively simple and easily verifiable bacteriological findings of Koch. If the demonstration of the tubercle bacillus were entirely dependent upon animal experimentation of a complex character, depending f interpretation upon acute insight into the path logical problem, and upon scientific imagination estimating probabilities, I doubt whether to this d the opposition, now proved to be reactionary, of t morbid anatomist would have entirely disappeared.

In 1880 I attended a lecture by Sir John Burd Sanderson. The subject was the Nature of Scrofu He described how he had gathered dust from S Paul's Cathedral, from Westminster Abbey, and fro his own drawing-room, and how it had been plac under the skin of a series of guinea-pigs. The resu we were told, was that all the guinea-pigs we infected with scrofula, and that the disease could n be a specific one, as the specific agent could not supposed to be in all these three places at the sa time. I and my friends left the lecture theatre feeli that the argument was not conclusive. The followi year Koch demonstrated the tubercle bacillus.

Limitations of Morbid Anatomy.

In considering the problem of the cause of can I am not disposed to attach great weight to t opinions of those who merely study appearances dead tissues under the microscope. I accept with d thanks their contribution towards the pathologi definition of the fine structure of the cancer cell, b I am not prepared to be governed by their theori It is to animal experimentation that we must look f the solution of this mysterious problem. The pione of cancer investigation—Jensen in Denmark, Bor in France, and Loeb in America—confirmed t earlier studies of men like Hanau who had sho that animal cancer differs in no respect from hum cancer and may be transmitted from animal to ani by the process of grafting. They showed, howev as the late Prof. Shattock and I did, that all t cancers studied gave no evidence of a cause separa from the cell. The cell appeared to be the indivisi unit of the disease. These observations, confirmed experimenters all over the world and especially on large scale and with great exactitude by Bashford a Murray in London, gave no encouragement to th who believed in an extrinsic cause of the disea Some were overwhelmed by the apparent completen of the proof—or really by the absolutely negati character of all attempts to find an extrinsic cau Even Borrel, one of the earliest and most energe pioneers and a believer in the microbic cause, w nearly swept under by the wave of confident dogmati which teaches that the disease cancer is a cell in whi nuclear degeneration independent of microbic activi has occurred. Borrel was never able to accept t sweeping conclusion and endeavoured to res orthodox opinion. He stood almost alone for a lo time, neglected and powerless.

The tremendously strong dogmatic world-opinion still uppermost, but not all-powerful. Murmurs discontent with the stagnant stage of cancer resear have been heard in every country. In England t formation of the British Empire Cancer Campaign ow its origin largely to the existence of the feeling th new blood was required to study afresh the origins cancer. Doubtless in America you have felt somewh similarly. This murmuring of opposition to t authority of the pathological anatomist has fou expression in attempts to get behind the problem cancerous growths by instituting departments biophysics, biochemistry, and so forth. But it not very likely that the true solution of the probl will come from oblique investigations. The study cancer must be direct. But since the investigatio of cancer institutes have proved so barren in th negativeness, where shall we look for the lead in t great problem?

During the last three years there has been mu discussion and more criticism of the researches of r countryman Gye. Now I should like to express r views on this matter. At once I must make it cl that I am not competent to discuss all the details such work; I can give the reflections of one who h witnessed the fluctuations of medical opinion duri

[1] The paper referred to was published in the Jour. Path. and Bact., October, 1928.

years and has seen that which was abused, epted, and proved true.

can look back to a period of research beyond that ch embraces the lives of most of my hearers. ave heard Virchow, Helmholz, and Ludwig lecture, I have seen Pasteur and Lister and Paget at k. I was a distressed and angry witness of the position and abuse which assailed Pasteur and ter in the early days of their immortal labours.

he first point in Gye's work is this, that he sees lead in cancer investigation to lie in the study of remarkable group of fowl tumours which were brought to light by Dr. Peyton Rous, of the kefeller Institute. They are the exceptions in cers in this, that they give evidence of a cause; , as has happened so often, exceptions to general s are likely to yield new knowledge which extends eral laws. The work of Peyton Rous in proving the plastic nature of these fowl tumours has been perly acknowledge by Gye, who has sought to erstand the nature of the cause of these tumours to link together the fowl and the mammalian nours.

he essential claim which Gye makes is this, that clear cell-free filtrate which is obtained by acting a fowl tumour with saline, and which tains the tumour's cause, is not a simple single g. The "agent" of the tumour is complex. Now the experiments which have been published in support of this contention have met with but little support. But if one takes into consideration the very, very delicate nature of the tumour agent, the fact, for example, that it disappears or becomes impotent after mere incubation at 37° C. for a few hours, and that it is only demonstrable with the highest power of the microscope and with the use of ultra-violet light, it is easy to understand that the difficulties of the work are very considerable. Gye believes that the evidence he has adduced is good enough, at least as a first approximation to the truth, to show that the virus found in the fowl tumours is common to many animal and human tumours.

Conclusion.

I cannot form a definite opinion upon all these technical matters, but I have been for 50 years intensely interested in, and have done a little work on, the problem. I would put forward this point for your consideration. It is not sufficient for anybody who is deeply concerned with the cancer problem to be merely destructive in criticism; it is the duty of critics to find some other explanation of the peculiarities of the cancer problem if Gye's turns out to be wrong. At present it is the only explanation which fits together a series of apparently irreconcilable observations.

THE DIAGNOSIS OF EPTOMENINGEOMA OF THE SPINAL CORD.

WITH A REPORT OF THREE CASES SUCCESSFULLY TREATED.

By THEODORE THOMPSON, M.D. Camb., F.R.C.P. Lond., F.R.C.S. Eng.,
PHYSICIAN TO THE LONDON HOSPITAL.

[OST organic lesions affecting the central nervous em are progressive, do not readily respond to tment, and carry with them a grave ultimate gnosis. The treatment consequently becomes iative. This, however, is not true of lepto- ingeoma of the spinal cord, where the treatment, if ied out early, leads to cure. The importance of y diagnosis, therefore, becomes paramount. It is when surgical measures are resorted to before plications are superadded and permanent damage resulted from compression of the cord that we promise the patient permanent relief from the ressing symptoms. Before emphasising certain ortant factors presented in the symptomatology his condition, a report is given of three cases essfully treated.

The First Case.

spinster, aged 50, first came under my care in August, . At the age of 14 she had had tuberculosis of the right v and left foot, which had necessitated excision of the v-joint and amputation of the left big toe. She had enjoyed good health until May, 1921, when she com- ied of backache. The pain, situated in the centre of back in the mid-dorsal region, was severe and occasion- sharp and accentuated on movement. There was at time no weakness nor sensory disturbance in the lower mities, and no history of bladder trouble. Muscular r and sensory function in all the limbs were normal; plantar response was flexor and the knee-jerks were slightly exaggerated. X ray examination of the back osed osteo-arthritis of the spine with prominent lipping e vertebral bodies.

ith a diagnosis of osteo-arthritis of the spine, the nt was sent to Buxton for treatment. Whilst there noticed numbness in the lower part of the abdomen, nencing on the right side and later spreading to involve feet. This was followed by weakness in the legs cially the right) resulting in great difficulty in walking pain in the back was severe only on movement and ined localised, and accompanied by local tenderness. modic movements of both legs prevented the patient sleeping at night. These symptoms increased, and when she was re-examined on Oct. 2nd, 1921, there was complete loss of power in the right leg and considerable weakness of the left. Both limbs were spastic, the deep tendon reflexes were increased, abdominal reflexes were absent, and the right plantar response was extensor. Ankle-clonus was present on the left side. There was complete loss of sensation to pain, heat, and cold on the left side as high as the ninth thoracic segment, while on the right side there was numbness to pin-prick only. For the past three days the patient had experienced difficulty with micturition, and for 24 hours there had been complete retention. Four pints of urine were withdrawn by catheter.

A diagnosis of spinal tumour was made, and on Oct. 5th laminectomy was performed by Mr. A. J. Walton. A localised tumour, exposed between the seventh and eighth thoracic segments, was found compressing the spinal cord and was easily removed. (Fig. 1.) The patient made a steady and uninterrupted recovery. A month after the operation she could move both legs and stand unsupported, and had regained complete control of the sphincters. Three months later she was able to walk a hundred yards without support and, apart from occasional cramp-like spasms in the legs at night, was free from any discomfort. She improved steadily, and ten months after the operation she had returned to work as head-mistress of a school with 130 girl pupils. In the summer of 1926 she had done a great deal of walking in Lugano, Chamonix, and Grenoble, including several "good climbs." When examined in January, 1927, the movements of the lower limbs were good, there was no rigidity, and the plantar response was flexor. A little numbness at the level of the seventh dorsal vertebra was the only sensory change remaining. When next seen, during the summer of 1928, her condition was excellent.

The specimen removed at operation was examined by Prof. Hubert M. Turnbull, who made the following report:—

Macroscopic Examination.—The specimen (S.D. 1646, 1921) was oval, measuring 2·5 × 1·5 cm. and 0·8 cm. in its greatest thickness. The surface was covered with delicate, blood-stained, fibrous tags. The cut surface showed a very thin, white capsule surrounding a moderately soft, pale brown, somewhat granular tissue, in which there were a few reddish brown areas and small cysts.

Microscopic Examination.—The mass was bisected, and one-half was fixed in 2 per cent. saline formaldehyde and embedded in paraffin. Sections were stained with Ehrlich's hæmatoxylin and eosin, by Van Gieson's method and Masson's modification, with Weigert's fuchselin and neutral red, by Perl's method, by the Weigert-Gram method, with Masson's trichromic stain C, and with Mallory's phospho-tungstic acid hæmatoxylin after Zenker's fluid. The portion of tissue is approximately semi-circular, the convex surface being an outer surface covered with blood and the straight surface a plane of incision. The tissue is in places compact, but is for the most part rarefied to a variable degree by œdema; small and large confluent, round cystic spaces lie within the most rarefied areas. It contains several areas of recent hæmorrhage and a very large number of cells

loaded with iron pigment. The compact areas are composed of interlacing bundles of parallel, spindle cells. The bundles enclose vessels, and the cells are usually directed in the long axis of the vessel. There is frequently a zone of polygonal cells immediately round the vessel; occasionally a zone of short spindle cells arranged radially. The nuclei are usually oval, being elongated and narrow in the long spindle cells. The nucleus has a delicate membrane, a close net of very delicate chromatin fibrils, and a few large nodes of small nucleoli. The spindle cells are very long and narrow. Their cytoplasm in ordinary stains appears to consist of longitudinal fibrils, and is ill-defined. In Mallory's hæmatoxylin numerous delicate, somewhat wavy fibrils are stained in places. Some of the vessels have a narrow wall of delicate, collagen fibrils. Most have a wide wall of hyaline collagenous tissue containing a few cells; the wall is usually sharply defined, but sometimes delicate collagen fibrils extend for a short distance between the surrounding cells.

In the rarefied areas the shapes of the cells become more clearly seen the more the cells are separated from one another, and sharply defined fibrils are conspicuous in Mallory's hæmatoxylin. Most of the cells are very large and have the form of long tapering spindles, spindles forking at one or both extremities, triangles with one or all angles extended, or pears with elongated stalk. Less common are cells which have little cytoplasm and are either of similar shapes with curtailed processes or approximately spherical. Fibrils course within the large cells, particularly along the margins, and the cytoplasmic processes end in very long fibres. Between the cells is an abundant feltwork of sharply defined fibrils. In places this feltwork is very dense; there the cells are usually scanty and small, and are occasionally definite astrocytes. The cystic spaces contain a tangle of delicate, feebly stained fibrils, and have no definite lining. The fibrils are dark blue in Mallory's hæmatoxylin, red in Masson's trichromic stain, and Gram-negative. The outer surface is bounded in places by a narrow zone of collagenous fibres among which are no elastic fibrils. Beneath the surface are a few veins with fibro-elastic walls, and one large muscular artery surrounded by a wide adventitia of stout collagenous and a few elastic fibres.

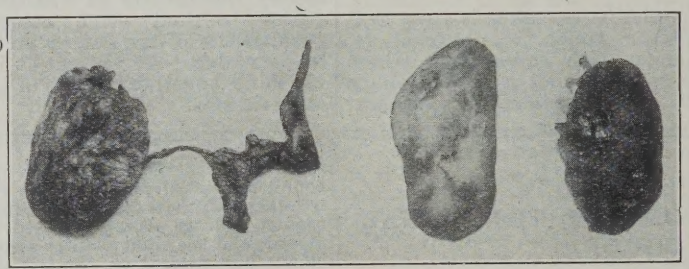

FIG. 1.—Tumour with portion of pia mater attached removed in Case 1.
FIGS. 2 and 3.—Tumours removed in Cases 2 and 3. (Natural size.)

The tumour consists of atypical neuroglia; it is therefore a gliosarcoma in the less restricted sense of this term. The enclosed artery is unlike the arteries within the spinal substance, so that the tumour involves the meninges and has probably arisen therein. The tumour is an intrathecal, hæmorrhagic, œdematous, cystic gliosarcoma, probably of leptomeningeal origin.

The Second Case.

Female, aged 48, first came under my care in January, 1927. She was married, with eight healthy children. For six years she had suffered from "neuritis" in the legs and feet, and for the last 12 months had noticed weakness and stiffness in the left leg and ankle, and these symptoms had slowly but steadily increased. She also complained of severe cramp-like pains in the calf of the left leg, frequently accompanied by uncontrollable spasmodic flexion at the knee. When walking she had noticed that the left ankle kept turning outwards, and for this reason she was believed to have flat feet. For two months the right leg had been numb and cold and the site of occasional sharp pain. There was also difficulty in commencing the act of micturition, but no incontinence.

The patient was a strong, heavily built woman. Examination of the heart and lungs disclosed no abnormal physical signs. The left leg showed slight general wasting and was cold, and gross spastic weakness of all movements was present. The right leg, although exhibiting slight spasticity, showed no obvious weakness. All the abdominal reflexes were absent, and the knee- and ankle-jerks were exaggerated on both sides, especially on the left. Both plantar responses were extensor. There was loss of sensation to pain, heat, and cold up to the level of the seventh thoracic segment on the right side, and these sensations were delayed in the left leg. Sense of touch was not impaired in either leg. There was gross impairment of sense of position in the left foot and some in the right. There were no sensory or motor changes in the upper limbs. The blood count was norm The Wassermann reaction in both blood and cerebro-spi fluid was negative. The cerebro-spinal fluid was not un pressure, was clear, and contained no excess of protei the cell count revealed 20 small lymphocytes per c.m An X ray examination of the spine revealed no abnormal in the vertebræ.

On Jan. 26th, 1927, 2 c.cm. of lipiodol were injected i the cisterna magna through the atlanto-occipital spa Subsequent radioscopic examination of the spine show that the lipiodol was held up at the level of the first thora vertebra for about two and a half hours (Fig. 4), t then it gradually trickled past, and that after three ho it had completely passed to the bottom of the dural s After the injection the symptoms became rapidly wo Two days later there was complete loss of power in b lower limbs; the pain and spasms in the legs had disappear and incontinence of both urine and fæces was present. sensory changes had increased in distribution, and a defi zone of hyperæsthesia was present at the level of the secc thoracic segment.

Laminectomy was performed by Mr. A. J. Walton Feb. 4th, 1927. Incision of the dura mater revealed a tum on the left side of s compressing the spi cord at the level the third thora spine. The tum (Fig. 2) was rea removed. The pati made a steady recov and soon regained c trol of her sphinct When examined May 31st, 1927, was able to stand supported and to w a few steps unai When last seen, October, 1928, she able to walk a dista of one and a half m without feeling t There was no and no difficulty micturition. When placing her feet in a warm bath still appreciated the heat more readily on the left than the right side. The tendon reflexes were present and e on both sides. Ankle-clonus was not elicited. The pla response on the left side was flexor, but extensor on right. Sensation on the left side was normal, but pin-p on the right side was only appreciated as touch up to level of the third thoracic segment.

The specimen removed at operation was exami by Prof. Turnbull, who made the following report

Macroscopic Examination.—The specimen (S.D. 1927) was received in formaldehyde solution. It was and measured 2·5 × 1·2 × 0·9 cm. One surface was co and irregularly nodular, the other flattened and sli concave. The surfaces showed a few fibrous tags, part larly the concave surface, and were yellowish-white ex for one glistening white area (0·6 cm. diameter), and b side a dark grey area (0·3 cm.). The cut surfaces white, mottled with a few irregular, greyish-brown a and faintly granular. On one cut surface was an are friable brown substance.

Microscopic Examination.—The nodule was bise One half was further fixed in 2 per cent. saline formalde and embedded in paraffin; sections were stained by same methods as in the preceding case. The section the oval shape with one flattened surface described ab but the convex surface is not nodular. The mass is posed of strands of spindle cells with narrow elongated nuclei, which stream in various directions and occupy periphery of large and small whorls of shorter spindle or rounded groups of lozenge-shaped or polygonal cells larger oval or round nuclei and less abundant cytopl Small whorls of concentrically arranged cells are com The rounded groups of polygonal cells bear a super resemblance to epidermal epithelium.

The nuclei have a deeply stained, slender membran abundant net of delicate fibrils of chromatin, nume small but conspicuous nodes, and one or more small nuc The nucleus usually occupies between a half and a thi the total area of the polygonal cells. The limits of the are usually very ill-defined, but are sharp where the are dissociated. The cytoplasm is stained readily; u high powers it has a finely fibrillated appearance, particu in the elongated spindle cells; but there are no de fibrils of fibroglia or neuroglia.

There are a few small vessels, with walls compos delicate collagenous fibres and an internal elastic memb

most of the vessels have a swollen hyaline collagenous
l containing a swollen elastic lamina or laminæ, and
e are transitions from partly occluded vessels of this
l to solid hyaline cylinders which are stained diffusely
Weigert's fuchselin. There are a few calcareous spheres,
ounded by a zone of hyaline collagen and elastic laminæ,
evidently formed within occluded vessels.
1 the central part of the concave surface is an area where
specimen has evidently been detached. All the rest of
surface is covered by a conspicuous layer of stout

grown-up children, and there had been no miscarriages. For seven months the patient had suffered from numbness of the feet, particularly of the left, and this had steadily spread upwards to the calves. A month later she complained of cramp-like pain in the left loin and occasionally in the left leg, and also a constant aching pain in the middle of the back, which radiated round to the left side and became worse when in the recumbent position. There was also some weakness and stiffness of the lower limbs. There had been no sphincter trouble of any kind.

FIG. 4.

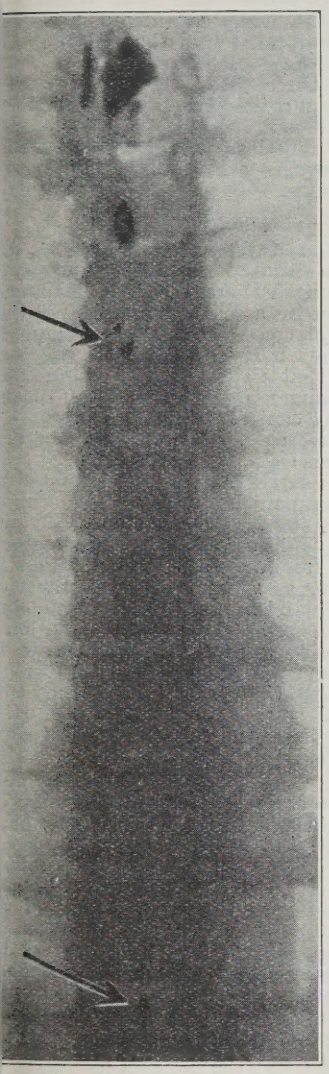

FIG. 5.

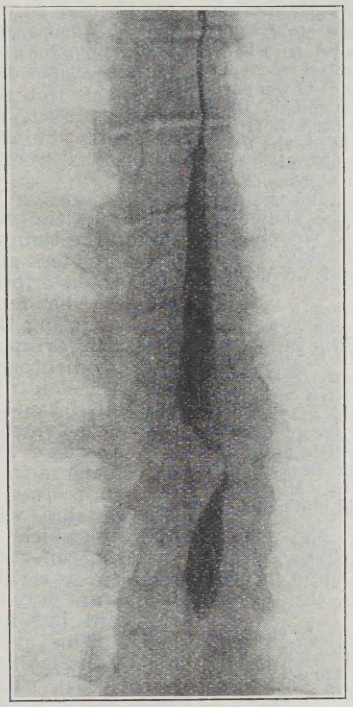

FIG. 6.

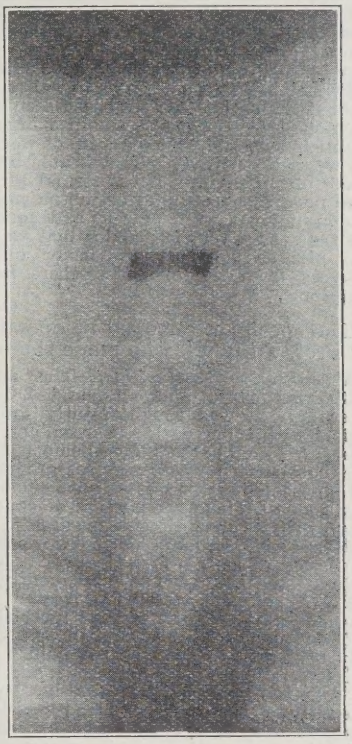

FIG. 4.—Film taken two hours after lipiodol injection in Case 2. The lipiodol is held up at the level of the first thoracic vertebra. The arrows indicate droplets of lipiodol falling to the sacral level.

FIG. 5.—Film taken three-quarters of an hour after lipiodol injection in Case 3. There is delay at the eighth thoracic segment and the lipiodol stream is deviated to the right.

FIG. 6.—Illustrating the appearance of the arrested lipiodol in a case of intramedullary neoplasm.

inæ of collagen, each of which is covered by elastic
ils. The inner laminæ are usually separated to a greater
esser extent by groups of cells similar to those already
cribed, and in a few places these cells extend right through
fibrous layer to lie upon the surface. Elsewhere the
er laminæ are closely opposed, and very narrow spindle
s lie between them.
'he tumour has the characteristic appearances of an endo-
lioma of the meninges, is covered by dural tissue, and
evidently projected like a mushroom with short stalk
n the inner surface of the dural theca. It is a cylindro-
tous, slightly psammomatous endothelioma of the dura.

The Third Case.

'emale, aged 56, a widow, first came under my care in
ruary, 1927. She had always enjoyed very good health
il two years previously, when she became very worried
l run down owing to her husband's illness. Twelve months
r he died of tuberculosis. There were two healthy,

The patient was a tall, thin, intelligent woman. There was no evidence of disease in the heart, lungs, or abdomen. The cranial nerves were normal. There was no weakness of the upper limbs, the tendon reflexes were present and equal, and there were no sensory changes. The abdominal reflexes were absent on the left side and present in the upper segment only on the right side. There was slight spasticity of both lower limbs, together with weakness, affecting especially the extensors of the legs and feet. There was no wasting. The knee- and ankle-jerks were exaggerated. These signs were more marked on the left side. Both plantar responses were extensor. Ankle-clonus was not elicited. Sensory changes were marked. A band of hyperæsthesia encircled the waist at the level of the eighth thoracic segment. Sensation to pain, heat, and cold was diminished in the right leg, and delayed in the left leg. There was gross impairment of sense of position in the left foot, but none in the right. The Wassermann reaction in the blood and cerebro-spinal fluid was negative. The cerebro-spinal fluid obtained by lumbar puncture was

clear, not under pressure, and contained an excess of protein and 65 small lymphocytes per c.mm. X ray examination of the spine revealed no abnormality.

Whilst in hospital she became progressively worse, and on March 3rd, 1927, developed retention of urine, which was relieved by catheterisation. On March 5th radiological examination after the injection of 2 c.cm. of lipiodol into the cisterna magna demonstrated the fluid passing down to the level of the eighth thoracic segment, where it was delayed for half an hour; afterwards the lipiodol stream was seen to deviate to the right and to pass down unobstructed to the sacral region (see Fig. 5).

On March 9th laminectomy was performed by Mr. A. J. Walton. On opening the dura a well-defined firm swelling was exposed at the level of the eighth thoracic segment, loosely attached to the leptomeninges and dura on the left side and posterolateral in position. Between the tumour and the dura was a definite bony plaque. The cord itself was flattened and pushed to the right. The general features of the tumour are illustrated in Fig. 3. The patient made a steady and uninterrupted recovery, and within six weeks was able to walk a distance of ten yards without support. She was last seen in November, 1928, when she stated that she was in charge of a large boarding establishment and that, in spite of working hard, she never felt wearied or tired. She was able to walk six miles with ease. She presented no abnormal physical signs. There were no sensory changes or motor weakness, and the deep tendon reflexes were present and equal. The abdominal reflexes over a very lax abdominal wall were not elicited. The plantar response was flexor on both sides. Since recovery from the operation there had been no urinary symptoms.

The specimen removed at operation was examined by Prof. Turnbull, who made the following report:—

Macroscopic Examination.—The specimen (S.D. 485, 1927) was ovoid and measured 2·2 × 1·5 × 0·8 cm. The outer surface was rough, faintly lobulated, greyish-pink flecked with a few dark red areas, and soft, except over an area (1·5 × 1 cm.) where it was smooth, yellowish, and hard. The cut surface was granular, greyish-pink flecked with red, and soft, except beneath the smooth area. Here there was a small triangular portion of cancellous bone (0·4 cm. long), with its apex directed inwards.

Microscopic Examination.—Two portions were fixed in 2 per cent. saline formaldehyde; one portion, which included the bone, being subsequently decalcified in nitric acid. Paraffin section were treated as in the previous two cases, and also by Kossa's method.

The tumour resembles that in Case 2 so closely that it is only necessary to describe the points of difference. Veins and arterioles are more numerous, and there are a few areas of recent hæmorrhage. Hyaline collagenous cylinders, evidently derived from blood-vessels, are much more numerous. Most of these contain a central core of calcium, which in cross-section usually shows concentric lamination. The outer surface is ragged and broken, except in one small area where it is covered by a thick membrane composed of collagenous laminæ, each covered by elastic fibres. Definitely within this membrane is a small portion of lamellar bone containing a Haversian space and two Haversian canals. Several of the elastic sheets in the membrane are continued into the bone. Immediately beneath the membrane, and covered laterally and inferiorly by a narrow layer of collagenous and elastic fibres, is a small triangular portion of bone containing many lamellar systems. It contains a few Haversian canals and several large spaces, which contain wide capillaries in a loose-meshed fibrillar, partly fatty marrow.

The bone appears to have developed within the inner part of the dural theca. The tumour is an endothelioma of the meninges attached to the inner surface of the dural theca. It is an extensively cylindromatous and psammomatous endothelioma of the dura.

Diagnosis.

No hard-and-fast rules can be formulated and applied to the diagnosis of leptomeningeoma of the spinal cord. The nature and character of the symptoms and the subsequent course of the disease cannot be accurately separated into definite stages or periods. The symptoms and the physical signs elicited in any particular case must depend on: first, the site of the tumour; secondly, its rate of growth; and, thirdly, the extent of the injury to the spinal cord produced by the growing neoplasm. Subdivision into the three stages of: (1) root pain, (2) Brown-Séquard syndrome, and (3) complete paraplegia with incontinence of urine and fæces, must consequently be regarded as artificial, and can be of no real value in the study of the condition. Before recourse is made to special methods and aid a study should be made of the clinical features available. In surveying these, certain of the features presented by the three cases reported here will be emphasised.

Level of the Lesion.—Learmonth,[1] in an exhaustive study of 60 cases, found that 63·4 per cent. of leptomeningeomas of the spinal cord occurred in the dorsal region. The tumours in the three cases reported here also occurred in the dorsal region of the cord, one in the upper and two in the lower segment.

Age-incidence.—The condition appears to be more prevalent during the middle and later decades of life. The ages of the cases considered here were 50, 48, and 56. Learmouth found that 48 out of 60 occurred between the ages of 30 and 60.

Sex-incidence.—All three cases were females. The literature also discloses a tendency for the condition to affect the female sex. In Learmonth's series 66·7 per cent. were females. Frazier [2] collected a series of similar growths and found that out of 37 cases 26 were females.

Symptomatology.

Pain is the commonest presenting symptom, but should the tumour be situated anteriorly this may be absent or less pronounced than where the tumour is placed posteriorly or in a postero-lateral position. Bennett [3] has recently placed on record four examples demonstrating the variability of the pain, the cases presenting symptoms that suggested osseous, muscular and ligamentous changes rather than any pathological lesion of the central nervous system. As illustrated by the three cases under review, the pain may be of three types:—

1. *Localised Pain.*—Here the pain, accentuated on movement and accompanied by marked localised tenderness over the spinous process, is situated over the vertebra which is innervated by the segment opposite which the tumour arises and produces its irritating effects. Its presence, therefore, must be regarded as a valuable and important symptom, since it may not only be the earliest indication of a lesion of the cord but may also accurately demonstrate its level. This symptom was a prominent feature in Case 1 and led to the provisional diagnosis of myositis or neuritis. The X ray examination still further obscured the true nature of the condition by revealing the presence of osteo-arthritis of the spine.

2. *Radiating Pain.*—This originates from the pressure of the tumour on the posterior roots; it may be dull and aching but is sometimes described as sharp, shooting, or stabbing, and radiates round the corresponding side of the body. Here also the pain is usually accentuated on sudden movement, and again proves a valuable aid in localising the level of the lesion. It appeared as a prominent symptom in Case 3, although paræsthesia had been present for one month before its onset. A zone of hyperæsthesia may be a manifestation of pressure upon posterior roots and may also indicate the level of the lesion.

3. *Removed Pain.*—This is manifested by the presence of cramp-like pain, frequently accompanied by spasms, in the homolateral lower limb and associated with some degree of numbness and weakness. The explanation of this phenomenon is given by the study of the mechanism of spinal compression by spinal tumours. Purves-Stewart and Riddoch pointed out that the pathological effects of the actual pressure on the cord-elements are very limited and that the widespread interference with cord function is due to vascular changes setting up what they termed a condition of anoxæmia. This engorgement of the spinal veins below the level of the tumour resulting in the depletion of the oxygen-supply to that portion of the cord, probably explains the presence of pain, numbness, and weakness in the lower limbs.

These symptoms, as illustrated by the cases reported here, may be present and persist for many months before the onset of more distressing symptoms.

Weakness and Subjective Sensory Symptoms.—bjective motor disturbance in the form of weakness d stiffness of one limb usually follows other sub-ctive symptoms, but in Case 2 loss of power and iffness in the left lower limb proved to be the esenting symptom. With the further growth of e tumour the conducting tracts on that side of the rd are interrupted, resulting in a progressive ralysis of the muscles supplied by homolateral gments below the level of the lesion, and a loss of nsation to pain and temperature on the contra-teral side. The sense of passive position may be terfered with, but only very rarely is tactile sensi-lity affected. When one half of the spinal cord is terrupted, the clinical picture known as the Brown-quard syndrome may be present. Such a condition, wever, is rarely seen, as a paraplegia soon ensues. "reversed" Brown-Séquard syndrome, where the otor and sensory disturbances are opposite to those scribed above, is seldom met with. The pressure erted by the growing tumour affects the extra-ramidal as well as the pyramidal tracts and a ralysis in flexion results. The spasticity is very arked and the rigidity persists during sleep and, as Cases 1 and 2, spontaneous and painful spasms ay be prominent and frequent. When the state of asticity passes into a condition of flaccidity with sence of superficial and deep reflexes, it is doubtful ether removal of the lesion will lead to a complete covery, permanent damage having taken place in e tissue of the spinal cord.

Vesical Symptoms.—Sphincter trouble had resulted each of the three cases reported here before they me to operation. Learmouth, from a careful alysis of his series, concluded that there was little lation between them and either the level of the mour or its position relative to the cord.

Additional Aids to Diagnosis.

Although the clinical examination, together with e history obtained from the patient, supply the ost important data upon which a diagnosis is based, evertheless valuable confirmatory evidence may be tained from accessory methods.

1. *Examination of the Cellular Content and Chemical roperties of the Cerebro-spinal Fluid.*—It is generally sumed that the cellular content of the cerebro-spinal uid below a spinal block produced by a non-flammatory lesion such as a neoplasm remains altered. Such a finding, however, is inconstant d unreliable. An increase in the cellular content as a marked feature of Case 3.

As a further result of engorgement of the spinal ssels below the site of compression, their perme-bility becomes increased and transudation occurs. he pigment of the altered blood gives the cerebro-inal fluid below the level of the lesion a charac-ristic yellow colour known as xanthochromia. Its esence, however, is not constant, and it was absent the three cases described here. Moreover, it has equently been recorded in other conditions.

The normal protein content of the cerebro-spinal uid is approximately 25 mg. per 100 c.cm. Below e site of spinal compression it may be increased up 2000 mg. per 100 c.cm. This increase in the otein associated with no increase in the cell count as held by Nonne [5] to be strong evidence of the esence of a spinal cord tumour. Similarly, an crease in the glucose and mineral salts may be oted.

The fluid below the site of compression may also ow spontaneous coagulation owing to the presence f fibrinogen. This property, along with the presence f xanthochromia and high protein content, combined ith a normal or but slightly raised cell count, was rst described by Froin,[6] and these signs are collec-vely designated the "loculation syndrome."

Finally, as pointed out by Purves-Stewart and iddoch, fluid in an isolated sac of the spinal rachnoid space is separated from the source of any rments passed into the space from the choroid lexus and the pituitary body.

2. *Study of the Combined Cisternal and Lumbar Puncture.*—Normally the composition of the fluid should be constant throughout the subarachnoid space. When a spinal subarachnoid block is established, the composition becomes altered in the way described above. Ayer [7] elaborated a method by which the fluid above and below the lesion can be studied. Needles connected to manometers are introduced into the cisterna magna and the lumbar region of the space with the patient lying on his side. Stookey [8] and others, following their study of manometric readings in 50 suspected cases of spinal cord tumour, stated that combined lumbar and cistern puncture is indicated when manometric studies from the lumbar puncture alone do not permit of definite conclusions, and that in their series the combined method was only necessary in three instances.

3. *Manometric Studies of Cerebro-spinal Fluid through Lumbar Puncture.*—In 1916 Queckenstedt,[9] by means of lumbar puncture alone, demonstrated that the pressure in the subarachnoid space was raised after compression of the jugular veins in the absence of spinal block, but that when obstruction was present the response to the general methods of raising the general pressure in the space was altered, lessened, or absent. Stookey has emphasised the value of this method in the investigation of spinal cord tumours, and considers the examination incomplete if a manometric study has not been conducted.

4. *Injection of Lipiodol into the Spinal Theca.*—This method of investigation, first introduced by Sicard and Forestier,[10] has provided us with a further valuable aid in the study of spinal cord compression but, as recently emphasised by Armour,[11] its use should in no way usurp the place of careful and repeated systematic clinical examinations of the patient.

With the patient sitting upright, 2 c.cm. of lipiodol are injected into the cisterna magna. In the absence of a block the fluid falls to the lower end of the spinal theca in two to seven minutes. When the offending lesion has established a subarachnoid block, the lipiodol may be completely arrested above the site of the tumour for a long time, and later commences to trickle down to the lumbo-sacral portion of the sac. Figs. 4 and 5 illustrate the results obtained in the investigation of Cases 2 and 3 by this method. The value of lipiodol is greatest when the level of its arrest corresponds with the level of the tumour, as determined clinically by sensory changes. In addition, the outline of the lower border of the shadow of the arrested fluid may suggest the nature of the tumour. Thus in a case of extramedullary compression the lower end of the shadow may taper to a thin point where the lipiodol slowly trickles through (Figs. 4 and 5), whereas in cases of intramedullary growths the lower border of the arrested fluid assumes a more uniform outline, which tends to be crescentic with its concavity downwards (Fig. 6).

The injection can also be made into the lower end of the spinal theca by lumbar puncture. This method is simple and free from the risks entailed in cisternal injection, but it requires a special table and has a further disadvantage in that many patients cannot tolerate the reclining position which is necessitated by the test for a period of 10 to 20 minutes.

The use of "light lipiodol" has not gained universal favour, and it possesses no great advantages over the methods already described.

Various complications have been attributed to the use of lipiodol in the investigation of spinal compression from extramedullary tumours. After the injection in Case 2 the symptoms became rapidly worse and complete paralysis of both lower limbs, together with incontinence of both urine and fæces, ensued. Lipiodol, therefore, should not be used unless the patient can be operated on soon after, should necessity arise.

When such conditions as meningovascular syphilis, intramedullary neoplasm, and syringomyelia, together with pathological changes in the vertebræ have been excluded, and recourse to the special methods defined above has established the diagnosis of lepto-meningeoma of the spinal cord, the condition becomes

a surgical emergency and operative procedure should be adopted immediately. If operation is unduly delayed permanent degenerative changes may occur and lead to irrecoverable damage to the conducting fibres within the cord.

I am indebted to Prof. Hubert M. Turnbull and Mr. A. J. Walton for their help in elucidating my cases.

METHODS OF TRACHEAL INSUFFLATION

AND INTUBATION INHALATION OF ANÆSTHETICS.

By W. HOWARD JONES, M.B., B.S. Lond.,

SURGEON ANÆSTHETIST TO CHARING CROSS HOSPITAL; SENIOR ANÆSTHETIST TO LONDON TEMPERANCE HOSPITAL, ROYAL EAR HOSPITAL, AND ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

When Meltzer and Auer experimented upon animals in 1909 the advantages claimed by them for the method of tracheal insufflation were, first and foremost, that it was a safety method which would prevent the inhalation of fluid or foreign substances into the air passages; and, secondly, that an animal could be kept alive for a prolonged period when both pleuræ were opened, thus proving it to be a very efficient means of performing artificial respiration.

Complete and Partial Insufflation.

How far, in actual present-day practice, this is a safety method is a subject for serious examination. I propose to advocate strongly the adoption of a modified terminology, which is essential if students and others who take up this method are to be made aware of the very important differing conditions which exist in what I shall refer to as complete tracheal insufflation and partial tracheal insufflation. Complete tracheal insufflation means the passage of air or gas and oxygen into the trachea in such quantity that the patient's tidal capacity is more than satisfied, and that even during the inspiratory phase there is an outgoing current through the glottis. This is the Meltzer-Auer method and is the only one to which the term "safety" can correctly be applied, for if these conditions are not fulfilled and the patient can, during inspiration, draw air through the glottis, fluid may certainly be aspirated with it. Partial tracheal insufflation implies that an amount of air or gas and oxygen less in volume than the tidal capacity is passed in, allowing the patient to make up the deficiency by a to-and-fro movement of air through the glottis. Unaided, this is not a perfectly safe method; the same precautions against the aspiration of fluid must be taken as in an ordinary administration, and provision must be made to counteract any tendency to obstruction by the base of the tongue, or by any other impediment to a free airway. The patient is, in fact, at a disadvantage, because the normal protective reflex mechanism against inhalation of fluid or solid particles, present during light anæsthesia, is hampered by the presence of the catheter between the cords, and the epiglottis is out of action. Coughing consists of violent expiratory efforts followed by a long-drawn and equally violent inspiration, and it is at this moment that aspiration is most likely to occur. When once movement is set up in the larynx the catheter acts as a strong irritant until the reflex can be abolished. Partial insufflation is the method commonly in use, and its imperfect protection against inhalation has unfortunately been demonstrated in practice.

The tidal capacity is that amount of air which passes in and out of the chest during respiration. It corresponds with the difference in cubic content of the respiratory air-space between the range of expansion and contraction of the chest. It is indicated by the movement of a bag of gas or air when the face-mask is closely applied. It varies within wide limits, both in the same and in different subjects under varying conditions. It usually decreases in amount as the rate of breathing increases, and vice versa. The average amount of the tidal capacity is given in text-books as 500 c.cm., but it is sometimes very much more or, with quiet breathing and small chest capacity, much less. The rate of respiration during anæsthesia under favourable conditions may be little above the normal, but frequencies of 30 or more are met with. To calculate in litres per minute the rate of flow necessary for complete insufflation the tidal capacity must be multiplied by the frequency of respiration per minute, and the quotient must then be doubled, because the flow is continuous during the expiration phase and an excess must be provided for.

It is sufficient for my purpose to show that a very large flow may be required and that few, if any, of the small air pumps now in use are capable of putting up such a performance. A large foot-bellows will give an adequate flow, and it is noteworthy that this is actually a very good instrument to use, for with it a perfect artificial respiration may be maintained increasing pressure and flow during inspiration and decreasing during expiration. An anæsthetist's equipment should provide for maximum requirements and a good mechanical pump should be able to generate a large volume of air at low pressure.

The Size of the Catheter.

It is impossible at low pressure to pass a large volume of air through a catheter with a small bore and if the external dimension is too great it will act as a block against the return flow. The theoretical ideal is that the bore of the catheter should be a little less than the surrounding space in the trachea, so that a large volume of air can pass in at low pressure and return with equal freedom, allowing normal chest movements and the variation in cubic content which they involve. It is important to realise that the manometer indicates the pressure inside the catheter, and that this corresponds to that in the lungs only when there is a block against the return, or when the ingoing channel equals the outgoing. When the catheter bore is small in comparison with the surrounding space the manometer reading will tend to be higher than the actual pressure in the trachea, unless a block is put on the return.

Practical Applications.

Complete insufflation, although protective against inhalation dangers, is of little use in operations on the mouth which involve bleeding, on account of the impossible situation set up by the projection of blood and anæsthetic vapour in the face of the operator. It may be used in ordinary work, but only at very low pressure, or with variation in pressure corresponding to the respiratory phases. Low pressure complete insufflation requires an exact choice of catheters. Its real practical importance is that it should always be possible to convert a partial into a complete insufflation if fluid is ejected into the throat. Thus only will the patient be secure against aspiration until the pharynx can be cleared. It follows that in mouth operations some other method is essential, and the one commonly employed is the double catheter and pharyngeal pack or the single intubation inhalation method. When the double catheter is used the second, or exhaust

must be as large as possible, and the inlet catheter will on this account be smaller than it would be in the case of an ideal single catheter administration. The insufflation will, therefore, almost certainly be partial, and to-and-fro breathing will take place through the exhaust. In fact, all variation in chest capacity must necessarily take place through its channel. Now the largest possible lumen in these circumstances can only be but a poor airway compared with the normal, and the use of double catheters can only be looked on as a compromise necessitated by the circumstances of the operation, and in no way desirable, or superior to, the single catheter in ordinary cases. They are necessary whenever the anæsthetist has not complete control over the conditions prevailing in the upper air passages, or in a partial insufflation saliva can always be aspirated if the position of the head is favourable, and a mouth airway by no means provides a channel for breathing in all circumstances.

In the alternative method of intubation inhalation a large single tube is passed into the trachea and the pharynx is packed round it. The patient breathes through its lumen, and anæsthetic vapour is added to the ingoing tidal air by means of an adaptor on the end of the catheter. This is also a compromise and, unless the bore is large, the airway is obviously restricted compared with the normal. The frictional resistance to the passage of air through small tubes is considerable, and imposes effort on the patient. Signs of anoxæmia may develop, and it is always useful in this method to add oxygen to the ingoing air. Slow, deep breathing indicates high carbon dioxide tension. If anyone doubts the exertion involved in breathing through small tubes, let them make a personal experiment.

Now although, when the pharynx is packed, the patient is safe in respect to fluid from above, it must be remembered that fluid may be ejected from the stomach below the pack and be dammed in the neighbourhood of the glottis. It is essential, therefore, to maintain an even depth of anæsthesia and, if vomiting should threaten, the anæsthetist must be alert to deal with it.

Tracheal insufflation of gas and oxygen is a common procedure. It is evident that only with complete insufflation is it possible to maintain anæsthesia; for how, if the patient is breathing air as well, could such a mixture be effective? The large amount of mixed gases required for a complete insufflation makes this method unpractical. It follows that most of these administrations are partial, with the addition of ether, and if the gases are led through an ether bottle the procedure is practically an ether administration, using gas and oxygen as a vehicle.

Partial insufflation of gas and oxygen can be made practical by the use of a rebreathing bag, and this is a good method. Meltzer and Auer's second discovery is applied in intrathoracic surgery. Before closing the chest the lung has to be expanded so that it will fill the pleural cavity. The negative pressure in the pleura at full inspiration is given as 30 mm. of mercury, and the safety-valve is set to blow off at this pressure. If the catheter has been correctly chosen the lung may be expanded and held by a complete insufflation at this pressure without any interference with the return flow, but if, when the manometer shows this pressure the lung fails to expand, it shows that the catheter is too small, and a block must be put on the return flow. This may be done by applying an ordinary rubber face-mask, of which the aperture is occluded by a suitable metal fitting carrying a tap. This tap can be adjusted so that air may be continuously passed, while sufficient is retained in the lungs to distend them. Pressure on the lungs cannot be maintained for more than a short period. With the fixed chest alveolar ventilation depends entirely on diffusion and is inadequate. The alveolar capillary pressure will be very much lower than the air pressure; that in the large veins is normally only a few millimetres of mercury and, during inspiration, it tends to be negative. High pressure interferes with the circulation, and the venous return to the right auricle is impeded. This results in decreased output by the left ventricle, and the pulse becomes small. On releasing the pressure the pulse regains its former volume. This may be demonstrated on any case. High pressure insufflation is on this account bad practice, and is to be used only as occasion demands, and then only for a short period.

Occurrence of Apnœa.

It is frequently stated that apnœa is commonly produced by this method. Physiological apnœa is that condition in which, owing to excessive alveolar ventilation, the tension of carbon dioxide in the blood falls so low that it fails to excite the respiratory centre. There is another cause of stoppage of the breathing, for the centre may be rendered inexcitable to a normal amount of carbon dioxide, and this can be done very easily by drugs such as morphia, ether, and chloroform. This stoppage can be produced any time by ether and is sometimes seen when a patient has been difficult to relax and ether has been liberally used. When relaxation is attained the breathing ceases, or almost ceases. If ether is lessened or discontinued and insufflation of air increased the breathing will gradually be resumed at normal depth, thus demonstrating the cause of the stoppage. Tracheal ventilation in the absence of exaggerated chest movements does not lead to excessive alveolar ventilation. The characteristic features of this method are quiet breathing and the perfect colour of the patient. Normal breathing and good colour indicate that carbon dioxide tension is normal and that the depth of respiration is sufficient to carry oxygen to the alveolar air. There is, therefore, in ordinary circumstances no reason why true apnœa should occur, and I certainly have never been troubled by it. Any stoppage which can be treated by continued insufflation is certainly due to high ether tension and not to deficiency of carbon dioxide. It is possible that the Hering-Breuer reflex may contribute to a temporary hold-up in respiration, especially at the early stage mentioned above. Distension of the alveolar wall reflexly inhibits inspiration through the vagus. This condition is not an apnœa, but a prolonged respiratory effort in one phase.

Warming the Air.

The question of warming the air is, I hope, now settled. Patients receive the air at about room temperature, and this is what they require. It is odd that the most important consideration is generally overlooked; when air is insufflated it impinges on the moist surfaces of the air passages, and unless it is saturated with water vapour evaporation from the moist surface is inevitable. Heat is absorbed in the process of evaporation and is extracted from the surface. This is why the pharynx sometimes feels cold and the tongue may get dry. The cooling is proportional to the volume and rate of flow of the air current. It is the strongest argument which can be brought forward against large volume insufflation. If it is to be avoided the air must be moistened rather than heated. Fortunately, many thousands of administrations by many anæsthetists tend to show that there is no method more free from respiratory troubles than the one under consideration. If anyone is in doubt whether an administration is complete or partial, let a small flake of cotton-wool be placed in the pharynx or at the mouth of the airway, and this will show which way the wind blows.

A HOSPITAL'S COFFEE TAVERN.—Some years ago the London Midland and Scottish Railway presented the Euston Coffee Tavern at Crewe for the benefit of the Crewe Memorial Hospital. The tavern, which is managed by a committee of the hospital staff, has handed over £500 as the profits of the past year. Several thousands of pounds have now been paid to the hospital from this source.

A NOTE ON THE FREQUENCY OF SKI-ING ACCIDENTS.

By Dr. W. KNOLL,
Arosa (Switzerland);
PRESIDENT OF THE MEDICAL SPORT COMMISSION OF THE SWISS NATIONAL ASSOCIATION FOR PHYSICAL EDUCATION; PRESIDENT OF THE INTERNATIONAL MEDICAL SPORT UNION.

THERE recently appeared in *Punch* a humorous drawing designed to call attention to the frequency of injuries due to winter sports, especially ski-running. It may therefore be of interest to your readers to know what this frequency is in fact, and the following note sets out our experience at the winter resort of Arosa in the Swiss Alps, the data being complete up to the end of January, 1929.

The first communications on ski-ing injuries were made by Steinmann 1911, Oberst 1911, and Bernhard (St. Moritz) 1913. Then followed v. Saar, Mandl, Staehelin, Likint, Drevermann, Genewein, and Hug (references given at the end). Most of these simply narrate cases. Only Hug put together some figures on frequency, using material not observed by himself, but collected from ten insurance companies. I have had opportunity within the last six winter seasons in Arosa of observing personally 430 injuries occurring during ski-running. In addition, I have sent round a questionary for 1927–28 addressed to the ski-ing instructors to ascertain how many accidents occurred during practice and on conducted tours; these results have been published (reference at end).

Causative Factors.

From this material the salient facts are as follows. The kind and frequency of injuries to ski-runners undoubtedly depend on the degree in which they have mastered ski-ing, in other words, on good technique. Medical experience in general as well as the replies to the questionary addressed to instructors show that poor runners run a greater risk than middling runners, and middling runners a greater risk than really good runners. This observation conflicts with the conclusions drawn by Hug from material supplied by the accident insurance companies, according to which the expert runs an increased risk of accident. The discrepancy arises from the fact that instructors and guides make a rule of insuring, while only some 10 per cent. of the other members of the Swiss Ski Club are insured against accident. For the rest the good runners in consequence of their knowledge of the country and of weather conditions, together with their experience in the various kinds of snow get out of difficult situations without injury more easily than those with less judgment and experience. The risk of accident therefore steadily diminishes in proportion to the mastery of technique.

Apart from technique there are other circumstances which affect the frequency of accidents. One is imperfect visibility, especially in early morning and late evening, but also in dazzling sunlight, which makes it impossible for the runner to orientate himself even at a short distance. Then only very careful running can help him along with observance of every precautionary measure. In point of fact a disproportionate number of accidents are due to such circumstances. Another important factor is variation in the quality of the snow. It often happens that the runner suddenly passes from a crusted surface into deep powdery snow, and if his technique is not up to meeting the new conditions at once and correctly a fall is inevitable, although even then a fall rarely leads to accident. Furthermore, the precise way in which the fall happens is very important for the resulting injury; he who understands how to fall will run much less risk, even in severe falls, than he who does not understand. Masters in this art are not the grown-ups, but the children, who simply let themselves fall without making any effort to prevent it. This counts for much on a hard surface, which takes first place in responsibility for various forms of injury. For example, the torsion fractures of the metacarpal bones, described as very frequent in Central Switzerland from a fall on the hand which still holds the stick, only occur with us under quite definite conditions—namely, when for long no snow has fallen, when the slopes have become very hard, and when the tracks are iced. Then elderly runners whose technique is not very good are specially liable to incur severe injuries, particularly fractures and sprains in the region of the upper limbs.

The Common Injuries.

The large majority of all ski-ing injuries, of course, concern the lower limbs. Here, again, there is a definite correlation with changing snow conditions; when there is deep powdery snow sprains and tears of ligaments in the knee and ankle-joints predominate, whilst on a hard surface fractures of one or both legs occur much more frequently. The commonest leg injury is the torsion fracture of the fibula at its lower end. Supination fractures of the outer ankle occur, the method of production being typical and generally the result of the Christiania swing. Torsions occur more frequently in stemming and Telemark turning. In this connexion it may be mentioned the interesting fact that the injury often precedes the fall. The fall therefore is not its consequence but its cause. In a great number of these cases it is torsion of the body on a leg which is more or less fixed by the ski-binding or by the snow that is the immediate cause of the injury; a fact which is well illustrated by the case of a runner who, when lying on a slope where he was held fast, produced a torsion fracture of his fibula by a smart turn of his body.

Some difference occurs as between the sexes, inasmuch as the frequency of knee distorsion, which consists essentially in a tear (seldom in a complete separation) of the collateral tibial ligament with consequent marked abduction of the leg, largely preponderates in women—48·0 per cent. compared with 19·7 per cent. in men. On the other hand, the ankles were damaged among men in the proportion of 54·2 per cent. to 34·5 in women. The different relation of the axes of the thigh and leg, which allows in the woman much severer loading of the knee in the direction of genu valgum, may be regarded as the reason for his difference.

Prophylaxis.

On an analysis of the whole material 10·4 per cent. of all injuries concern the head and trunk, 14·8 per cent. the upper limbs, the whole of the remaining 74·8 per cent. falling on the lower extremities. Accidents attributable to equipment itself, skis, or sticks, are very uncommon with us because the favourable snow conditions do not give occasion for them. Yet I have among my material a small number of contusions from falling on the points of the ski and some stabs and contusions due to sticks. The great majority of all injuries occurred during the downhill run from disturbance of coördinated movement between the ski and the body, with resulting disturbance of equilibrium. The form and tightness of the binding certainly is a contributing factor, although in the absence of good material for comparison it would be impossible as yet to say whether this or that binding is more favourable for the avoidance of injuries in falling. Much weight is certainly to be laid on equipment. Bad equipment produces a greater tendency to fall, and frequent falls lead to local and general fatigue which results in a greater risk of accident. This must also be considered in the choice of participants for a tour, for when a man with little technical experience makes a considerable tour with good runners he incurs much more risk than if all the runners are about equally good. The poor runner will already be unduly tired by the speed of the initial climb, and therefore runs increased danger of fatigue and fall on the descent. Most accidents happen in fact to people who have set themselves too difficult a task and have undertaken tours of which they were not yet capable.

That good runners incur a very small risk is also ıe experience of our Swiss ski-running competitions hich I have medically inspected since 1920, during hich time I have seen at least 1000 long-distance ›mpetitors and some 1300 military patrols. Among ıem not a single severe accident occurred in spite the severe demands made on them and the unfavour›le conditions of snow and course. This is also ›nfirmed from the sporting side by Erb as ski-ing acher and instructor of a Swiss mountain brigade.

The practical deduction from all this is that we ıould so develop our ski-ing technique that we can ›nture even on long and difficult tours with diminished sk of danger. The equipment must be carefully seen before every such tour. Difficult tours should ways be made with a guide, and due consideration ould be given to the experience of mountaineering, hich has in England especially such prominent lvocates. The risk of accident will then be brought ›wn to a very low level, as may be seen from the atistics of ski-instructors already mentioned, who ıly had seven accidents in 6000 lessons, say 1·2 per ›nt., an almost negligible figure. Of these, six ›curred to poor runners, only one to a good runner. n tours in the same period 1900 persons were ›nducted, of whom nine suffered injury—one of ıese was a good runner, one a middling runner, and ıe remainder were poor runners. These figures ustrate clearly the conditions which lead to increased sk on the part of poor runners, but they show also ıat reasonably conducted ski-ing carries with it no rticularly high risk of injury. Anyone who is raid of a possible accident is no sportsman; anyone who provokes an accident by negligence is also at heart no sportsman.

The figures given above are valid for Arosa as a type of Swiss winter-sport resort. They are naturally not to be transferred without adjustment to other climates and other types of hilly country, but must be assessed elsewhere with due regard to local conditions. It would be very desirable to obtain without delay from other resorts similar collections of the largest possible material. For the Swiss high alps the acts may be considered closed.

Clinical and Laboratory Notes.

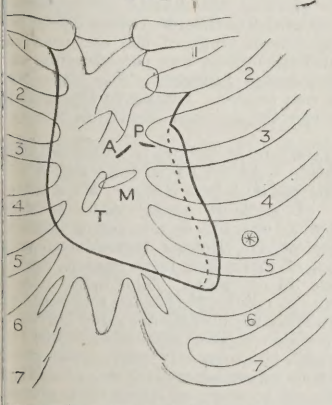
NOTE ON METHOD OF RECORDING THE PHYSICAL SIGNS IN RHEUMATIC CARDITIS.

By M. O. RAVEN, D.M. OXF., M.R.C.P. LOND.,

MEDICAL OFFICER TO ST. MARY'S HOME AND TO BISHOPSBOURNE AND OLD MANOR HOUSE SANATORIA, BROADSTAIRS.

IN the institutional treatment of pulmonary ıberculosis it has long been the custom to record ıe pulmonary physical signs by diagrammatic ıethods, whereby they can easily be understood by medical men. The method allows one medical man to appreciate the signs found by another, and also provides for a series of diagrammatic representations of those signs at regular intervals of time, so that at the end of the series a fairly accurate idea of their progress can be obtained.

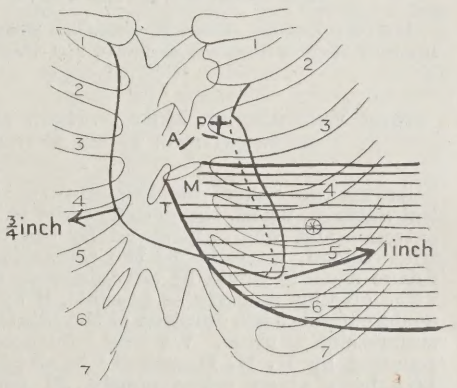
FIG. 1.



mpression of the rubber stamp on which the physical signs are recorded.

Rheumatic heart disease is likely to come more and more under institutional treatment during the next few years, and some similar diagrammatic method f recording cardiac physical signs will probably ecome desirable. While working in a small ard at St. Mary's Home, Broadstairs—a ward evoted mainly to treatment of rheumatic disease ı childhood—I became most dissatisfied with the methods I had of keeping a serial record of cardiac physical signs in any child, and I therefore adopted a diagrammatic method. Messrs. E. M. Richford, 40, Cheapside, London, E.C., constructed for me a rubber stamp the impression of which is shown in Fig. 1. This impression, adapted from a diagram in Cunningham's "Manual of Anatomy," enables me to record the physical signs given by the rheumatic heart from month to month, together with brief accompanying notes on special symptoms and signs, such as pallor, tonsillitis, or sinus arrhythmia.

FIG. 2.

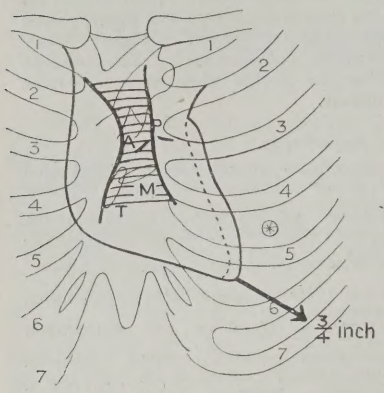


Mitral regurgitation; the murmur is conducted to the axilla. Apex-beat 1 inch displaced to the left and in the fifth intercostal space. Right border of heart ¾ inch dilated. Pulmonary second sound accentuated.

The three accompanying diagrams illustrate my method, which has saved me much time and uncertainty in my estimate of clinical progress. (Figs. 2, 3, and 4.) The left nipple and the right sternal margin being shown, it is a simple matter to indicate the the positions of the heart-borders by arrows with the number of inches of dilatation attached to them; the position of the apex-beat is similarly shown in the proper left intercostal space. Abnormal auscultatory signs may be mapped out, regurgitant murmurs, whether mitral or aortic, being horizontally shaded and obstructive bruits vertically shaded; the areas shaded correspond with the areas of audibility. An accentuated sound is marked by the sign +. Diastolic mitral murmurs—variations in which are of such

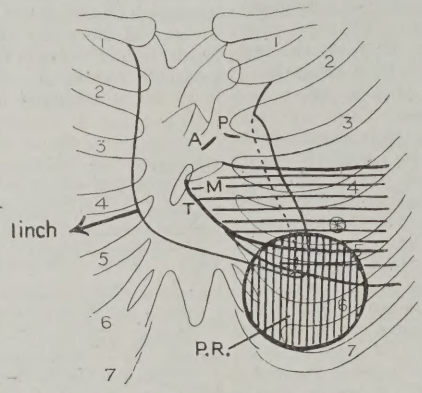
especial prognostic significance in relation to mitral stenosis in later life—vary so much in their time-relation and also with the posture of the patient (especially after exertion) that I append to the marking of the murmur letters that denote whether the murmur is heard early in diastole (E), in mid-diastole (M), or as a presystolic bruit (P), and whether heard at the area indicated in the left lateral position only after physical exertion. Finally, I include (Fig. 5) an example of notes summarising a periodical examination in a complex case.

FIG. 3.



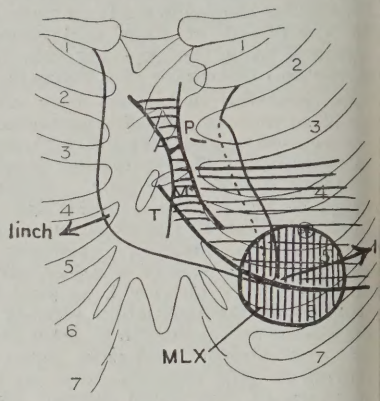
Aortic regurgitation; murmur conducted as shown. Apex-beat in sixth space (hypertrophy of left ventricle) and ¾ inch to left of nipple line.

FIG. 4.



Mitral regurgitation. Mitral obstruction. P.R. indicates a presystolic bruit heard in the supine position. Right border of heart 1 inch displaced to right of right sternal margin.

FIG. 5.



Summary of periodical examination in a complex case: No pallor; tonsils large and ragged; no chorea; evening temp. 98·4° F.; pulse 96; slight sinus arrhythmia; up for two hours daily.

NOTE ON THE USE OF INTRAVENOUS SODIUM BICARBONATE SOLUTION IN THE TREATMENT OF BLACKWATER FEVER.

BY W. ERNEST COOKE, F.R.C.S. IREL., D.P.H.,
MEDICAL SUPERINTENDENT, HOSPITAL FOR TROPICAL DISEASES, LONDON;
AND
HUGH WILLOUGHBY, M.R.C.S. ENG., D.T.M. & H.,
HOUSE PHYSICIAN TO THE HOSPITAL.

AFTER the case of blackwater fever[1] we reported last autumn, where the patient came into hospital in extremis and was only saved by the transfusion of whole blood, we came to the conclusion that in all future cases it would be advantageous to render the urine alkaline as early as possible, if by so doing we could cut short the duration of the attack and obviate suppression of urine. We were influenced by the case reported by H. M. Hanschell[2] in which the patient had been given intravenously 20 oz. of sodium bicarbonate solution (strength grs. 150 to the pint), within one hour of being seen by the doctor with the result that the impending suppression of urine was prevented, diuresis promoted, and the attack apparently curtailed. The work of S. L. Baker and E. C. Dodds[3] supports this method of treatment in all cases of hæmoglobinuria. They state that:—

"It (the treatment) should be such as will reduce the factors leading to precipitation of the pigment in the kidney tubules; these factors are seen to be acidity and salt concentration of the urine. Alkaline diuretics or transfusion of sodium bicarbonate solution as soon as possible should tend to minimise the hæmoglobin precipitation of the tubules."

We have recently had two cases of blackwater fever in which we were able to try this method. The histories are briefly as follows:—

CASE 1.—European male, aged 56, had been in Kenya Colony for 30 years and had had four previous attacks of blackwater fever, the first in 1900 and the last in 1919. He gave a history of frequent attacks of subtertian malaria in the past, but more recently had had no definite attacks of fever. He was an irregular quinine taker. The day before admission to the Hospital for Tropical Diseases he had felt "off colour." Suspecting himself to be suffering from an attack of malaria he took quinine grs. x. at 10 A.M. and grs. 5 at noon on the succeeding day (day of admission). After the second dose of quinine he passed dark-coloured urine, was slightly jaundiced, and perspired freely. Recognising the condition the patient sent for a doctor, who ordered his immediate removal to hospital. When he was admitted at 7 P.M. his temperature was 101° F., his pulse-rate 110, and his respiration-rate 20. A blood count was immediately taken and he was found to have 4,800,000 red cells, 6000 white cells, and a hæmoglobin percentage of 85. No parasites were seen, nor was there any evidence of corpuscular degeneration. His urine had a specific gravity of 1008, and a faintly acid reaction; it contained a quantity of albumin and scanty red amorphous casts, but no erythrocytes. The spectroscope showed the bands of oxyhæmoglobin. The patient complained of intense thirst, had a dry and coated tongue, and an icteric tinge of the conjunctivæ, face, limbs, and trunk, and his spleen was palpable one and a half inches below the costal margin. The liver was enlarged downwards and was tender. Owing to the prompt action of his medical adviser the general condition was fair on admission.

It was decided to give sodium bicarbonate solution intravenously as soon as possible. At 8.30 P.M. (one and a half hours after admission) the patient had a rigor, after which he was given 10 oz. of sodium bicarbonate solution followed immediately by 8 oz. of 5 per cent. glucose solution. Sleep then followed. Before transfusion with sodium bicarbonate 17 oz. of urine had been passed, and in the eight succeeding hours 36 oz. more. The urine passed after transfusion was deeper in colour, this being undoubtedly due to the rigor and hæmolysis which had occurred earlier in the evening. Twenty-four hours later, the urine being still very dark in colour although the quantity passed was good, intravenous transfusion was repeated with 7 oz. of sodium bicarbonate solution followed by 4 oz. of 5 per cent. glucose solution. The total urine passed in the 24 hours was 56 oz. followed by a further 42 oz. during the next night. After the second transfusion the urine started to clear, although the patient complained of some pain and irritability on micturition, and within 46 hours of the onset the appearance of the urine had become perfectly normal. After the first day the temperature fell to normal and no further pyrexia occurred. Icterus persisted for four days in all, and on the fifth day the spleen was no longer palpable. In spite of the severity of this, the patient's fifth attack, he made an uninterrupted

[1] THE LANCET, 1928, ii., 645.
[2] Trans. Roy. Soc. Trop. Med. and Hyg., 1926, xix., 488.
[3] Brit. Jour. Exper. Path., 1925, vi., 247.

recovery, and his red cells never fell below 4,260,000 per c.mm. with a hæmoglobin percentage of 85. No malarial parasites were ever seen in the blood films during the disease, but, following our routine, the patient was given treatment with plasmoquine compound when he had fully recovered from the attack of blackwater fever. As is usual in these cases, the patient was kept on a fluid diet, with grs. 5 of sodium bicarbonate added to each feed.

CASE 2.—European male aged 28, had returned five weeks previously from Nigeria and was an irregular quinine taker. Feeling feverish and having vomiting, pain in the loins, enlarged spleen, and diarrhœa, he saw a consultant, who diagnosed the case as malaria and sent him to the Hospital for Tropical Diseases. He was admitted that evening, and on examination was markedly icteric, had an enlarged spleen palpable one inch below the costal margin, pain and tenderness over the lumbar region, and a slight rise of temperature. His blood count showed 4,800,000 red cells; hæmoglobin 85 per cent., and 6000 white cells. Scanty subtertian rings were present in the film, but no corpuscular degeneration was observed, and the urine was normal. The condition being recognised as a pre-blackwater stage, the patient was kept strictly to bed and put on a fluid diet with sodium bicarbonate in all feeds.

Next day his condition was greatly improved and plasmoquine compound, one tablet twice daily, was ordered. On the following day, instead of the two grains of quinine contained in the compound plasmoquine tablets, he was given one dose at 6 A.M. of quinine hydrochloride, grs. 5. His general condition had so much improved that this increase appeared to be warranted. At 10 A.M., however, he passed urine dark in colour and at 12.30 P.M. definite blackwater supervened. This urine had a specific gravity of 1012, an acid reaction, and contained much albumin. Scanty red amorphous casts were present. In a blood film taken at this time no parasites and no corpuscular degenerations were seen. The urine showed the bands of oxyhæmoglobin in the spectroscope. As in the previous case, 10 oz. of sodium bicarbonate solution, followed by 4 oz. of 5 per cent. glucose solution, were given intravenously at 4.30 P.M. Immediately after the transfusion the patient had a rigor with a rise of temperature to 105·4° F., but this had fallen to 102° F. by 10 P.M. Again, as in Case 1, the urine subsequently passed was much deeper in colour, and reached its deepest tint by midnight when it was, however, strongly alkaline in reaction. As the patient was vomiting persistently rectal salines with glucose were given six-hourly, and tinct. iodi. ℥ i. doses by mouth and gr. 1/6 of morphia hypodermically were also given.

Next day the temperature was still 100°–102° F. and vomiting persisted. The kidneys were, however, functioning well and 69 oz. of urine were passed in the 24 hours. On the following day the temperature fell to normal at noon, jaundice was less marked, vomiting had ceased since 2 A.M., and at 4 P.M. the urine passed was quite clear, exactly 51½ hours after the onset of the blackwater. Plasmoquine compound was resumed later in small doses and the patient made an uninterrupted recovery.

The blood count in this case fell as low as 2,100,000 red cells with a hæmoglobin percentage of 50 at the time of cessation of the blackwater, but rapidly regenerated and was normal three weeks later. The spleen was no longer palpable three days after the attack began.

Comments.

1. Both cases were negative to tests for paroxysmal hæmoglobinuria.

2. As both patients were of continental nationality and accustomed to alcohol, champagne was given daily in small quantities without adverse effects.

3. Case 1 had two intravenous transfusions, and even though he was an older man and had had in addition the shaking and disturbance of an ambulance journey at the height of the attack, his urine cleared more rapidly than did that of Case 2, and he did not have such severe hæmolysis. In his case the second transfusion, indicated on account of the subnormal temperature and lack of appreciable improvement in the urine, may have been the determining factor in obviating the persistence of the hæmolytic process. In Case 2 the urine took longer to clear and there was a more severe hæmolysis, but only one transfusion was given. The second transfusion was withheld, as the temperature was approaching normal and rectal salines were being well retained.

4. Both cases gave a negative result to the Wassermann test, and there were no signs of any intercurrent disease.

5. Judging from the results of these two cases it appears that immediate transfusion with sodium bicarbonate solution is indicated in all cases of blackwater fever to curtail the duration of the attack, to prevent blockage of the kidney tubules, and to avoid suppression of urine.

6. More than one transfusion may be needed and should be given when there is no appreciable improvement within the first 24 hours. The need for further transfusions should be judged by the progress of the case.

7. Although rigors and further hæmolyses may occur after transfusion the effect on the urinary system fully justifies the measure, but should signs of anoxæmia appear blood transfusion must be employed instead, and this must be from a donor who is not taking quinine.

In conclusion, our thanks are due to Dr. P. H. Manson-Bahr for permission to publish these cases, and to Dr. H. B. Newham, Dr. P. H. Martin, and Mr. F. W. Foster for carrying out the pathological investigations.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF WAR AND SURGERY.

AT a meeting of these two Sections on Feb. 6th, Sir HOLBURT WARING being in the chair, Group-Captain H. V. WELLS opened a discussion on the importance of

EARLY DIAGNOSIS IN TREATING SPINAL INJURIES.

The diagnosis of serious injury to the spinal column following an aeroplane crash, he said, was a matter of much importance, not only in the Air Force, but to the medical profession generally, especially remembering the increase taking place in civilian flying. The chief difficulty naturally arose in connexion with cases in which obvious signs and symptoms were lacking, where fracture of a vertebral body was not immediately followed by apparent grave involvement of cord or nerves. In so-called "missed cases" it was found that weeks, even months, after a crash, spinal curvature or definite neuritis supervened, and a skiagram taken at this remote date showed what the injury was. At the time of the mishap perhaps all that had been reported was a bruising or a straining of the muscles of the back, the only attention given immediately after the accident having been a few days in bed and some massage. After weeks back at work, the man perhaps reported shooting pains in the back, or an inability to straighten himself painlessly.

He divided these fractures into "upper" and "lower." The former were in the upper flexible part of the spinal column, the latter in the more rigid lower region. Fractures in the upper region were brought about by the spine being forcibly bent upon itself; the head was forced forwards upon the curved upper spine, and the maximum force of compression was most often borne by the second or third dorsal vertebra. The fact of the pilot being secured in the plane by a belt was not now thought to contribute to the injury, as it was sufficiently loose to allow of "play," and was only intended to prevent the man from falling out. Fractures in the lower region were, he said, produced by the weight of head and chest being borne by the lumbar spine at the moment of impact, the power of the impulse being reinforced by the rebound being transmitted through the lower limbs. During the apprehension as to what was going to happen, the legs were braced against the rudder-bar, and so the force of impact at the moment of the accident was concentrated on the lumbar spine. The special type of fracture being discussed was the compression or crush fracture, one involving only the vertebral body. The cancellous tissue suffered

crushing, and apparently the spinal column sprang back after the blow.

The patient merely complained of a stiffness or a pain in the back, and there appeared to be no displacement in the spinal line, the reflexes being normal. Strain of the back muscles was usually diagnosed by the medical officer, and the treatment was directed accordingly. Perhaps examination by X rays was not deemed necessary. Only later, when rarefaction had set in, a yielding of the fractured vertebræ was the extent of the injury disclosed. Obviously the spine should be subjected to X rays in every case of accident to the spine, though admittedly at any early stage examination of such a skiagram it might reveal nothing abnormal. Therefore, reliance must be placed on the history and the presence or absence of pain. The medical officer should ascertain the angle and probable speed at which the craft struck the ground; if the propeller and leading edges of the plane were much damaged, it could be assumed that there was enough force of impact to damage the vertebral column. It was not always safe to rely on the presence of pain in the diagnosis. Many patients who had had flying accidents had had definite pain in the lumbar region for varying periods, with a site of maximum tenderness over a particular vertebra. All those recovered without residual symptoms. It was considered that they had had compression without fracture.

It had been suggested, Group-Captain Wells said, that severe compression might cause such a bone lesion that absorption of bony tissue ensued after a period, and he asked whether there were any means of detecting this. Could such a danger be avoided by giving calcium vitamins, or carrying out a course of endocrine therapy? The X rays seemed only to be definitely useful in these cases some time after the injury. The safe policy seemed to be to regard and treat all cases of pain in the back after injury as potential fractures, though if this were made a rule there would be a good deal of unnecessary loss of manpower. When there were obvious injuries to head or other parts after an accident, there was a tendency to forget the chance of serious damage having occurred to the spine.

The Surgical Aspect.

Sir PERCY SARGENT said that the spinal cases he had seen since the war had been due to two common types of cause. The first were those occurring in colliery accidents, the second those due to a fall in the hunting-field. In the first of these classes, a mass of coal fell on the back of the miner while he was in the stooping posture. In the accidents while hunting the mechanism was not always apparent, but hyperflexion of the spine often played the chief part. When the force was extreme, a common dislocation-fracture ensued. It was not his purpose now to speak of gross injuries. A common type (which he depicted on the screen) was one in which one of the bodies was broken off, and usually another piece was pushed back into the spinal canal, causing an angular deformity. In the case illustrated, though the patient lived for some time afterwards, no change had apparently occurred in the architecture of the cancellous tissue of the bodies. In most cases of crush-fracture there must be something more than mere damage to bodies of vertebræ. The cauda equina might be damaged without any obvious bony injury, and without any symptoms occurring at the time; yet the foundations might be laid for traumatic lesions of cord and nerve-roots.

Referring to cases in which no conspicuous damage was done, but in which patients might suffer considerably at a later date, Sir Percy emphasised the need for a special effort to make a firm diagnosis at an early stage. In cases of apparently minor injury to the spine it was advisable to impose a probationary period, not only for rest but also for observation and treatment. A systematic neurological examination should be made and the results recorded; this should be repeated from time to time in case physical signs should come on later. Lateral as well as antero-posterior skiagrams should be taken in every case. In a case shown on the screen the usual antero-posterior skiagram showed nothing abnormal, but a lateral picture revealed a gross lesion with telescoping of the bodies. Attention should be directed to the condition of ligaments and muscles, because of the pains and the possible onset of bony deformity later. A spine which appeared radiographically to be normal immediately after the accident might afterwards show atrophy and collapse of one or more vertebral bodies, as after a crush-fracture. He deprecated the use of the terms "Kümmell's disease" and "post-traumatic spondylitis," as these implied disease or inflammation, neither of which was present. In the condition described by H. Kümmell, of Hamburg, the probable explanation was a mechanical one, excessive pressure being brought to bear on the vertebral bodies, the posterior ligaments and muscles having been so damaged that they did not take their due share of the burden. This condition was likely to be progressive unless treatment was adopted with the aim of supporting the spine from behind; a spinal brace should be used, the muscles being exercised meanwhile—an essential point. Massage seemed to have no other effect on the muscles than improving their nutrition; the effective treatment of muscles consisted in the induction of rhythmical graduated contractions by Morton Smart's or some similar apparatus. The results so obtained were extraordinarily good.

In some cases symptoms of pressure on the cord appeared months or even years after injury of apparent unimportance. To these Sir Victor Horsley applied the name meningitis circumscripta serosa. A coal-miner who had been crushed came to hospital 16 years later. He then had numbness and weakness of the legs, and tingling sensations. Knee- and ankle-jerks were absent. There was an impairment of sphincter control, not objective sensory loss. An angular deformity was found in the lumbar spine, and rarefaction of the bodies of the lumbar vertebræ. Protein content was 2 per cent. Laminectomy was performed, and the cauda equina was found angulated over a prominence. The patient left the hospital well after operation. It was a case of meningitis circumscripta, undoubtedly following injury.

In dealing with victims of aeroplane accidents who showed no sign of spinal injury, it should be remembered that though temporary incapacity in respect of muscles and ligaments was common, more serious latent effects, such as secondary spinal cord symptoms, were comparatively rare. Prolonged incapacity from pain and minor lesions could be prevented by appropriate treatment of damaged muscles, combined with such rest to the parts as might be indicated in any given case. Patients who showed even slight and transient signs of cord injury must be treated with great respect, in view of the possible development of more serious symptoms later.

The psychological aspect of these cases, Sir Percy concluded, was also of importance; how far that affected men in the R.A.F., Group-Captain Wells could perhaps say. In his own experience there was a wide psychological difference between cases occurring in the mine and those taking place in the hunting field. Victims of the hunt had the one ambition to get back to their ordinary life as quickly as possible, whereas in the miner's case the question of compensation loomed large.

Discussion.

Air Vice-Marshal D. MUNRO said the accidents in the Royal Air Force corresponded more nearly to those in the hunting-field than to those in the mines. No claims for compensation had been made in the Service on account of spinal injuries, nor had there been any cases in which there was even a suspicion that psychology had anything to do with it. He particularly asked what was the pathology of cases in which symptoms of injury were so long delayed and why the indications remained so long latent

Did rarefaction gradually take place on account of continued pressure on bone which had been somewhat damaged?

Surg. Vice-Admiral A. GASKELL said that in the Navy both kinds of injury to the spine which Sir Percy Sargent mentioned were met with; men had sacks of coal fall on their back while stooping, and in that branch of the service were many men who were fond of horses and seized every opportunity to hunt. He agreed that the great difficulty when a man had sustained a crash was to know what damage had actually been done to the spinal column. Prof. Hey Groves had recently stressed the great importance of radiograms in different directions in cases of injury. When a softening or rarefaction of bones took place, Nature's lines were disturbed, and so the vertebral column assumed a different angle, leading in course of time to pain and stiffness.

Major J. M. WEDDELL pointed out that sometimes the casual accident was only a minor one, nothing like so great as in an aeroplane crash, and this made the difficulty of diagnosis the greater. Often there was a site of localised hyperæsthesia, and a radiogram would often show a wedge-shaped or deformed vertebra, but not in early stages. In one case only after three careful radiograms was a fissure-fracture revealed.

Dr. BERTRAM SHIRES discussed the radiological aspect of the question. He said that in some of the cases if a skiagram were taken in both aspects immediately after the injury evidence of damage might be revealed, but often a radiogram was not called for until a considerable time afterwards. If this course was followed at a very early stage, few cases would in future be missed.

Dr. MORTON SMART remarked that he did not think anyone was able to say how much the posture of the body was dependent on the bony part of the spine, and how much on the muscular and ligamentous part. He had been much impressed by the importance of the muscle factor in keeping the body erect. When injury to the spine took place, the muscles—the first line of defence—must give way, and so in fractures of the spine there was injury to muscles, probably also to ligaments; and in many cases keeping in bed brought about almost complete recovery. In most cases, however, soon after getting about again, the patient had a variety of pains in the back, and some pains referred to other parts of the body. This, he considered, was because the muscles, in the course of their repair, became adherent to neighbouring tissues. One result of accident to muscles was that they became quite atonic, and at that stage the efforts of the nervous system to produce contraction were wasted.

Mr. CECIL WAKELEY said that most of these cases in civilian life were due to pressure fractures; fissuring might occur on only one side. An X ray picture taken in the extended posture would often show the fissure. If it was not very definite, another skiagram should be taken from the other side.

Mr. PATERSON ROSS said it was important to ascertain what produced the atrophy; he thought it might be centred in the question of pain. The spine consisted of a series of joints, and a painful joint always resulted in atrophy of surrounding muscles because of the pain, and this atrophy probably led to the wedge-shaped deformity.

Surg.-Commander J. L. PRISTON, dealing with the psychological aspect, suggested that people meeting with accidents in the hunting-field generally had grit, vulgarly called "guts," and were determined to do their best to get back to ordinary life; while in the case of workers in mines and elsewhere the compensation factor was always present to mitigate the eagerness for recovery until the monetary matter had been settled.

The CHAIRMAN suggested that in some of the cases under discussion an important factor was the presence of torn ligaments.

Reply.

Sir PERCY SARGENT said the reason these bones collapsed at a later date was unknown. In some cases examined post mortem, nothing was found but a crumpling of the cancellous tissue of the bone, with hæmorrhage into that tissue. That, however, did not explain the tardy symptoms. He agreed with Dr. Smart that immediately after a muscle had received a severe injury it was actually paralysed.

SECTION OF TROPICAL DISEASES.

A MEETING of this Section was held on Feb. 7th to discuss

MONKEYS AND HUMAN DISEASE.

The chair was taken by Dr. J. B. CHRISTOPHERSON, the President, and the zoological relationships of the primates were first reviewed by Mr. R. I. POCOCK, who contrasted the hands, feet, and habits of the cynomorpha—or monkeys—which were essentially quadripedal on the ground and expertly arboreal, and the anthropomorpha—or apes—which had relatively very long arms and never rested the palm of the hand on the ground. Young apes, he said, could run very well on the legs alone, putting the weight on the heel, like man and unlike the monkeys, which never rested on the heel. Monkeys climbed on the tops of branches while gibbons swung on their hands beneath. The apes seemed to have learned to climb secondarily. The greatest difference of all between man and ape was in the foot; man's foot was unique, and never at any stage of its development showed the divagation of the great toe found in apes and monkeys. Perhaps the appearance of man had driven the apes back to the trees.

Mr. R. LOVELL dealt with

Bacterial Diseases of Monkeys.

He said that no authenticated case of bacterial disease in the natural wild state was on record. Diseases occurring spontaneously in captivity were (*a*) respiratory, (*b*) digestive, and (*c*) tuberculosis and other infections. Epidemics of pneumonia had been recorded, and pneumococci, types 2 and 4, hæmolytic streptococci, and the influenza bacillus had been isolated. Vaccine treatment had been successful on one occasion in stopping the spread of infection, and overcrowding had been adduced as an ætiological factor. An epidemic of colitis amongst baboons had been due to *Bacillus aertrycke* Mutton. Morgan's No. 1 bacillus and Flexner's bacillus had also been isolated from monkeys of various species suffering from gastro-intestinal symptoms. There seemed no doubt that Morgan's bacillus could be pathogenic in monkeys, though the part it played in summer diarrhœa of children was doubtful. An unidentified non-motile Gram-negative bacterium, producing acid in dextrose, maltose, and mannite but not in lactose or sucrose, had been isolated from a number of monkeys showing post-mortem intestinal infection; this organism was allied to the dysentery group. Tuberculosis was a common cause of death among captive monkeys; human and bovine types were equally virulent but death was almost always due to the former. Two Barbary apes had died from infection by a member of the pasteurella group and one chimpanzee from a staphylococcus septicæmia. Experimentally, monkeys had been used for many organisms affecting man—e.g., Malta and yellow fevers, to both of which they were very susceptible. Pneumonia could be caused by insufflation of pneumococci and the influenza bacillus, and meningitis and leprosy had also been transferred to them.

Mr. E. HINDLE'S paper on

Virus Diseases of Monkeys.

was read in his absence by the Secretary. It pointed out what favourable subjects monkeys were for experiments with filterable viruses. Yet monkeys in the wild state did not seem to be susceptible to these organisms, except rabies. Nevertheless, yellow fever epidemics seemed to be preceded by the deaths of large numbers of monkeys. Monkeys so rarely came in contact with man that their importance in

disseminating disease must be very slight. In India, however, large numbers of semi-domesticated macaques lived in close contact and might serve as reservoirs of rabies. The experimental study of yellow fever had depended almost entirely on the discovery that the Asiatic species, particularly *Macacus rhesus*, were susceptible, although local monkeys had complete natural immunity. There seemed no correlation between virulence of a strain in man and in monkeys; indeed, there seemed some reason for thinking a mild strain in man might be most dangerous to monkeys and vice versa. Nevertheless, the virus retained its virulence for man even after repeated passage. The virus could pass through the unbroken skin of the animal. The only certain way of recognising the disease in them was by the post-mortem appearances, which were identical with those in man. The virus did not, however, disappear from the blood and internal organs after a few days of infection as it did in man.

The vaccination discovered through work on monkeys gave a high degree of success in animals and had been used successfully in the Rio de Janeiro outbreak.[1] It seemed likely to prove a satisfactory form of protection.

Poliomyelitis had so far been reproduced in monkeys only, and subdural injections of suspensions of the spinal cord and cortex would carry it on, with increasing virulence until 0·001 c.cm. of a 5 per cent. suspension would kill every animal injected. The human disease was closely simulated, both clinically and post mortem, and experimental work depended on this. Measles had been produced in monkeys by intratracheal insufflations of filtered nasopharyngeal washes from patients, and transmitted to other monkeys and immunity produced thereby. Other virus diseases, such as small-pox, trachoma, and Rocky Mountain fever, found good hosts in monkeys but usually would infect other animals as well. Monkeys were, however, preferable because the course of their disease more closely resembled that in man.

Dr. T. W. CAMERON dealt with

Protozoal and Helminthic Diseases,

embodying a contribution on protozoa from Dr. J. G. THOMSON, who said that comparative study showed that the species in men and monkeys were in many cases identical. Histolytica-like amœbæ had been found in monkeys but were seldom associated with acute dysentery, although they seemed exactly similar to the *Amœba histolytica* of man. Several genera of flagellates were found both in men and monkeys; they were morphologically similar in the two hosts and probably identical. Man might be infected with *Balantidium coli* from pigs, and monkeys could be infected from the pig or man. There was no reason to doubt that monkeys were naturally infected with human trypanosomes, which could readily be subinoculated in them. The presence of malarial parasites in several species had been recorded, but there had only been one positive infection with *Plasmodium vivax* by the injection of human malarial blood. There was no proof that the organisms were identical or that apes could have human malaria.

Turning to his own paper, Dr. Cameron said that the dozen common and important helminths in man belonged either to the flat worms or the round worms. None of the important trematodes of man, except the blood flukes, had been found naturally in monkeys. All the species had been passed to monkeys experimentally and *Schistosoma mansoni* had recently been found naturally among West African green monkeys in St. Kitts. Apart from this organism the natural flukes of monkeys were more closely related to those of bats and ruminants than of man. None of the typical cestodes of man had been reported from primates, but the typical simian genus bertiella had been found occasionally in man. The most important larval cestode accidentally harboured by man was the hydatid, which was also found in monkeys. In man about 75 per cent. of the primary infections were hepatic, but in monkeys 50 per cent. were pulmonary. This distribution was also characteristic of carnivores, rodents, and cattle, and was due to large hepatic vessels, which passed the parasite through the liver. The characteristic human nematodes were ascaris, enterobius, trichocephalus, œsophagostomum, physaloptera, trichinella, hookworms, guineaworms, and filariæ. *Ascaris lumbricoides* was a very rare accidental simian parasite, but monkeys harboured various species of enterobius, though *E. vermicularis* was peculiar to men. *Trichocephalus trichuris*, the most widespread human parasite, was also the most universal monkey-worm, although present in small numbers. Ankylostoma was not found in monkeys, but necator was. Monkey filarias were a distinct genus of which the nearest human relation was *F. perstans*. There were several common monkey œsophagostoma. *Physaloptera caucasica*, a common baboon parasite, had been fairly often found in man. Trichinella could be conveyed to monkeys but did not reach them naturally. Apart from the whipworms, the commonest simian nematodes belonged to the genus subulura, which never occurred in man. The monkey was a definite reservoir host of schistosomes and possibly also of physaloptera and trichocephalus. It was extremely probable that African monkeys harboured *S. mansoni* and *S. hæmatobium*, and that physaloptera had some intermediate host.

Lice and their Bearing on Phylogeny.

Dr. V. B. WIGGLESWORTH said that bird lice had been shown to have a racial distribution. From a study of their parasites it was possible to say that gulls were merely plovers which had changed their form and that flamingoes were just comic ducks masquerading on stilts. The sucking lice peculiar to the mammalia were less abundant. The first group consisted of a single species found only on elephants, both in Africa and Asia. The second group—hæmatopinnidæ—included nearly all the lice of mammals, while the third—pediculidæ—was confined to the primates. Pediculus was found only on man, the chimpanzee and the two gibbons, and also on the spider-monkey of South America. This monkey had been shown to possess characteristics of hair and blood very closely allied to those of the anthropoids and man. Perhaps it was in virtue of these that pediculus had passed from an anthropoid to one special monkey at a period that must have been very remote, as several species had since been differentiated. The crab-louse, long believed to be peculiar to man, had been found by Ewing on the gorilla.

Colonel A. E. HAMERTON described the specimens which he had brought from the Zoological Society's prosectorium to illustrate the morbid histology of monkeys. These included a number of cases of generalised tuberculosis, and a case of mixed mycosis and tuberculosis in a wanderoo macaque. He remarked on the fact that monkeys found riddled with tuberculosis post mortem often showed no symptoms up to the day of their death. Another specimen showed a placenta prævia in a rhesus macaque which had died of hæmorrhage at the end of the first stage of labour. Others showed sarcoma of the lung in an orang-utan with metastases in the liver, spleen, and left kidney; a sarcoma of the right kidney with extensive spread in a capuchin; mitral vegetations in a Pluto cercopitheque—an uncommon condition; intussusception in a macaque, and hæmorrhagic ulceration of the bowel, due to *Bacillus aertrycke*, in a baboon.

Discussion.

Dr. H. H. SCOTT described the *B. aertrycke* outbreak on the monkey hill at the Zoo, due to a carrier and temporary blockage of the water-supply, and a case suggesting that pneumonia in a green cercopitheque had begun as a primary blood disease, settling secondarily in the lung.

Dr. A. BALFOUR recounted his experience in Trinidad, suggesting that monkeys might act as a natural reservoir for yellow fever.

[1] THE LANCET, Jan. 26th, p. 183.

Dr. G. C. LOW did not see how the red howler monkey could have anything to do with yellow fever epidemics, as it never came in contact with human beings. Yellow fever was typically a seaport disease and occurred where there were no monkeys.

Dr. KINGSTON BARTON and Colonel BROUGHTON ALCOCK asked some questions, to which Dr. LOVELL, Dr. SCOTT, and Colonel HAMERTON replied.

SECTION OF UROLOGY.

AT a meeting of this Section on Jan. 24th, with Mr. SWIFT JOLY, the President, in the chair, a paper on

TRAUMATIC RUPTURE OF THE URETHRA

was read by Sir WILLIAM WHEELER. The contribution, was founded, he said, upon six cases encountered during the years 1921–28. The condition was a rare one; only 41 fresh cases of it had been admitted to the wards of the London Hospital in the ten years 1909–19, and only 20 cases had been admitted to the Liverpool Royal Infirmary during the past decade. Rupture was far more common in the bulbous portion of the urethra, well in front of the triangular ligament, and it was known that if the membranous segment was severed it was exceptional for a tight stricture to develop in the process of healing. It had been stated that in France the accident usually occurred in young adult men, but the speaker did not think this was so in all countries; in his own six cases the average age was 42, while in Mr. Frank Kidd's 57 cases it was 33 years. Sometimes extravasation from the injury was seen in the anal region, the ischio-rectal fossæ, and the thighs. Anatomical limits were more commonly overrun in non-traumatic rupture occurring behind old infected strictures. In the first case of Sir William's series the urethra was torn off near the neck of the bladder, above the triangular ligament, and before operation the outstanding feature was a spread of urine and blood into the perinæum, scrotum, penis, and the front of the abdomen, in a way characteristic of rupture in the region of the bulb.

Diagnosis.

When the urethra ruptured well in front of the triangular ligament a perineal hæmatoma nearly always followed; blood trickled from the meatus almost immediately, and though the patient had an intense desire to pass water he could not do so. The local pain was severe. Extravasation of urine was prevented by reflex spasm of the compressor urethræ muscle until hours had elapsed. But for this saving spasm the mortality from early extravasation of urine and infection would be much higher. Often the amount of bleeding from the meatus after the accident was in inverse proportion to the urethral damage; after only partial division the hæmorrhage was likely to be more profuse and continuous than it was after complete rupture, for in the latter event hæmostasis was favoured by retraction of the part. Large hæmatomas might be found even when there had been no rupture if the corpus spongiosum was seriously damaged but the mucous membrane did not yield. Also severe traumatic stricture might follow injury without rupture. If the pelvis was broken the rupture was more likely to take place above the triangular ligament, in the region of the apex of the prostate. But it might be between the bladder and the bulb. The surgeon should always have in mind the possibility of a ruptured bladder above or below the reflection of the peritoneum. Because a ruptured bladder was empty it could never be palpated. A catheter could be passed freely through the urethra, but only small quantities of blood-stained urine came away. The extent of injury would be found at operation to be greater than had been anticipated judging by the signs and symptoms immediately after the accident; and this fact was a strong reason for operating in every case. A black patch on the glans penis indicated that probably the whole of the corpus spongiosum was infiltrated with urine. When there was extravasation in traumatic cases the absence of pre-existing infection (present in old-standing stricture cases) gave a relatively better prognosis, especially as the victims of the accident were usually in good health when it occurred. If operation was delayed, and the patient did not die, the parts became riddled with sinuses and urinary fistulæ—a very grave condition. Associated pelvic fracture should be treated.

Treatment and Results.

Sir William Wheeler laid stress on the importance of a uniform method of early treatment in these cases. One of his six patients died ten days after operation from pneumonia. This patient, whose age was 27, was operated on at an early stage, and there was no fractured pelvis or other complication. His rupture was in the region of the bulb. The other five patients in the series reported themselves cured after periods ranging from seven years to five months. Operation must not be undertaken hurriedly; good results largely depended on complete hæmostasis and asepsis. A hypodermic injection of morphia was given, and the distended bladder was, if necessary, emptied by suprapubic puncture before removing the patient to hospital. In describing his operative technique Sir William pointed out that when the rupture of the urethra was intrapelvic, the pubo-prostatic ligaments were torn and the bladder became displaced backwards. In such cases the retained catheter was necessary. The literature of the subject, he said, disclosed a general consensus in favour of immediate suprapubic cystotomy in fresh cases of ruptured urethra. The proximal end of the urethra —notoriously difficult to find—could be hit upon by retrograde catheterisation. By employing a retention catheter for about a fortnight and avoiding perineal drainage, four advantages were claimed: the patient was much more comfortable and nursing was simplified; there was a minimum of scar formation in the perineum; subsequent instrumentation was simplified; and convalescence was hastened.

Discussion.

Mr. RALPH THOMPSON said that in a long series of cases at Guy's Hospital the deaths following venereal stricture were 48, and following traumatic stricture two. In about one-third of the cases of fractured pelvis the urethra could be expected to be damaged. In most of the cases of ruptured urethra which came to the genito-urinary department at Guy's nothing seemed to have been done for the patients; no suprapubic cystotomy was carried out, nor any effort made to unite the ends of the ruptured urethra. The profession at large should be told of the importance of operating to deal with the urethra as soon after the accident as possible. The urethra might be only partially ruptured.

Mr. FRANK KIDD hailed with satisfaction this insistence by a distinguished general surgeon on the necessity for paying attention to this subject, and reminded the meeting of his analysis, in 1921, of a series of 57 cases at the London Hospital, showing how seldom the injury occurred. That 24 out of 25 of his patients remained alive showed that the accident was not so serious from the standpoint of life as many supposed. As a result of examining many cases he had arrived at the conclusion that the real cause of stricture formation was a pulping of the tissues. He did not think the use of a catheter made any difference to the occurrence of stricture. It was quite simple in these cases to make a small incision into the bladder, under an anæsthetic, straight away; then retrograde catheterisation could be carried out. Bad stricture cases which were causing trouble did very well after internal urethrotomy.

Mr. FOWLER WARD said he thought the end-results largely depended on the age and weight of the person and the stage the condition had reached by the time the surgeon was called in. In children he usually found that the injury was not severe, and under suitable treatment healing was prompt. When a

heavy man fell astride anything the injury to the urethra was generally very severe, and the case was not seen by the urological surgeon until the third or fourth day afterwards, the statement being that the patient had not passed water for a day or two. The tissues might have sloughed, and if so there was no chance of immobilising the ends of the ureter and bringing them together. What he had aimed at in several cases was passing a catheter through the penile urethra, and, if this was not possible, doing suprapubic cystotomy and retrograde catheterisation. He always preferred the use of silver catheters to rubber ones, as the latter occasionally became very objectionable.

Mr. WINSBURY WHITE described a case of fracture of the pelvis involving partial rupture of the urethra. In a run-over accident seven years ago the boy had his symphysis pubis separated about an inch, and there was considerable extravasation of blood in the perineum and external genitals, as well as in the upper part of the right thigh. No sign now remained of extravasation of urine, and he could pass urine freely.

Mr. CYRIL NITCH said that in two of three cases he had seen in children there was severe injury to the urethra and also associated fracture of the pelvis and crushing of the membranous urethra. Much scar tissue formed in consequence. He agreed with Sir William Wheeler that the best —indeed the only—line of treatment of these cases was to drain the bladder and suture the urethra.

Mr. HUGH LETT said that years ago Mr. Reginald Harrison pointed out that, where there was a leakage of urine, dense fibrous tissue was always met with. There was every reason for opening up the bladder in the first place in these cases and doing suprapubic drainage. He also dwelt on the advantage of retrograde catheterisation.

Mr. G. E. NELIGAN also emphasised the importance of suprapubic drainage of the bladder in these cases, followed by the tying-in of a catheter. In the type in which a person who had been run over sustained a fractured pelvis, and an injury between the prostatic and membranous urethra, there was often difficulty in getting the ends of the urethra together. He described his own modus operandi in these cases.

THE PRESIDENT said that four of the seven patients with this accident whom he clearly remembered were under the age of 20. Rupture of the urethra could follow a trifling accident. When the posterior urethra had been ruptured it was sometimes very difficult to decide what should be done, especially when the pelvis was fractured at the same time. But suprapubic cystotomy must be the first step.

Sir WILLIAM WHEELER, in reply, emphasised again the necessity of not hurrying the undertaking of the operation in these cases. If the bladder was dilated it was best to aspirate it. He did not use crutches in doing these operations; he found it better to give one leg of the patient each to an assistant, so that tension could be transferred at a moment's notice.

DONATIONS AND BEQUESTS.—The late Mr. Charles G. Arbuthnot, of Eaton-square and Knowle, Cranleigh, Surrey, left, among other bequests, £5000 to the Grosvenor Hospital for Women, and £1000 each to St. Andrew's Convalescent Hospital, Clewer, St. Andrew's Convalescent Hospital, Folkestone, and the Cancer Hospital, Fulham-road. —Mr. Alfred Charles Bunting, of Woodlawn, Uttoxeter, Staffs, left £500 to the Uttoxeter Nursing Association, £100 each to the North Staffordshire Infirmary and the Derbyshire Royal Infirmary, and, after other bequests, the residue of his property to his wife for life, with remainder as to one-fourth equally between the Uttoxeter Nursing Association, the North Staffordshire Infirmary, and the Derbyshire Royal Infirmary.—Mr. W. Weddell, of Hampstead, left £1000 each to the London Hospital and Dr. Barnardo's Homes, and £500 each to the Hampstead General and North-West London Hospital, St. Columba's Hospital, Swiss Cottage, the Royal Hospital and Home for Incurables, Putney, the Poplar Hospital for Accidents, St. Bartholomew's Hospital, and several other institutions.

MEDICAL SOCIETY OF LONDON.

EARACHE.

AT a meeting of this Society held on Feb. 11th Dr. J. WALTER CARR, the President, being in the chair, a discussion on this subject was opened by Dr. H. MORELAND MCCREA from the

Standpoint of the General Practitioner.

Earache, he said, might be a localised pain, a referred pain, or a transferred pain, and it was important to remember, when confronted with the complaint that there was an intimate nerve connexion between the ear, the teeth, the tonsils, the larynx, the cervical plexus, and even the heart, the main lines of this nerve Clapham Junction being the vagus, the fifth cranial, and the glosso-pharyngeal. He had seen a striking example of transferred pain in a patient whose attacks of angina pectoris always began with violent earache. The first problem to be solved by the doctor seeing a case of earache was to ascertain whether the pain was due to a lesion of the auditory apparatus or not. A neglected otitis media might be one of the most serious conditions which the general practitioner was called upon to treat; there were 1047 deaths from this in England and Wales last year. Pain in and discharge from the ear were frequently caused by furunculosis in the skin lining the external auditory meatus. *Staphylococcus aureus* was usually present in this. Sometimes earache with deafness and some swelling was due to the presence of aspergillus nigra. Minor causes of earache might be the presence of cerumen in the meatus, increase of atmospheric pressure due to blocking of the tubes, or a catarrhal cold. After every injury such as a fall on the head the auditory apparatus should be carefully examined. If no local cause for the earache could be found, regions from which pain could be transferred or referred should receive attention; especially should teeth and tonsils be inspected in a good light. Earache due to acute tonsillitis might persist even after the tonsils had been enucleated. Intense pain in the ear sometimes ensued from a buried wisdom tooth. Ulceration or erosion of the tongue could cause earache, and when this was the case the symptom was aggravated by the mastication of food; it could also accompany early cancer or tubercle of the larynx. Theoretically, sinus trouble ought to be a cause of earache, but he had not met with such a case.

Mr. HERBERT TILLEY dealt with the subject from the

Standpoint of the Aural Surgeon.

The gravity of the lesion, he said, might bear little proportion to the severity of the pain. A furuncle of the meatus, though of little danger to life, might render life intolerable for days because of the acute pain, while an earache which amounted to no more than discomfort might be the only subjective symptom of retained sepsis close to the temporal meninges.

Of *intrinsic causes*, a foreign body pushed into the meatus of a child might have caused laceration and pain. If the body was a small bean or grain of corn which swelled under warmth and moisture, intense inflammation might spread to the tympanic membrane. If not impacted the body might be removable by gentle syringing. Otherwise under a general anæsthetic a curved probe or hook should be used, under a good light, for its removal. In adults there might be a foul pledget of wool which had been forgotten. It was not unusual for a collection of cerumen to cause earache when it pressed against the tympanic membrane; patients might even complain of vertigo. One must not mistake for wax, however, the brown coloured adherent accumulation in the depth of the meatus known as a cholesteatoma. This was frequently associated with chronic suppuration in the tympanum or mastoid antrum and cells. When furunculosis occurred in the ear, owing to the resistance of the parts, the pain was continuous and intolerable

and any movement of the mandible accentuated the pain. Unless the drum membrane was involved, however, hearing was not affected. In the differentiation of mastoiditis from furuncle the following points should be remembered: The hearing would probably be normal in the case of furuncle, but not likely to be so in mastoiditis. If meatal inflammation alone was present any movement of jaw or auricle would greatly accentuate the pain, but that of mastoiditis would be scarcely increased by it. Direct pressure on the oedematous area would not greatly accentuate the pain of furuncle, but it would definitely do so when inflammation was present in mastoid antrum or cells. If the case was difficult and one could not exclude mastoid involvement, the region should be explored and the furuncle freely opened. The risk of this would be much less than that of leaving a possibly infected mastoid without free external drainage. In treatment hot fomentations over the auricle and the insertion of a strip of gauze soaked in warm lotio plumbi et opio might relieve the early inflammation, and the internal administration of aspirin, pyramidon, or similar remedies greatly lessened the earache. If, as was usual, the pain continued, a brief general anæsthetic should be given, the meatus sterilised, and a free, deep incision made into the abscess. Relief followed immediately. A staphylococcus vaccine often prevented a recurrence of the furunculosis.

Acute inflammation of the middle-ear cleft provided the physician with most of his cases of severe earache, and it was practically always accompanied by symptoms of a general toxæmia. Infection occurred by way of the nasopharyngeal orifice of the Eustachian tube. Middle-ear infection was common between birth and puberty, because then the nasopharynx had its full complement of lymphoid tissue, tissue which constituted an excellent medium for the growth of micro-organisms. He impressed on students that when they were called to an infant who was restless, fretting, or screaming, the abdomen or the ear should be regarded as the most likely seat of the trouble. If the abdomen could be excluded each tympanic membrane should be examined, and with present hospital facilities it should be easy to detect the difference between a normal opalescent tympanic membrane and one which was red and congested. The infant's hand would be tossed towards the affected ear, and the child would tend to lie with the inflamed ear uppermost. Some pyrexia would always be present, and some gave to the symptoms the name "meningism." There might be no discharge until these symptoms had lasted 24 to 48 hours or longer, and it was not wise to wait for discharge before attempting a diagnosis. If, however, discharge had commenced when the patient was first seen the meatus should be cleaned and an effort made to ascertain the site and size of the perforation in the tympanic membrane and the condition of the meatal walls. A magnifying Siegel's speculum would facilitate this. With regard to treatment, if acute inflammation of the intact tympanum was present the tympanic membrane could be incised under general anæsthesia in a child, while in an adult anæsthesia could be produced by applying a solution containing cocaine, carbolic acid, and adrenalin chloride. It was his firm conviction, said Mr. Tilley, that when the tympanic membrane was acutely inflamed and uniformly congested, paracentesis should be performed; clean and free incision through the posterior half of the drumhead gave immediate drainage, and so saved the delicate middle ear from possibly irreparable damage, and might also hinder the spread of infection to the mastoid antrum. If, on the contrary, one waited for spontaneous rupture of the membrane to take place suffering would be prolonged and danger would be increased. Pain on pressure over the mastoid was practically always present during the first few days of an acute inflammation of the middle-ear cleft, but it did not always call for immediate surgical exploration.

Milder and more fugitive forms of earache in children should be regarded as a warning of infection of Eustachian tube and middle ear, and adenoids would be frequently found in these cases. Inflammations of the middle ear met with in the course of influenza were often rapid in onset and severe in degree, and there might be found hæmorrhagic blebs on the deep meatal walls. Here early incision of the membrane was even more essential than in the more common types of inflammation. In chronic suppurative otorrhœa earache should be regarded as a symptom of significance, as it meant that septic products were being retained under tension in the middle ear or its adnexa. It was necessary to make free exposure and drainage of a septic focus. Earache, too, might be complained of by patients having chronic non-suppurative inflammation of the middle ear cleft which had produced cicatricial changes in the tympanum, or a sclerosis of the mastoid bone. The pain in these cases was usually dull and boring.

Of *extrinsic* (or referred) *earache*, one seat of trouble was the sphenoidal sinus and its neighbourhood. A lady suffered from bouts of pain every four or five days, and the sudden cessation of symptoms always followed a feeling of something having burst in the head, when she had an unpleasant smell in her nose. Drainage of the sphenoidal sinus entirely cured her. An essential condition for the transference of pain from a visceral region to the body surface was that the ganglion cells of the afferent fibres of both these regions should be located in proximity in the same sensory ganglion, while centripetal processes from both sets of cells passed together into the bulb.

Discussion.

Sir JAMES DUNDAS-GRANT spoke of methods of examining the tonsil to avoid missing disease. If the tonsil were anæsthetised with guaiacol and olive oil and the ear pain then ceased, one knew the tonsil was the cause of the earache. Many patients sent for urgent mastoid operation were found to have furuncle; it was a real trap. Often an enlarged submaxillary gland caused earache; a concretion in Wharton's duct had the same effect. In one case of severe earache he found an epitheliomatous ulcer at the root of the tongue.

Dr. T. H. JUST emphasised the great value of the electric auriscope in practice, though it was not popular with some older practitioners. Some held that to operate on the mastoid in a doubtful case and find the condition was furunculosis was anathema, but it was playing for safety, and was no more to be criticised than removing the appendix needlessly. Herpes zoster oticus was, he considered, easy to diagnose in the early stages, but not always so if neglected when facial paralysis might be present and nerve deafness severe. Diagnosis rested on hearing and labyrinthine tests.

Mr. HAMBLIN THOMAS said that if streptococci got into a small abrasion behind the ear in a child the condition might be mistaken for acute otitis media. Sometimes an accumulation of wax had, by pressure, eroded the skin, so that even after removing the wax the pain might persist, calling for local treatment. Carbolic acid and glycerine instillations into the ear might relieve pain for the time, but they might remove the superficial layers of epithelium. People with high blood pressure and arterio-sclerosis might have very definite earache in consequence.

Dr. E. C. STEELER said he had always found it safer and better at once to open an inflamed and protuberant drum than to allow it to rupture of its own accord.

Reply.

Mr. TILLEY said that if there was present an early stage of malignant disease of the middle ear, the light touching of the small granulations with a probe caused instant bleeding. Concretions due to other causes, however, bled to a less degree, and only after there had been considerable manipulation of them. He had seen only two cases in 30 years of pain in the ear due to sphenoidal sinus suppuration.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting on Jan. 10th, a discussion on

THE INJECTION TREATMENT OF VARICOSE VEINS

was opened by Dr. STUART MCAUSLAND. He said that from the histological aspect the process of vein obliteration by injection was essentially a chemically produced irritation of the endothelium which caused the formation of a firm clot; the fact that the clot was firm, together with the phenomenon, radiographically confirmed, that the circulation in varicose veins was downward, and with the innumerable clinical successes which had been obtained without accident, negatived all danger of embolus. Having discussed indications and contra-indications, Dr. McAusland described the technique used by him, and gave the results of his own cases, together with after-effects. He concluded that salicylate of soda and quinine with urethane were the substances of choice; that patients should rest the limb for 20 minutes after injection; and that the advantages of the method were exactly those of hæmorrhoid injections. The treatment was essentially ambulatory, nearly painless, and much cheaper than operation; it was more successful than excision, smaller radicles being reached; recurrence was less likely. The treatment, moreover, avoided the risks associated with operation, such as general anæsthesia and post-operative embolus.

Mr. H. F. WOOLFENDEN emphasised the apparent safety of injection treatment, in so far as the risk of pulmonary embolus was concerned. The thrombus formed was firm in character, the thrombosis being secondary to the chemical endophlebitis and resembling the tough fibrinous thrombus met with in aneurysm. The convenience of the treatment from the patient's point of view was undoubted and the cure seemed to be as likely to be permanent as that resulting from operation. Certain disadvantages of the method had to be considered. The first was pain, which was sometimes met with at the time of injection when sodium salicylate was used, but it was generally for some days afterwards that patients complained at times of pain and tenderness on the leg. This might possibly be due to part of the injection being outside the vein or to a leak back at the puncture hole in the vein, but it also occurred when the injection was undoubtedly in the vein and was then due to an excessive reaction, causing periphlebitis. This excessive reaction had four possible causes: (1) stronger solution; (2) stagnation in the vein; (3) thinness of the vein wall; and (4) idiosyncrasy of the vein. There was also the possibility of errors in technique causing slough formation by injection outside the vein. This should not occur, but unfortunately it did so occasionally. As to the relative advantages of quinine, sodium salicylate, and sodium chloride, quinine and urethane were most suitable for the peripheral injection of small and moderate-sized veins, but sodium salicylate and sodium chloride given by Colt's technique were excellent for large varices involving the long saphenous system on account of the speed with which cure could be obtained. It was important to bandage the leg after injection, so that the formation of large bulky clots could be avoided.

Mr. J. B. OLDHAM said that on the question of safety of injection treatment, the sceptics advanced the objections: (1) the risk of general toxic symptoms; (2) local complications; and (3) pulmonary embolism. Severe symptoms attributable to excessive doses of quinine had been known to occur, but the speaker found that all these could be obviated by (1) giving a very small initial dose ($\frac{1}{2}$–1 c.cm.) to test the patient's susceptibility, (2) giving not more than 7–8 c.cm. at one sitting, (3) keeping the limb at rest for half an hour after injection. Sicard had supplied experimental proof that solutions injected in varices remained in situ, if the limb was kept at rest, but quickly entered the general circulation when active movement was allowed, and Mr. Oldham had himself made a similar observation following injection of methylene-blue. Local necrosis was almost alway the result of the solution entering the subcutaneou tissues—an error in technique—but occasionally as Mr. Woolfenden had mentioned, necrosis followe what had apparently been a perfect injection Embolism was a theoretical possibility, but th practical clinical evidence of many hundreds o thousands of injections without a fatality—no cas of fatal embolism following a sodium salicylate o quinine injection had been observed—was more tha sufficient to outweigh this theoretical danger. In spit of the unlikelihood of the occurrence of embolism the following precautions were advocated: (1) th patient should not move for half an hour afte injection; (2) technique should be scrupulously aseptic; (3) if possible, excessive muscular activit should be avoided for three to four weeks afte completion of treatment. The advantages ove the operative methods were enumerated, and i was pointed out that one fatal case of embolism happened in every 700 or 800 major operations Mr. Oldham thought that a tourniquet was help ful, and that injections should be given with th patient lying down; quite independently he had com to the same conclusion as had Mr. Woolfenden as t the great advantages of supporting the veins with a bandage for a few days after injection. In case with a positive Trendelenburg sign, good result could often be obtained by a single injection made a proximally as possible, the consequent fibrosis being equivalent to the old Trendelenburg operation and protecting the distal veins from the passive downward reflux of blood.

MANCHESTER MEDICAL SOCIETY.

AT recent meetings of this Society, with Dr. R. W MARSDEN, the President, in the chair, Dr. C. S. D DON read a paper on the

Treatment of Exophthalmic Goitre.

An attempt was made to compare the three line of treating this condition at present adopted— namely, (1) iodine therapy, (2) X ray therapy, an (3) operative procedures. The improvement o otherwise was gauged by a comparison of the basa metabolic rate, the weight, and the pulse before an after treatment. It was found that iodine produce a temporary fall in the basal metabolic rate an pulse and an increase in weight. The fall in th basal metabolic rate and pulse lasted for about month, in some cases longer, while the increase i weight in nearly all cases continued for about fiv months. Iodine by itself cannot cure exophthalmi goitre, and if given and then stopped a second cours has less effect. A number of cases who had X ra therapy for periods over a year were examine repeatedly at intervals of three months, the basa metabolic rate being estimated on each occasion out of a total of 30 cases improvement or cure wa noted in 54 per cent. In 27 per cent. of cases th basal metabolic rate and pulse-rate were found t have returned to within normal limits—regarded a the criterion of cure. Operative procedures were the considered, attention being drawn to the value iodine in preparing for operation. Of 12 cas operated on at least eight months before the date examination a fall in the basal metabolic rate an pulse to normal was found accompanied by a increase in weight in 75 per cent. Of 18 cases ex mined before iodine was given, after iodine was give and two weeks after operation, cure was noted 85 per cent. As a result of his observations D Don advocated X ray therapy without iodine admini tration for six months, and at the end of this perio if the basal metabolic rate and pulse had not cor down considerably, the patient should be giv iodine and then operated on. Cases with bas metabolism of plus 35 per cent. or over should treated by a preliminary ligation; those with a bas metabolic rate below plus 35 per cent. should ha four-fifths of the goitre removed by thyroidectomy.

Reviews and Notices of Books.

)ISEASES OF CHILDREN.

First edited by Sir ARCHIBALD GARROD, F. E. BATTEN, and HUGH THURSFIELD. Second edition edited by HUGH THURSFIELD, D.M., F.R.C.P., and DONALD PATERSON, M.B., M.R.C.P. London: Edward Arnold and Co. 1929. Pp. 1106. 45*s*.

THE appearance of a second edition of this book fter an interval of 15 years will give genuine satis- action and pleasure to medical readers throughout he country. The editors have earned the gratitude of he profession by perpetuating a work which has long emained the most comprehensive and representative roduct of British pædiatrics. The untimely death n 1918 of Dr. Batten removed a great authority on he neurology of childhood; however, continuity of he book has been well preserved by Dr. Thursfield, n collaboration with Dr. Donald Paterson, and aluable contributions from the pen of the original enior editor are included. The revision of so well- nown a work, the individuality of which has as much o do with its form as with its content, must of ecessity present problems of great difficulty. The ditors have made it their object to preserve the riginal arrangement wherever possible. In the reater part of the book sequence of the subject natter of the chapters is similar to that of the first dition, though occasionally the account of a disease as been transferred to a more appropriate section as result of an altered view of its ætiology.

The "prolegomena" appears in shortened form;)r. Gossage's article on heredity remains, and that on nmunity has been rewritten by Dr. D. McLean and Ir. Eric Lloyd. A number of articles have been evised by their original authors, for example, those y Prof. F. Langmead on the new-born, Dr. H. Morley letcher on liver and peritoneum, Dr. Thursfield on he hæmopoietic system, and Dr. J. W. Carr on uberculosis. In some chapters additions and lterations have been made by a new author, the riginal features of the article being preserved; mong these are the sections on respiratory isease, metabolic disorders, and organic disease of he nervous system. An equally high standard has een attained in those chapters which are wholly r mainly new. That on nutritional disease has been ewritten by Dr. L. G. Parsons. The disorders which e describes—infantile atrophy and rickets—are mong those which show most evidence of the advance f knowledge during recent years, and his contribution rovides a lucid statement of modern views on their ausation and treatment. Additions have also been nade to the section on alimentary diseases; more pace is devoted to surgical conditions, and a notable eature is Dr. Reginald Miller's account of cœliac isease. In the chapter on cardiac disease Dr. G. A. utherland has achieved a triumph of condensation, nd has given in a remarkably small space a really lear description of its manifestations, considered in elation to their effects on the genetic, contractile, and alvular systems. The articles by Dr. E. A. Cockayne n the ductless glands and Dr. J. C. Spence on the enito-urinary system both give readable and up-)-date accounts of subjects upon which current pinion has recently undergone much change.

The chapters on the nervous system show the ifficulties of the revision of a work of this kind; a ivision into functional and organic diseases is not so asily achieved as in 1913. The spasmophilic neuroses ave been removed from the section on functional iseases and are considered under rickets, but onvulsions and epilepsy remain, the latter being dealt ith by Dr. W. G. Wyllie. The conditions commonly lassed as neurotic are described by Dr. H. C. Cameron, ho has incorporated some passages known to readers f his works on children's disease. Great praise must e accorded to Dr. Wyllie not only for what he has ontributed himself—such as his excellent article on ncephalitis—but for the skill with which he has preserved the individuality of Dr. Batten's chapter on organic disease. The same high standard is reached by Dr. F. J. Poynton on rheumatism, Dr. B. Schlesinger on infectious diseases, and other contributors, all of whom are authorities on their subjects. A welcome innovation is provided by Mr. P. G. Doyne's concise summary of ophthalmic disease in childhood.

This book has already won its place in the foreground of pædiatric literature, and the editors have done all that can be done to ensure that the second edition will maintain this position.

DIAGNOSIS IN HEPATIC DISEASE.

Praktische Differentialdiagnostik. Für Aerzte und Studierende. Herausgegeben von Prof. GEORG HONIGMANN. Band I. Innere Medizin. Teil 5. *Erkrankungen der Leber und Galle*. By Dr. Karl Glässner, Professor at the University of Vienna. 1929. Dresden and Leipzig: Theodor Steinkopff. Pp. 392. M.4.50.

THIS comprehensive new work written by clinicians working in Giessen, Vienna, Düsseldorf, Breslau, Munich, Cologne, and several other centres in south Germany and Austria is now appearing in handy instalments. There are seven volumes devoted to special branches of medicine or surgery. Each volume is divided into several parts and each part is entrusted to one author. The parts are printed separately and they vary in price and size, the average being 6 marks and 100 pages respectively. Part 5 of Volume 1, on liver and gall-bladder diseases, is written by Dr. Glässner of the University of Vienna. It is a very practical and complete little brochure, well arranged and concise. The author stresses the importance and unfailing value of a thorough physical examination of the patient. Clear accounts are given of radiological methods of investigation and analyses of bile obtained by a duodenal tube. Cholecystography is not, however, given sufficient recognition. The chemical tests of liver function are well explained, but they take a place in the author's technique second to the bed-side clinical investigation by the classical methods. There are no charts or diagrams, and the appearance of spaced lettering on almost every page is a little distracting to the English reader. Some useful tables of differential diagnosis between maladies like "Wilsonsche Krankheit" and "Malarialeber" are included. A large bibliography has the advantage of being quite up to date. It indicates that the author has drawn freely from the writings of Hijmans v. d. Bergh, Aschoff, Chauffard, Wilkie, Eppinger, and Franklin.

THE PROBLEM OF FERMENTATION.

By M. SCHOEN, Institut Pasteur. Translated from the French by H. LLOYD HIND, B.Sc., F.I.C. London: Chapman and Hall, Ltd. 1928. Pp. 211. 21*s*.

THE study of fermentation has played a great part in the history both of medicine and of chemistry. Lavoisier, Gay-Lussac and Liebig, Dumas, Claude Bernard and Pasteur, all these great men and many others have in the past been closely connected with the development of this "most striking and extra-ordinary reaction," as Lavoisier described it. Nor has its significance diminished as knowledge grew. Lavoisier deduced in part from the study of fermentation his statement of the law of the conservation of matter; Pasteur was able to recognise the function of yeast in alcoholic fermentation, and thus laid the foundations of modern microbiology; the work of Liebig, Berthelot, and Büchner led to the modern theory of enzyme action; and in our own day the researches of A. V. Hill and O. Meyerhof have thrown light on the action of living muscle, a subject which has been a source of mystery to investigators since lactic acid was first shown to be a product of muscular action. Hill, by his brilliant micro-calorimetric researches, has been able to explain the phases of muscular contraction, whilst the work of Meyerhof has placed the whole subject on a quantita-

tive and mathematical basis. During the past few years O. Warburg's studies in Berlin have also aroused much interest. He has been able to demonstrate the quantitative difference between normal and malignant tissues as regards glucose metabolism, and here, also, there are certain resemblances in metabolism to that of yeast in the fermentation of carbohydrate.

Prof. A. Fernbach, in his introduction, points out that this book is not so much a complete dictionary of facts as a summary of the ideas to which they give rise. Alcoholic fermentation forms its principal theme, but sufficient space is given to various other aspects of fermentation to stimulate the reader's curiosity. The opening chapters contrast the theories of Pasteur with the enzyme theory of fermentation; bacterial fermentation, and the relation of fermentation to respiration are also considered. The theories in which various intermediate substances in the alcoholic fermentation of sugars are postulated are discussed in some detail, and the function of phosphates in alcoholic fermentation and Harden's theory are dealt with in the succeeding chapters. The final sections are concerned with the influence of the reaction of the medium, and the processes of oxidation and reduction on these reactions. The inclusion of a chapter on hydrogen-ion concentration and its determination appears to be unnecessary, since numerous general text-books of physiology and biochemistry deal adequately with the elementary aspects of this question.

The subject of fermentation is a vast one, to which this monograph may be considered a useful introduction. It contains an extremely useful, up-to-date and well selected bibliography.

ROENTGEN DIAGNOSIS OF ECHINOCOCCUS TUMOURS.

By GUNNLANGER CLAESSEN. Stockholm: Acta Radiologica. 1928. Supp. 6. With 86 illustrations. Pp. 155.

THIS small volume from Iceland is founded on a most careful clinical and radiological research, financed by the University of Iceland, into 44 cases which came under the author's observation. Thirty-seven of these were primary in the liver, and he draws the conclusion that, in Iceland at any rate, primary pulmonary echinococcus cysts are exceedingly rare. In England we so seldom see patients suffering from this infection that there is little literature apart from scattered references and sporadic records of isolated cases. Consequently, the radiographic appearances and diagnostic points have not been very clearly defined. The only other considerable record of radiological investigation of echinococcus that we have seen comes from New Zealand where hydatid disease appears to be comparatively common. C. C. Anderson's work was published in the *New Zealand Medical Journal* of August, 1926. (See also *British Journal of Radiology*, November, 1928.)

Dr. Claessen is to be congratulated on an excellent and complete thesis.

CHARLES DARWIN.

The Man and His Warfare. By HENSHAW WARD. London: John Murray. 1928. Pp. 472. 21*s*.

THE author of this book is interested in the man Darwin, as who could fail to be, but he is even more interested in his warfare. To him Darwin is the protagonist of true science, who with his weapon of observation defeats the forces of theory and speculation. For 2000 years mankind had toyed with the theory of evolution, but it remained a theory till Darwin came. It is his peculiar merit that in an age of speculation he refused to be satisfied with the views of biologists, the beliefs of theologians, and the conclusions of philosophers. Darwin had no use for the doctrine of the armchair theorist, prevalent even to-day, that by intense thought the superior mind can create knowledge. He demanded facts, and he could never have enough of them. For a man with his genius for accurate observation and enormous industry the five years spent on the *Beagle* were invaluable. But they were merely the prelude to 23 strenuous years during which in spite of persistent ill-health the "Origin of Species" was gradually evolved. How the Darwinian doctrine was developed and how it was received is graphically described by Mr. Henshaw Ward. We are so prone to take things for granted that it is difficult to realise the storm of controversy which Darwinism excited only half a century ago. But the author has successfully recaptured the atmosphere for us—and he has done even more, for we finished his book and then turned once again to the "Origin of Species."

THE TEETH AND THE MOUTH.

By LEROY HARTMAN, D.D.S. London: D. Appleton and Co. Pp. 93. 5*s*.

THE great interest taken by the lay public in the teeth has led to the production of a number of books which, written in non-technical language, attempt to convey the principles of dental hygiene with varying success. This work is an example of what in America is called the quiz book, and consists of questions and answers. The method may be well suited to convey potted knowledge to the student preparing for an examination; it is not necessarily the best way to educate the public in technical matters, though it has the advantage, possibly a doubtful one, that it can be read in snippets and does not make any serious call on the attention of the reader. But within limits the book does manage to convey a large amount of useful information of a practical kind on the hygiene of the teeth. The information generally is on sound lines, though in a book written primarily for an American public the various dietaries advised include certain articles of food unknown here. There are a few pieces of advice which seem to us rather unwise. For example, the question is asked as to what should be the treatment if a child should dislocate a permanent incisor from the mouth. The answer is that the tooth should be picked up, washed in salt water and replaced in the socket. Apart from the risk of tetanus, not entirely negligible, such a tooth should only be replaced by the dentist after the pulp has been removed, the root canal filled, and some more adequate method of disinfection carried out than that recommended.

WHAT IS LIFE?

By AUGUSTA GASKELL. London: Baillière, Tindall and Cox. 1928. Pp. 324. 16*s*.

Mrs. Gaskell proposes that life is a quantity, made up of the same ultimate constituents (electrons) as matter but differing from matter in the manner in which these ultimate units are combined. This quantity varies and forms a series, comprising a very large number of different forms and variations of forms. The quantity life is regarded as identical with soul and mind. An organism consists, therefore, of two systems—material atomic, which is its substance, and immaterial intra-atomic, which is its life. Death is the dissociation of these two systems. As Prof. K. T. Compton and Prof. Raymond Pearl respectively point out in introductions which they have written to the book, Mrs. Gaskell's theory is credible in the sense that it is nowhere grossly discrepant with what are believed to be the assured data of physics and biology. But there is no direct evidence in its favour and its truth fails entirely if it is tested by the modern criterion of fruitfulness; for all that the authoress asserts to the contrary, we judge that it explains nothing and suggests nothing. Nor do we understand how it can be tested by any critical experiments, though Prof. Pearl seems to accept Mrs. Gaskell's claim that this can be done. We cannot advise anyone to spend much time over the book; those who are interested in such problems would do better to read Prof. A. S. Eddington's Gifford Lectures from which Mrs. Gaskell would learn that electrons are not quite the ultimate verities which she seems to think them to be.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 16, 1929

CEREBRAL SURGERY.

IT is well at times to recognise that there are forms of mutual indebtedness between nations which excite no feelings but gratitude. Such are the contributions of each to the common stock of knowledge, and no better example of these could be found than the remarkable development of neurological surgery which the world owes to the United States, and, in particular, to the genius of Dr. HARVEY CUSHING. Many of the fruits of CUSHING'S work during the last 25 years have long been available in his publications and in those of his pupils. There is, however, another aspect of a surgeon's work, and perhaps the most important, which is much less readily communicated to others—his technique. There is no limit to those who can read his papers, but comparatively few are privileged to see him at work and to judge his craftsmanship by the final and inexorable test of its results in his patients. For this reason both surgeons and neurologists will read with great interest Mr. HUGH CAIRNS'S "Study of Intracranial Surgery," [1] which is an account of his year's experience as assistant resident surgeon in Cushing's clinic. During the year which Mr. CAIRNS spent at Boston, 463 cases were admitted to Cushing's clinic, including 369 belonging to the intracranial tumour group. Of these, 229 were subjected to operation, 284 operations being performed. The case-mortality was 12·2 per cent., and the operative mortality 9·8 per cent., all patients who died in hospital being accounted operative deaths. These remarkable figures, which it is safe to say have never been equalled elsewhere, will excite not only admiration but a demand to know how they are achieved, and of this Mr. CAIRNS'S book is an excellent account. His method has been to let "the cases as far as possible tell their own story," and he includes more or less detailed reports of 40 cases, together with a number of radiograms and other illustrations which have been well reproduced. But the book is far more than merely a clinical review, for he has discerned with insight the principles upon which CUSHING'S success is based, and the cases reported are subordinated to the themes which they illustrate.

Mr. CAIRNS first describes CUSHING'S clinical classification of his cases into "verified," "unverified," and "suspect," and gives a brief account of the development of a histological classification of intracranial tumours to which BAILEY has contributed so much. This is work of far-reaching practical importance, as Mr. CAIRNS points out, for it has been possible to a large extent to correlate the histological structure of the gliomas both with their malignancy and with their naked-eye appearances. Hence, in many cases the surgeon can recognise at operation the nature of the tumour with which he is dealing, estimate the prognosis, and plan his operation accordingly. Mr. CAIRNS next draws attention to a change of diagnostic outlook for which CUSHING and his pupils have been largely responsible. Neurological surgery was at first fully occupied with problems of localisation of tumours by physiological and anatomical methods. Radiography, histopathology, and endocrinology have, however, coöperated with the earlier modes of investigation to present many intracranial tumours in a new light as living objects with distinctive life-histories, thus leading to the recognition of the clinical syndromes produced by such tumours as craniopharyngeal pouch cysts, acoustic neuromas, and a number of others. This knowledge, again, is of the utmost value in preparing the surgeon for the problem with which he will be confronted on opening the skull, for modern diagnostic methods teach him not only the anatomical localisation, but in many cases the nature of the neoplasm. Under the heading Methods of Investigation, Mr. CAIRNS naturally considers mainly the more recent advances in diagnostic method, especially the examination of the fundus oculi, the investigation of the visual fields, X ray examination, and ventriculography. These methods are all by now generally familiar, and it will be agreed that the first three should form part of the routine examination of every suspected case of intracranial tumour. Methods of diagnosis, old and new, however, are of no value unless the surgeon is able to deal with the intracranial tumour which he has successfully localised and exposed. For many years technique has lagged behind diagnosis in neurological surgery. We read, therefore, with special interest Mr. CAIRNS'S account of the principles which underlie CUSHING'S surgical methods—namely, (1) avoiding injury to the brain, (2) hæmostasis, and (3) asepsis and closure of the wound. CUSHING'S patient and painstaking surgical technique is well known. Its profound influence upon the whole work of his clinic is perhaps less fully appreciated. Extremely gentle manipulation of the cerebral tissues and absolute hæmostasis are the two factors which, by largely eliminating shock from CUSHING'S operations, have most directly contributed to a reduction of operative mortality. This has had far-reaching results. Not only has it become possible to remove tumours from the brain with little local or general disturbance, but repeated operations in a short period, which in a profoundly shocked patient would have proved fatal, have been rendered practicable. Thus the surgeon has been enabled to deal with such complications as post-operative hæmatoma. Moreover, a low operative mortality-rate justifies early cerebral exploration and so leads to the removal of tumours at an earlier stage of their development than has hitherto been possible. So much for what has already been achieved. Mr. CAIRNS has something to say also about what may be termed the growing point of neurological surgery, the developments of technique which are at present in the experimental stage. Perhaps the most important of these is the application of the high-frequency current to the removal of tumours. By means of the loop electrode it has been possible to remove piecemeal highly vascular and deeply seated tumours with but little hæmorrhage. This development of diathermy and the as yet almost untried effects of radium may well greatly increase the proportion of removable intracranial tumours.

It is interesting to reflect that CUSHING'S success as a neurological surgeon is to a large extent the expression of the peculiar genius of the American people, which may be summed up in the word "technique." The supremacy of technique in American social and industrial life is obvious. Equally the great contributions of the transatlantic peoples to medicine and surgery have been technical advances, such as the growth of micro-chemical methods, the

[1] A Study of Intracranial Surgery. By Hugh Cairns, M.B., F.R.C.S., Medical Research Council, Special Report Series, No. 125. H.M. Stationery Office. 1928. Pp. 83. 3s.

isolation of insulin, and the liver treatment of pernicious anæmia. CUSHING'S contribution to neurological surgery has been the development of its technique in the widest sense of the word, including not only the diagnostic and surgical methods we have already briefly described, but also the technique of organisation, as expressed in team-work and the documentation of cases. England is notoriously suspicious of technical efficiency and likes to pretend that in this attitude lies the secret of her greatness. But this is a cosmopolitan age in which we so readily adopt our neighbours' vices that we cannot afford to neglect their virtues. It is clearly to the patient's interest that CUSHING'S methods should be practised as widely as possible, though it must not be supposed that English neurology has nothing to contribute to neurological surgery. CUSHING has necessarily been preoccupied with practical considerations and has left untouched many questions of more theoretical interest, which may nevertheless have important practical implications. Neurological surgery, in fact, offers a great opportunity for the union of the different but complementary mental qualities of the American and British peoples For in this realm of therapeutics each operation is an experiment in human physiology, and the greater its technical efficiency the greater the scope it provides for the spirit of physiological inquiry which is the basis and peculiar pride of English neurology.

LONDON CHILDREN AND THE FOUNDLING SITE.

ABOUT a year ago the future of the site of Capt. CORAM'S Foundling Hospital was the subject of keen dispute. This terminated abruptly as far as the commercial participants were concerned, when the Foundling Estates Protection Association was able to secure a Parliamentary veto to a proposal to re-erect Covent Garden Market on the coveted site. Since this time the original buildings have been demolished and several other schemes for utilising the site have been put forward. Of these the most interesting is the suggestion that the historical association of this plot of ground with the restoration of health and happiness to poor children should be preserved, and that the best known hospital for children in the British Empire should be transferred from its present inadequate buildings to new ones to be erected on this space. The Ormond-street Hospital for Sick Children has been making determined efforts to secure the site, for its governors realise the drawbacks of the existing hospital which was founded in 1852. Since that date it has been enlarged three times, not by being rebuilt but by piecemeal additions, with the result that the hospital is a patchwork affair. The position cannot be properly met by reconstruction on the present site in Great Ormond-street. The hospital is hemmed in by high buildings, particularly on the south and west, so that adequate sunlight and fresh air are lacking. These topographical and structural defects, together with insufficient accommodation for the nursing staff, for prosecuting research and for isolating and observing infectious cases, materially hinder the staff of the hospital in carrying out their work. Now, however, a unique opportunity presents itself of providing a building worthy of the hospital's great tradition as a centre of pædiatrics.

The question whether hospitals for children—or indeed for adults—are better situated in the centre of the town, or in the country, is irrelevant, for all are agreed that with the present conditions of staffing and transport large central institutions are essential, though they should be supplemented by country branches. It is hoped eventually to provide accommodation for 500 children at the auxiliary hospital at Tadworth, and perhaps in the far future the London beds of every great hospital will not be occupied for long by any individual patient. This would be a foreshadowing of the day when there will be a regular drafting of all patients that can be moved from the London hospitals to their associated county establishment. But the London hospitals will be the great and original focus, and as far as children's hospitals are in question it is a reproach to Great Britain that visitors from such centres as Vienna, Zurich, and Toronto should have to go to Birmingham or Glasgow to find institutions comparable with those in which they work. One has only to visit the Children's Hospital in Toronto, for example, to realise how woefully London lags behind other cities far less wealthy than itself in the matter of a modern children's hospital.

Within the next two or three weeks the sum required for the deposit money to secure this site will have to be obtained. If it is not, one of the most promising opportunities of our time for restoring sick children to health and happiness will have been lost.

ADENOIDS AND ENLARGED TONSILS.

THE cause or causes of enlarged tonsils and adenoids are by no means fully understood, and for the past five years a small committee of the Board of Education has been collecting information about them through the School Medical Service. As will be seen from our summary of their interim report (p. 355) no very remarkable facts have yet been brought to light, but evidence is produced in favour of certain conclusions, and plans have been made for further studies. The investigation covered 640 children, of whom 502 were found to have enlarged or septic tonsils, or adenoids, or both. It will be noticed that the Committee wisely included those cases in which the tonsils, though not enlarged, showed signs of sepsis. These 502 children are classified as "cases," and the remaining 138 are called "controls." The cases are divided as follows: 382 had tonsils and adenoids, 47 adenoids only, and 73 enlarged or septic tonsils without adenoids. From these figures it is seen that in a considerable number of cases enlargement of the tonsils was not associated with adenoids, and the Committee believe that in these the causation was probably different—an opinion contrary to that of most laryngologists, who hold that in children enlarged tonsils without adenoids are decidedly rare. The evidence gathered by the Committee suggested that adenoids are usually established before the age of 5, and that they seldom develop after 8 years, whereas the tonsils may become enlarged at any time during school life. There is a definite tendency for more than one case to occur in a family, but there is nothing to show whether this is the result of some hereditary characteristic or of similar environmental conditions. A poor state of health during the first year of life was far more common among the cases than the controls, and was usually attributable to bronchial catarrh; from the early age at which these catarrhal attacks started, they were probably the precursors rather than the consequence of the adenoids. Again, it seems certain that there is some relationship between the common infectious diseases

nd the onset of adenoids; sometimes the febrile ttack is the immediate existing cause of hyper-rophy of the lymphoid tissue, whilst sometimes, erhaps, the presence of enlarged tonsils or adenoids nakes a child more liable to infection. A far greater roportion of cases than of controls showed definite igns of old rickets, and it is not impossible that a eficiency of the calcifying vitamin which is known o be the essential cause of rickets may have some-hing to do with nasopharyngeal abnormalities. The nvestigation was not concerned with very many ases, and has suffered from the further disadvantage hat the great majority of the children, when first xamined, had already passed the stage of onset. 'he Committee have therefore decided to proceed 'ith the systematic examination of a series of nselected children from birth, so as to ascertain what actors in the early history and condition of these hildren can be related to the onset of enlarged tonsils nd adenoids. They will also examine a large number f unselected children at 5 years of age in order to arn how often adenoids and tonsils are associated ith the bony abnormalities that suggest vitamin eficiency.

HOSPITALS AND THE RATES.

DETAILS of the position of provincial voluntary ospitals in the present alteration of our rating and aluation system are given elsewhere. At the oment many hospitals do not yet know their new ssessments, while, of those who know their fate and ave appealed against it, many have not yet had their ppeals heard. But enough information is available o make it certain that the assessments display a grave ack of uniformity. The Central Valuation Com-nittee was constituted under the Act of 1925 to o-ordinate and advise. It has issued recommenda-ions to local authorities for the very purpose of ttaining uniformity. Yet the recent memorandum f the Central Bureau of Hospital Information discloses he widest variation in the scales adopted. For one ospital the scale on which assessment is based is *s. 6d.* per patient and staff bed; in another it is £5; n another the scale is to be 25 per cent. of the sur-eyor's valuation—a figure which would probably iffer markedly in different localities. There seem o be four different policies possible. The first is to e-rate the hospitals and give them not less privilege n this respect than is enjoyed, for example, by places f worship or Sunday schools under the Acts of 1833 nd 1869, or by certain kinds of municipal property. 'he admitted difficulty of this course is that it is now oo late to add hospitals to the subject-matter of the ating and Valuation (Apportionment) Act of last ear, or to vary the lines of the new local govern-ent legislation now being fixed in almost final form nder pressure of the Parliamentary time-table in a ession of which almost every moment is booked. f this course cannot be attained by public Act, it ay be possible by local Act, as at Glasgow, where all oluntary hospitals are exempt from municipal rates nder a local Act of 1866, and where the Corporation s taking steps to extend the exemption to education, oor, and lunacy rates as well. But local legislation akes time, too, and costs money, and there is no eason why this universal problem should be tackled ocally. The second course is to secure preferential ssessment on the ground that the work of the ospitals saves the rates. Some hospitals which ave a proportion of beds for paying patients favour his second course rather than the first, since they feel t is difficult for them to press for complete de-rating. Here, again, there is a precedent in a local Act; the Halifax Corporation Act of 1920 (10 & 11 Geo. 5., c. lxxvi) allows the infirmary and other local charities to be charged only 10 per cent. of the full assessment charge. The third course is the status quo, mitigated by substantial subscriptions from the local authorities under section 64 of the Public Health Act of 1925, the local bodies thus taking with one hand and giving with the other, but the hospital being left entirely at their mercy and never able to reckon upon a subscription as of right. The fourth course is simply the status quo with no relief whatsoever. If this fourth course is all that the voluntary hospitals have to look forward to, their troubles come at a singularly unfortunate time, when they are threatened with municipal competition. Recent writers—for instance, Dr. Westland Chalmers in his "Hospitals and the State"—surveying the history of hospital organisation and the provision of medical facilities in England, warn us frankly that the ring is being cleared for the final round in the fight between Voluntaryism and State services. Step by step, they say, the development of public medical services and facilities has gone forward irresistibly. The Local Government Bill is a further leap forward. Does the country want to lose its voluntary hospitals? Is it willing to see the burden of the rates used to crush them out of existence?

Annotations.

"Ne quid nimis."

THE KING.

THE official bulletins of the King's health, which appear as usual on another page, bear witness to the successful transfer of His Majesty to his country residence and to the continuance of uneventful progress. Radiological evidence has confirmed the physical examination in showing that the condition of the damaged lung has returned to normal.

IODINE.

IN 1811 a nitre manufacturer in Paris named Courtois, noticing that his vats were becoming corroded, went on to inquire further, and discovered that the copper was combining with some hitherto unknown substance in the alkaline lye of kelp. Two years later, in association with Guy-Lussac, he described the main properties of the new element, iodine, which has since been found to enter in so many ways into the life of man. While the present interest in iodine may centre round its value for preventing or curing goitre, it must not be forgotten that it plays a part in all the metabolic processes of plant and animal life. The vast literature of the subject has been collected and annotated in a recent report [1] by Dr. J. B. Orr and Dr. Isabella Leitch issued by the Medical Research Council. One of the chief difficulties in iodine investigation has been the lack of a method of analysis sufficiently delicate to determine with accuracy the very small amounts of iodine found in plant and animal tissues, but since 1922 the methods introduced by von Fellenberg have opened up new fields of research. In considering the geological distribution, for example, it has been shown that rocks belonging to the same formation from different districts may differ widely in their iodine content. The amount of iodine in soils is larger than that of rocks from which they are derived. This is in part due to the concentrating powers of

[1] Special Report Series, No. 123. H.M. Stationery Office, 1929. *2s. 6d.*

plants, as work at the Rowett Institute at Aberdeen has shown. Heavily cropping the soil tends to deplete it of iodine, and manuring with either dung or artificial fertilisers causes a marked loss of iodine. The amount of iodine in fresh water and in sea water has been the object of much research, but although marine plants are rich in iodine, the common idea that the sea is especially high in iodine content as compared with the land is not supported by facts; the earth's crust and not the sea is "the storehouse of iodine." In this respect it should be noted that in the preparation of salts from natural brines iodine is largely lost, especially in refined salt. In one analysis four different commercial salts were found to contain no iodine at all. A knowledge of this distribution of iodine in nature is important in reference to its occurrence in animal tissues. Diseased tissues, it seems, have a special affinity for iodine, possibly due to a local acidosis in the inflammatory areas.

The effect of iodine on plant growth depends on the dosage used, on the species of the plant, and on the medium to which the iodine is added. There is an optimum dosage which varies from plant to plant to get the best yield in experimental plots. Some plants, especially the beets, are much more tolerant to big doses. This has, of course, a big economic importance, for it has been shown that by iodine-manuring the total sugar yield from beet can be increased by a third. In the metabolism of animals it is very difficult to distinguish between the direct action of iodine and the indirect action through the thyroid secretion. On large animals the effects of iodine on growth appear to give varying experimental results. In three tests at Iowa the administration of potassium iodide was followed by a definite increase in rate of growth, but certain experiments in Aberdeen gave negative results. In children certain tests carried out in goitre areas show improvement in growth, but the very fact that these results occurred in goitre areas suggests that iodine intake was deficient before it was experimentally supplemented. The importance of iodine in development is indicated in the well-known experiments with tadpoles. Metamorphosis in the amphibian depends, under normal conditions, upon the thyroid secretion, and it seems that iodine produces its effects in virtue of the fact that it is an essential constituent of a compound which is normally elaborated in the thyroid. Recent work on the effect of iodine on certain tissues and organs in the normal subject has brought to light some significant facts. Iodine stimulates intestinal movements, and in excessive doses causes diarrhœa. When administered by the mouth potassium iodide causes a rapid rise in the iodine content of the blood, while the effects of iodine on the skin, whether by external application or internal administration in large doses, are well known. These results have possibly more of a therapeutic than a physiological interest; the effects produced by iodine on the sex organs come into both of these categories. It has long been believed that iodine causes injury to the sex glands, but the dosage in most of the recent experiments which appear to support this view is exceedingly high; no injurious effects occur with small or moderate dosage. These facts have a definite importance in relation to the iodine requirements of animals and man. As far as the former are concerned information is meagre. It is comparatively easy to calculate the iodine intake in animals, and this can be shown in certain experiments to vary in a ratio of from 1 to 6 parts per 1000 millions, comparing the iodine intake with the body-weight. Whether this is adequate or not is not known. In the human subject the minimum amount required daily for an adult male is calculated at 15 microgrammes (millionths of a gramme), and for a child about 50 microgrammes. The dosage necessary to prevent goitre is higher, and the lower physiological limit is placed at about 100 microgrammes per day.

The relation of iodine to thyroid secretion and goitre receives close attention in the report. We have concentrated here on some of the other aspects of iodine in agricultural and domestic economy. The importance of mineral balance in dietetics and the part played by iodine in the equilibrium of the animal organism are becoming increasingly recognised. As with vitamins on the organic side, so with iodine on the inorganic side, the infinitely little counts for much.

MINOR LESIONS OF THE FEET.

THE minor lesions of the feet are responsible for such an amount of disability among all classes, and for so much loss of time and inefficiency in many occupations, that the medical practitioner should be sufficiently acquainted with the possibilities of local treatment to know when his patient may be referred to a qualified chiropodist with benefit. Comparatively few members of our profession are aware of the change which is occurring in the practice of chiropody in this country. The chiropodist has in the past been regarded, often with justification, as a quack who, for commercial reasons, usually combined his occupation with that of hairdressing, and it is true that a considerable number of this type of inadequately qualified practitioner still remains. The Incorporated Society of Chiropodists has, however, as its main object the control of the practice of the profession, and aims at placing it upon a strictly ethical basis; the Society has inaugurated schools of chiropody at various centres, each with its attached "Foot Hospital" in which the students acquire their practical training. The courses in these schools reach a high standard and extend over one to two years. The diploma of the Society, by which the fully educated chiropodist may be recognised, is granted both to successful students of the schools and to others on passing a suitable test. To this end a reliable text-book is essential. The third edition of "Practical Chiropody," written by Mr. E. G. V. Runting,[1] has just reached us. Mr. Runting has contributed a useful article on his subject to our columns (THE LANCET, 1927, i., 51), and those who recall its message and desire to learn more details of the type of treatment the chiropodist is capable of carrying out should consult his book. The author has great experience of the subject and has avoided dogmatism where there is room for controversy; the scientific side of chiropody is admittedly in its infancy and it is too early to adopt stereotyped treatments for many pathological conditions of the foot. The chapter upon the standardisation of terms will be found especially useful, the system given being that adopted at the Foot Hospital.

SYNTHETIC CHEMISTRY 1828–1928.

THE centenary of the synthesis of urea by Fr. Wöhler in 1828 was very modestly commemorated by the Biochemical Society at their October meeting held at Cambridge. Sir F. Gowland Hopkins gave an address in which he referred to the very slow appreciation of the importance of the nature of the discovery, either by the leaders of chemical thought at the time or by the writers of text-books in the immediately succeeding period. It is, perhaps, fair to state, as does Gowland Hopkins in the fuller discourse published in the current *Biochemical Journal*, that Wöhler himself, although he refers to the synthesis as "merkwürdig," did not see that he had begun to attack "vitalism." It certainly was noteworthy that an attempt to prepare ammonium cyanate by heating the potassium salt with ammonium carbonate should yield a substance which had been known for about 50 years as an important constituent of urine. In 1836, J. Dumas, who had met Wöhler in Paris three years before, had developed so much insight into the problem of "vitalism" as to write "in my belief there are no substances which in any peculiar sense, are to be called organic. We visualise in organised beings only very slowly working forms of apparatus which act upon materials at the moment of their genesis and thus produce from a very few elements very various organic compounds."

[1] Practical Chiropody. Third edition. By E. G. V. Runting, F.I.S. Ch., Founder and First President of the Incorporated Society of Chiropodists. London: Faber and Gwyer, Ltd. 1928. Pp. 200. 5s.

the present time vast numbers of organic compounds have been synthesised; in fact, the late Raphael Meldola wrote a fairly thick volume of short descriptions of syntheses of such compounds, and since his untimely death in 1916 many more have been added to laboratory arts. It must not, however, be thought that great cause for jubilation exists. Nature does all her organic chemistry within a very small range of temperature and with very mild reagents, with very limited variations of pH. Fusions with alkali, treatment with powerful dehydrating reagents, and sealed tube reactions under pressure are unknown to her. In plain fact, the syntheses of the laboratory are almost invariably performed in a manner which would destroy the apparatus in which Nature works. Furthermore, Nature has retained the secret of optical activity, leaving to Art the perpetual disappointment of synthesising racemic forms only. The great value of syntheses, a value far outweighing the commercial advantages of cheap and pure products, is the great light which a not too violent method of artificial formation throws on the constitution of the substance formed and on its affinities with other bodies. It is true that certain well-known vegetable products, such as alizirin, the colouring matter of madder, and indigo, can now be prepared more cheaply and satisfactorily in chemical works than in the field, but this is largely due to the fact that a new scientific industry has competed with and conquered an old empirical one. It is conceivable that the botanist, the biochemist, and the agriculturist may yet find means whereby the leisurely and cosmically economical methods of Nature may again, and this time successfully, be brought into competition with Art, and synthetic chemistry be directed with even greater vigour to its task of discovering absolutely new compounds, which may be, as many have been, powerful agents against disease or useful in the arts. From the synthesis of urea to that of thyroxin about a century elapsed. What will the next hundred years bring?

GANGLIA.

GANGLIA are frequently seen in any surgical outpatient department, but either they have not been studied so carefully and thoroughly as are other less common lesions or their pathology presents exceptional difficulty. At any rate, numerous speculations have been made concerning their pathology, origin, and nature and discarded from time to time. In an exhaustive study recently published,[1] Dr. Louis Carp and Dr. Arthur Stout point out that a ganglion has been called a "knot of tissue" containing "mucoid flesh" (the Hippocratic description), a retention cyst, a neoplasm or degeneration cyst; it has also been described as due to herniation or rupture of a tendon sheath. They themselves believe that ganglia arise by a mucinous degeneration of the collagenous fibrils in the fibrous tissue of joint capsules and tendon sheaths. They have observed under the microscope tiny areas of degeneration which coalesce to form small cysts. In the walls of these cysts the lumen of the vessels is conspicuously diminished by fibrosis, and it has been suggested by some writers that the constriction of these vessels causes local impairment of nutrition and degeneration of the fibrous tissue of the cysts. Dr. Carp and Dr. Stout, however, consider these changes to be secondary because they have found healthy capillaries passing through areas of degeneration, giving them an adequate supply of blood. They make no attempt to explain the cause of the mucinous degeneration. The wall of a ganglion is composed of fibrous tissue and the cavity is lined by a dense smooth, white membrane also composed of fibrous tissue, but in a condensed form. There is no epithelial lining. The cysts do not necessarily communicate with joints or tendon spaces, but they may do so if the degeneration is severe. There is usually a chief cyst surrounded by numerous accessory cavities. Trauma has been suggested as a predisposing cause, but trauma in the region of the wrist is a common occurrence and ganglia relatively rare. A conspicuous feature in the ætiology of ganglia is their occurrence in females of slight build between the ages of 20 and 40. In old age ganglia are rare. The selection of the best method of treatment is of great practical importance. Serious symptoms are rare, and deformity is usually the reason given by patients who want treatment; but interference with function and weakness do occur, and pain may be present in some cases, especially those in which a nerve is surrounded by the ganglion. Since recurrence is usually due to incomplete removal, any operation to be successful must be extensive and often involves a prolonged and difficult dissection. For this reason, and also because ganglia sometimes disappear spontaneously, Dr. Carp and Dr. Stout consider it desirable to reserve operative treatment for those cases which do not yield to simpler methods. They have had fair success from rupture of the ganglion, either by gradual pressure or by a sudden blow, and also from aspiration of the contents followed by injection of an irritant such as tincture of iodine. Pressure should always be applied for some time after any non-operative treatment. When an operation has to be performed a general anæsthetic should be given. These conclusions are based on the late results of 70 cases, and will confirm the impressions of many surgeons whose experience of the results of operation has not been encouraging.

THE MENINGOCOCCUS.

Cerebro-spinal fever is a disease of peculiar interest to the clinician, the sanitarian, and the bacteriologist, all of whom should welcome the publication of Dr. E. G. D. Murray's monograph[1] on the organism which causes it. Of the useful "green books" issued by the Medical Research Council, this is the fifth to deal with the disease. The *Diplococcus intracellularis meningitidis* is an obligatory parasite which has never been found apart from human beings; in normal times it lurks among the population of England in an almost imperceptible form, living in a few noses and throats, generally causing no symptoms, sometimes producing a catarrh and occasionally a frank case of meningitis. Under certain circumstances, the most important of which appears to be the close aggregation of large numbers of susceptible people, the organism rouses up, spreads widely through the exposed population, and causes enough cases of meningitis to constitute an epidemic. These striking epidemiological facts have been already largely elucidated by bacteriological methods which alone have made it possible to identify the carriers, and no doubt their further explanation depends mostly on our knowledge of the organism on the one hand, and the reaction of the body on the other. Dr. Murray has brought together all that is known about the organism; his references to clinical medicine, pathology, and hygiene are only incidental, though his last two chapters—on human infection and on diagnosis—are of immediate sanitary importance. He reviews in order the morphology, physiology, virulence, toxin production, and immunity reactions, and in his closing paragraphs points out how the habitual neglect to study the biology of bacteria for its own sake has sadly hampered progress along purely utilitarian lines. It is impossible to notice all the points of interest which arise—the whole should be read as a coherent tale. Most are of specific moment, but scattered about are many items of wider importance—e.g., the possibility of drying the organism without killing it, and the exaltation of virulence which may be produced quite quickly by growing it in leucocyte extracts.

Dr. Murray's book will be very useful to working bacteriologists, but it will not escape criticism in various directions. It contains no summaries for hurried people, and it is not always easy to make out

[1] Medical Research Council Special Report Series, No. 124. H.M. Stationery Office. Price 3*s* 6*d*. pp. 142.

what Dr. Murray's considered opinion really is—for example, as to what really is the best medium on which to grow the organism. His remarks (p. 56) on virulence are obscure, and it is not clear how his own view differs from the traditional ideas which he misstates and condemns. The whole question of virulence and minimum lethal dose, to which he devotes much attention, seems to be in an unsatisfactory confusion. The fatal dose of dead bacteria may be only 20 times the M.L.D. of live organisms, from which we may judge that the mice injected with live meningococci die of poisoning as much as of infection—an old-fashioned distinction to which Dr. Murray might pay more attention. If as much as 4·0 mg. of moist bacteria are needed to kill a mouse weighing 20·0 g. (equivalent to nearly half an ounce for a man), the experimental conditions cannot be thought of as even remotely approximating to the conditions of natural infections. Small wonder that the author concludes (p. 57) that "the measurements of virulence as a laboratory test must of necessity be a death struggle" in which we hope Dr. Murray will be the survivor.

INHERITED RESISTANCE TO INFECTION.

EVIDENCE has been accumulating during the last few years tending to show that the power of resistance to infection is a factor inherited according to Mendelian laws. Up to the present investigations along these lines have been mainly concerned with the exanthemata and the results have been far from conclusive. Recent investigations on the incidence and severity of tuberculous infection in members of the four blood groups promise to throw more light on the matter. The results of this work were first published in the course of the past year by Z. Swider and N. Kon,[1] and seemed to show clearly that members of Group A (II Moss) were more susceptible to this type of infection than those of the remaining three groups. More recently the same authors, in conjunction with Mlle. M. Mancewiczowna, have studied the matter from another angle.[2] Taking 300 tuberculous patients, they divided these according to the stage of the disease into Turban's three classes. On investigating the blood groups of all these patients they found that, whereas in Groups O and B there was a steady decrease in the percentage from Turban's Class I. to III., in Group A the reverse was the case. Thus while in Groups O and B the percentage in Class I. were respectively 31 and 20, and in Class II. 25 and 16, in Group A the percentages in Class I. was 43 and in Class III. 52. In Group AB the percentages in all Turban's classes remained approximately the same; the figures, however, are necessarily small for this group. The authors regard these figures as showing a failure of resistance to tuberculous infection on the part of members of Group A. On this assumption an unduly high percentage of members of Group A should be found among the graver and a lower percentage among the milder cases of tuberculous infection. Since the mild and early cases are to be found attending dispensaries and the grave and late cases in hospital wards, the percentage of Group A patients should be lower among the former and higher among the latter class. This the authors found to be the case. Among the 300 cases in Group A 39 per cent. were ambulant and 54 per cent. warded in hospital; of Groups O and B, 32 and 20 per cent. respectively were attending dispensaries and 24 and 15 per cent. warded in hospital. Of members of Group AB the numbers warded and ambulant were about equal. The total number of cases investigated is too small to justify final conclusions, but so far as the investigation goes it seems to indicate a lack of resistance to tuberculous infection on the part of members of Group A. The few figures for Group AB suggest that this group, too, does not enjoy the resistance shown by Groups O and B. The implication of a genetic linkage of low immunity to tuberculous infection with the A agglutinogen is clear; confirmation of these results and further investigation as to whether the low immunity is special for tuberculous or general to all types of infection should follow.

THE MONKEY AS FRIEND AND ENEMY OF MAN

AN American advocate has recently argued that the theory of evolution gives the orang-utan a legal status but the learned judge disallowed the plea. The public health status of the anthropoid apes and monkeys has been almost as much neglected as their legal position. Although they are, in fact, our nearest relations, we have been far more friendly—as is so often found amongst relations—with remoter animals. The domesticated species have for long been studied and the diseases that they can convey to man, with or without suffering themselves, are fairly familiar. The Tropical Section of the Royal Society of Medicine remedied this omission last week when it held an inquiry into the danger to man of monkey diseases and infestations.

The obvious grouping for diseases of this kind is those from which both monkeys and man suffer, those peculiar to man but sometimes found accidentally in monkeys, and vice versa; and those which can be experimentally conveyed to monkeys from man although the animal is not naturally subject to them. The outstanding example of the first group is tuberculosis, and there is no doubt that in this case the greater sufferer is the monkey. There is no certain evidence that the animal in the wild state ever contracts the disease, but once it is captured, kept for awhile in the squalid conditions of a coast native hut, and shipped abroad, perhaps under shocking conditions of travel, the human bacillus plays havoc. Only the pathologist who has opened the body of a menagerie monkey can believe the extraordinary degree of dissemination that is seen. Some of the specimens brought from the Zoological Society's prosectorium by Col. A. E. Hamerton illustrated this very vividly. The bovine bacillus is equally virulent although there is less likelihood of exposure to infection. From the public health point of view, the pet monkey constitutes a danger to its owners unless its history from the time of captivity is above suspicion. The danger is increased by the extraordinary fact that a monkey riddled with tuberculosis may appear perfectly healthy until the day of its death. Monkeys in captivity are also susceptible to pneumococci and streptococci, and *B. aertrycke* and Flexner's bacilli have been isolated from the fæces. It is conceivable that they might act as carriers of pneumonia or dysentery if kept in close contact with man, but the risk is obviously not great. It seems probable that they may harbour the histolytic amœba without suffering from acute disease, and trypanosomes apparently identical with *T. gambiense* and *T. rhodesiense* have been found naturally in them. Our knowledge is, however, distinctly vague and uncertain until we come to helminthology. With Dr. T. W. Cameron's recent discovery of *Schistosoma mansoni* in the blood of African monkeys living in St. Kitts, a grave indictment has been brought against the monkey tribe. Bilharziasis is endemic in the West Indies and, so long as the monkeys carry the organism, the disease cannot be eradicated by measures directed against the human hosts alone. Dr. Cameron strongly suspects, also, that African monkeys in their native home carry *Schistosoma hæmatobium* as well as *S. mansoni*, and it would be well worth while for local investigators to confirm this. Whipworms, though common both to man and monkey, probably cause little disease, but the life-history of physaloptera requires further study as it has some local hygienic importance in Africa as it probably infests an intermediate host. The louse is a potential carrier of disease, and the human forms have a peculiar distribution among the great apes and the African spider-monkeys which might prove significant under certain circumstances. India, it must be remembered, has a peculiar problem of her own, since in many parts the langur or grey monkey is regarded as sacred and large numbers of semi-domesticated

acaques, or little brown monkeys, live in close ntact with the people. In India, every monkey sease is a potential danger to man in a way that it nnot be in countries where intimate contact is nfined to a few isolated pets. The general charge ainst the monkeys is, therefore, that they act as servoir hosts, certainly for bilharzia, and possibly r rabies, trichocephalus, and yellow fever.

The defending counsel would be able to put up a ry good case for the value of his client, the monkey, man. The whole tale of our research into and owledge of certain terrible diseases of man depends on the simple fact that they are transmissible to onkeys in the laboratory. Thousands of monkeys ve lost their lives from diseases which they would ver encounter naturally, in order to save mankind m the ravages of poliomyelitis and yellow fever, d even when the disease is one that other laboratory imals will take, the monkey is often preferable cause its illness more closely resembles that of man. of. E. Hindle declares that his work on yellow fever, e good results of which can hardly yet be estimated, as wholly based on the discovery that monkeys could infected. An interesting contribution to scientific owledge is offered by the study of monkey diseases d parasites. Dr. V. B. Wigglesworth pointed out at the distribution of lice has a definite phylogenetic gnificance and Dr. Cameron said the same of elminths. The parasitologist and epidemiologist ve a contribution to make to the study of evolution hich has hitherto been neglected. It may well prove ue also that the study of evolution and animal lationships would throw some light upon the stribution of disease and the lines along which it may expected to attack.

THE MECHANISM OF THYROID SECRETION.

THE results of some researches recently published y R. J. Ludford and W. Cramer[1] shed light on the fferences in the mechanism of secretion of the thyroid and in the normal gland and in exophthalmic goitre. ecent cytological work has shown that the products secretion in the thyroid cells accumulate in relation- ip to the Golgi apparatus which is normally situated etween the nucleus and the alveolar secreting surface the thyroid cell. During secretory activity droplets ppear in contact with the Golgi apparatus and pass it into the cytoplasm towards the lumen of the veolus. The position of the Golgi apparatus, herefore, gives a clue to the direction of the process of cretion. To exclude the possibility of a normal teration in position of the Golgi apparatus Ludford nd Cramer induced long and severe activity in the yroid cells of rats by exposing them to cold in an e-chest, sometimes after epilation. Sections of the yroid of rats so treated, although they showed some vidence of displacement of the Golgi apparatus in a w cells, showed no signs of definite double polarity. is concluded from this that in normal cells, even ter great secretory activity, there is no alteration in ie direction of the discharge of secretion. The osition of the Golgi apparatus was next studied in mouse that had spontaneously developed all the rdinal signs of exophthalmic goitre, and also in ands recovered from human beings with this disease. n the mouse the gland showed a remarkable deviation om the normal structure, especially as regards the olgi apparatus, which often exhibited a complete eversal of polarity, being directed towards the apillaries instead of towards the lumen of the alveolus. loreover, droplets of secretion could be seen in contact ith the Golgi apparatus of these displaced cells, a ndition not observed in normal over-stimulated lls that were a little displaced. A similar state of ings was observed in sections from the thyroid of uman exophthalmic goitre, except that droplets of cretion in contact with the Golgi apparatus were rely seen. The investigators attribute the absence f droplets to the fact that iodine had been given efore operation. They suggest that these findings dicate that in the normal thyroid gland the secretion passes into the alveolar lumen first, even during prolonged activity, and is then passed on into the blood; whereas in exophthalmic goitre the secretion goes directly into the capillaries. Thus the hormone that passes directly into the capillaries in exophthalmic goitre may be chemically different from that which in the normal gland only passes via the alveolus. This would coincide with views previously expressed that exophthalmic goitre is not due to an increased secretion of the thyroid gland, but to a slightly altered hormone.

THE DOCTOR AS PATIENT.

MUCH has been written about the psychological relation of the patient to his doctor, and the elements of it are well recognised. Its roots lie in that suggestibility which is prominent in the mentality of practically everyone, and which is, moreover, accentuated and focused by sickness until it dominates every other motive. All experienced clinicians know that the "confidence of the patient" may determine the success of the treatment, and the phenomenon has been further illuminated by the modern psychotherapists, whose object from the start is to secure a satisfactory "transference" of the unconscious infantile dependence of the patient to their own personality. What is not so often discussed is the manner in which this relation is modified when the patient is himself—or herself—a doctor. Prof. Theodor Brugsch [1] finds that the all-important element of confidence is practically annihilated. The doctor knows too much. He has reassured too many patients himself, he has too close an acquaintance with their minds and the irrational way in which it pays to deal with them to put any trust whatever in the method when applied to himself—and he assumes a priori that it will be applied to himself. The result is, says Prof. Brugsch, that a sick doctor is never the patient of the colleague who is treating him. He remains his own patient, unless the colleague is very strong-minded and eminent, or the sick doctor is too ill to criticise. The psychological rôles are reversed; the patient is the dominating partner and the physician the dominated, in proportion among other things to their relative ages. Moreover, as every doctor knows, an integral part of the treatment of many patients is the correction of false ideas about their condition. When the patient is a doctor his ideas are rather more erroneous, if anything, than they would be if he were a layman, and they are infinitely more troublesome to over-rule. If the colleague in charge is a younger man to do so may be impossible. Another factor which makes the treatment of a colleague difficult is the extreme reluctance of any doctor to admit that he is ill. The result is that he does not become a patient until he is so bad that he is the worst judge of his own condition, the more so since he had deceived himself about it from the beginning. Nevertheless, the fault is not all on the side of the patient. A great and very general mistake in the doctor who treats a colleague is, according to Prof. Brugsch, the assumption that the sick man must, because he is medical, be regarded as in some way different from an ordinary lay patient. The physician begins by making the cardinal blunder of taking his patient into consultation and treating him as a scientific equal. He assumes that his treatment must for this reason be instantly intelligible and acceptable, while from the nature of things it is most unlikely to be anything of the sort.

The conclusion Prof. Brugsch comes to is rather surprising. He does not suggest a remedy for this state of affairs except that both sides should recognise it and be on the look-out for its manifestations, and that the doctor who becomes ill should, as a doctor, forbear from treating himself but rather take the valuable opportunity of enlarging his knowledge of human nature by observing his own experience as a patient. What Prof. Brugsch does see in the situation is a reason for the almost universal custom of refusing to take a fee for services to a medical colleague.

THE CHLORINE TREATMENT OF DRINKING WATER.

NASCENT oxygen has proved to be so truculent an enemy of bacterial life that it may come to be regarded as one of mankind's chief aids in his struggle with the lower fungi. The potency of oxygen as elaborated from water by the action of chlorine or its compounds is not determined by its concentration as in the case of mere chemical disinfectants, for the onslaught on bacterial life continues unabated until the last molecule of oxygen has disappeared, while after disinfection is complete there is no poisonous or unpleasant remainder except it may be in the case of certain trade effluents. Hence it is that the use of chlorine for water purification is gaining in popularity every year.

It was at Lincoln in 1905 that Sir Alexander Houston first used an alkaline hypochlorite solution, containing 12 to 14 per cent. of available chlorine, to sanify the drinking water in the face of an emergency created by an epidemic of typhoid. Chlorination was adopted during the late war as an interim measure for London river water and has never been discontinued. Now in many parts of Europe, Asia, and America chlorinators have been installed on a large scale. Quite recently, for instance, the water-supply of Santiago (Chili) has been disinfected with, it seems, an immediate decrease in the rate of infant mortality. In Bogotá (Colombia) typhoid fever diminished rapidly as soon as the aqueduct water was chlorinated. In the United States of America 70 per cent. of the population are supplied with drinking water that has been treated with chlorine. The procedure varies from place to place. In some a minimal amount of chlorine is merely added to the clear and colourless filtered water as a final safeguard against accidental contamination during distribution. In others the chlorine is introduced to the raw water prior to filtration. In yet others a large excess of chlorine is added to destroy algæ as well as bacteria, the excess being subsequently removed by treatment with some other chemical agent such as sulphur dioxide. There has been similar variety as to the form in which the chlorine is presented. On the largest scale chlorine gas compressed into liquid form is the simplest and most effective form of chlorination. In Central and South America, as well as in other countries at a distance from places where liquid chlorine is manufactured, the product resulting from the electrolysis of sea-water has been used as a substitute; while in France resort has naturally been taken to the hypochlorite solution known as *eau de Javel*, which has long been in use as a cheap and harmless disinfectant in the home. On another page Mr. T. H. Bishop describes a simple but very ingenious apparatus for the *javelisation* of drinking water as it is practised in Rheims. This apparatus, as the illustration shows, does not involve the use of anything except the simplest material and a primitive type of installation. Another simple form of apparatus for the same purpose has been recently described [1] by Major E. W. Wade, R.A.M.C., the mother type of all these apparatus being that set out by Houston in the sixteenth annual report of the Metropolitan Water Board.

On active service the conditions are very different, and any feasible method of preparing potable water implies the use of some compound containing positive chlorine which is solid at ordinary temperatures and pressures. Bleaching-powder, however cheap and accessible, has proved too erratic in use as a water disinfectant; chloramine and halazone, which have been tried abroad, act too slowly to be safe in emergency. In a recent number (October, 1928) of the *Military Surgeon* Major Cyrus B. Wood, of the U.S. Army Medical Corps, makes a strong claim for succinchlorimide as a chemical agent for the preparation of potable water. This is a colourless crystalline compound with a slight chlorous odour, a melting-point of 148° C., readily soluble in one hundred parts of water. It seems to possess the qualities of a useful water steriliser—namely, prompt reaction, stability on prolonged storage, and non-toxicity towards the human body. Its stability is such that, on exposure to air and light (other than direct sunshine) at 50 per cent. humidity for 50 days, succinchlorimide only lost 0·78 per cent. of its original chlorine, while halazone lost 1·7 and bleaching-powder 22·8. Major Wood concludes that succinchlorimide is a compound suitable for the preparation of small quantities of potable water.

[1] Jour. R.A.M.C., October, 1928.

AT the Royal College of Physicians of London, Pall Mall East, the Milroy Lectures will be delivered by Dr. J. Graham Forbes on Feb. 26th, 28th, and March 5th; his subject will be Past and Present Diphtheria in England and Wales, with special reference to the London Metropolis. On March 7th, 12th, and 14th Prof. E. B. Verney will give three Goulstonian Lectures on Polyuria. The Lumleian Lectures on March 19th, 21st and 26th will be a Medical Review of the Surgery of the Chest by Dr. R. A. Young. Dr. F. M. R. Walshe will deal on April 30th and May 2nd in his Oliver-Sharpey Lectures with the Physiological Analysis of some clinically observed Disorders of Movement. The Croonian Lectures will be delivered on June 4th, 6th, and 11th by Dr. H. H. Dale, F.R.S., who has chosen as his subject Some Chemical Factors in the Control of the Circulation. The time in every case is 5 P.M., and any member of the medical profession will be admitted on presentation of a visiting card.

Lord Beaverbrook's recent gift of £22,800 for medical education has been allocated by the Prime Minister to the following institutions: The Royal Society of Medicine, £2800; the Royal College of Physicians, the Royal College of Surgeons, the Medical Faculties of the Universities of Oxford, Cambridge, London, Durham, Manchester, Birmingham, Liverpool, Leeds, Sheffield, Bristol, St. Andrew's, Glasgow, Aberdeen, Edinburgh, and Wales, the Cancer Hospital, Epsom College, and Queen Charlotte's Hospital National Mother-Saving Campaign, £1000 each. The grant to be applied for special purposes beyond the capacity of the ordinary income of the institution—e.g., on studentships, research, or contributions to scientific equipment.

Two anonymous donors have each given a gramme of radium to the London Hospital. One of them, who previously gave £50,000 to endow the hospital's Freedom Research Fund, has also given a further £13,000 to establish and maintain a laboratory for the production of radon, this work being carried out under the name of the Freedom Radium Fund. The cost of one gramme is about £12,000.

THE Royal Free Hospital, London, has received from its chairman, Mr. Albert Levy, the sum of £50,000 as a contribution to the fund for rebuilding the hospital's maternity department, and for research into the causes of maternal mortality and of invalidity.

CUMBERLAND COUNTY HOSPITAL.—The new out-patients' wing of the Cumberland County Hospital was opened on Feb. 7th by Mr. Theodore Carr, on the occasion of the centenary of the foundation of the institution. The new wing cost £33,000, and is part of a general scheme costing £70,000.

SUSSEX PROVIDENT SCHEME.—The prediction made in 1921, when the late Dr. J. F. Gordon Dill launched this scheme for hospital and specialised medical services, that in a very few years it would benefit the hospitals to the extent of £10,000 a year, has been more than fulfilled. In 1928 the coöperating hospitals received no less a sum than £11,142. The largest payment during that year was £4286 to the Royal Sussex County Hospital, Brighton, whilst the Royal Alexandra Hospital for Sick Children received £1628, and the New Sussex Hospital for Women and Children £1260. The sum of £850 was paid to the Hove Hospital, and three other institutions received over £500 each.

The Clinical Interpretation of Aids to Diagnosis.

Series of Special Articles contributed by Invitation.

XII.—THE CLINICAL SIGNIFICANCE OF THE BLOOD-UREA CONTENT.

THE estimation of the blood-urea has become a commonplace of ward work with the advent of methods which permit the utilisation of small quantities of blood but yield accurate results. It has indeed long been recognised that urea accumulates in the blood in certain types of renal disease, but the large quantity of blood needed and the labour involved militated against the use of routine estimations of the blood-urea in clinical medicine. It is not proposed to discuss in detail the numerous methods of urea estimation which are now employed, but it may be mentioned that they are of two main types. In the first, which was used by Widal in his classic work on renal disease, hypobromite is added to the deproteinised blood and the nitrogen evolved is estimated: in the second, which we owe to Marshall, Folin, and Van Slyke, the urea is decomposed either by the ferment urease or by the autoclave, and the ammonia formed estimated colorimetrically after Nesslerisation or by volumetric titration after distillation into acid.

The Normal Blood-urea.

Before considering the clinical significance of the urea content of the blood, it is necessary to form some idea of the factors which in health maintain it at a fairly constant level. We have on the one side the formation of urea in the katabolism of proteins; on the other, the excretion of urea by the kidneys. The blood-urea content represents a balance between these two activities. Let us first consider the activity of the kidney.

No evidence has been adduced which suggests that urea is treated by the kidney as a threshold substance. While such useful bodies as sugar or sodium chloride are conserved, and not excreted by the kidney unless their concentration in the blood exceeds a certain threshold value, urea is, from the kidney standpoint, a purely waste body to be excreted however low the blood-urea content. It is not, apparently, a function of the kidney to maintain the blood level at a "normal" level. Since, however, the rate of excretion of urea tends to bear a direct relationship to the concentration of urea in the blood, with a healthy kidney and an average diet, the blood-urea content tends to remain within certain definite limits. A further point of great practical importance is that adequate water must be available for excretion if the blood-urea is to be kept within these limits. If, for instance, we assume that 30 grammes of urea are being formed in the body daily, and that the kidney can concentrate urea in the urine to the high figure of 5 per cent., it is obvious that 600 c.cm. (20 oz.) of urine at least must be excreted per diem if a balance is to be struck between urea formation and excretion. If less water than this is available, urea will accumulate in the body and the blood-urea will rise.

The effect of the diet on the blood-urea is not of any great importance from the point of view of the clinician. It is true that, even in healthy persons, by raising or lowering the protein intake the blood level may be raised to a level of 50 mg. or dropped to as low a figure as 12 mg. per 100 c.cm., but such variations are not seen on anything approaching an average diet. The only variation commonly met with, which may reasonably be attributed to an alteration in the amount of urea formed in the body, is the low blood-urea of the later months of pregnancy. The blood-urea of the pregnant woman may fall to as low a level as 10 mg. per 100 c.cm., probably owing to the demands of the growing fœtus on the protein of the maternal diet. The above points have merely been emphasised in order to draw attention to the fact that causes outside the kidney may lead to alterations in the blood-urea content. One further important consideration must be mentioned—the large factor of safety in the renal tissue available. So large is the excess of kidney substance over the necessary minimum that one kidney suffices to ensure adequate urea excretion. The blood-urea does not therefore rise after a unilateral nephrectomy.

In hospital patients on an ordinary ward diet the blood-urea content will usually be found to lie between 20 and 40 mg. per 100 c.cm (0·02 to 0·04 per cent.); in strictly healthy young adults in a fasting state between 20 to 30 mg. For our purpose we may regard any figures over 40 mg. as excessive.

Uses of the Blood-urea Estimation in Clinical Work.

Blood-urea estimations are employed by the clinician in the diagnosis and prognosis of nephritis in the examination of patients suffering from surgical affections of the urinary tract, and, lastly, in the diagnosis of uræmia from other conditions. Under this last heading we have to consider possible extra-renal causes of urea retention. Let us first discuss the question of nephritis, assuming that our patient shows symptoms suggestive of that disease, and that his urine contains albumin and casts. Under such conditions any urea accumulation found may fairly be attributed to renal inadequacy.

The Blood-urea in Nephritis.

The two main types of renal inadequacy were first differentiated by Widal, and are too well known to need elaboration here. Suffice it to say that in the first, or azotæmic, retention of urea and other waste nitrogenous bodies is present, while in the second, or hydræmic, water retention, without appreciable accumulation of urea in the blood, is the main feature of the disease. We are concerned here with the first of these two forms of renal failure, but it may be mentioned that in the hydræmic patient a moderate increase in the blood urea, to such a figure as 50 mg., may be found. Such accumulations are merely the result of the oliguria, the concentrating power of the kidney remaining intact and the percentage of urea in the urine high. The azotæmic form of renal inadequacy on the other hand is characterised by an absolute inability to excrete a concentrated urine. The main forms of renal disease in which this inability to concentrate and excrete urea is present are chronic interstitial nephritis, acute and subacute glomerulo-nephritis, pyelonephritis, and polycystic kidney. In assessing the significance of any blood-urea figures found, it is, in the first place, absolutely essential to arrive at an idea of the type of disease present. In interstitial nephritis and polycystic kidney we are dealing with steadily but slowly progressive lesions, in acute glomerulonephritis with a disease in which very rapid changes for better or for worse are possible, and in pyelonephritis with a lesion capable of rapid extension. It is in the relatively stable conditions first mentioned that the estimation of the blood-urea is of most value. The laboratory worker, if asked for his opinion as to the significance of the figures found, is entitled to all available information as to the pathological condition present.

In drawing conclusions from the blood-urea content in cases of acute glomerulonephritis certain considerations must be kept in mind. In the first place, extreme oliguria is usually present, and the rise in the blood-urea may be due as much to inadequate water excretion as to impaired concentrating capacity. Secondly, rapid improvement and a sudden diuresis may set in at any time. As a result, prognosis based on the blood-urea content is far from certain. It is in this disease, especially in childhood, when extraordinary reparative capacity is present, that we see the highest blood-urea accumulations followed by recovery. As a rule, a blood-urea content above 300 mg. indicates a

fatal result, but recovery may occur even though a level of 400 mg. has been reached.

It is in interstitial nephritis and in the polycystic kidney that the blood-urea estimation finds its most valuable clinical application. Polyuria is the rule in these conditions, urea excretion is not therefore hampered by inadequate passage of water, and the blood-urea gives a true picture of the state of the renal function. The presence of albumin and casts in the urine of a middle-aged man, associated with a raised blood pressure, does not necessarily imply gross functional damage to the kidney. It is not unusual to see cases of hypertension in which dyspnœa and œdema, actually cardiac in origin, have been attributed to renal failure and regarded too pessimistically, while one also frequently meets with patients in whom, owing to absence of blood analysis, symptoms have been misinterpreted which should have served to indicate the imminence of a fatal uræmia. Lastly, chronic interstitial nephritis is a disease in which the renal function tends to slowly and steadily deteriorate, and in which the course, apart from certain accidents, can be fairly accurately prognosed. The rules of prognosis, laid down by Widal for these cases, seem to me to be still valid. With a blood-urea above 100 mg. life is rarely prolonged for more than two years, with a blood-urea above 200 mg. death may be expected within six months, while minor accumulations up to 100 mg. are of no prognostic significance. It is advisable to base one's decision on two estimations, made at intervals of about a month, if one wishes to avoid mistakes due to temporary exacerbations, and to form some idea of the rate of progress of the disease.

Retention of Other Nitrogenous Waste Bodies in Renal Disease.

Creatinine.—In estimating urea we are not estimating a body which is in itself toxic and which will infallibly kill our patient when it reaches a certain level in the blood. We are merely using the accumulation of a waste product in the blood as a measure of the degree of renal inadequacy. Now, since the amount of urea formed varies with the protein content of the diet, the load of urea presented to the damaged kidney for excretion is very far from being a fixed quantity in different individuals or in the same individual from day to day. Of all the nitrogenous waste bodies present in the urine, creatinine shows the most constant daily excretion on a creatinine-free diet. The blood creatinine content has therefore been suggested as a more satisfactory index to the degree of renal inadequacy present than the urea content. Creatinine accumulates in the same types of renal disease as does urea and has been found to possess a very considerable prognostic significance. A creatinine content in excess of 5 mg. (normal 1·2 to 1·5 mg.) indicates in chronic nephritis that death will take place within a year.

Uric Acid.—For the third nitrogenous waste body, uric acid, a different significance is claimed. It, too, accumulates in the blood of the interstitial nephritic, and it is contended that of these bodies it is the one which is concentrated by the kidney from blood to urine with most difficulty. According to some authors, therefore, uric acid will tend to bank up in the blood at a stage of the disease at which urea is still satisfactorily excreted, and an excess of uric acid will be the first indication of renal failure. Actually it would seem doubtful whether estimations of these two bodies add appreciably to the information which may be derived from the simpler blood-urea determination.

The Blood-urea in Urinary Surgery.

Since one intact kidney amply suffices to keep the blood-urea within normal limits, it follows that an increase in the blood-urea above the normal figure indicates an affection involving both kidneys. This rule finds a certain surgical application in renal tuberculosis or calculous pyelitis, but the relative efficiency of the two kidneys is more satisfactorily studied by ureteric catheterisation after administering a dose of 15 grammes of urea. Under these conditions a urinary urea concentration of 2 per cent. and upwards during the second hour may be taken as indicating an adequate efficiency in the secreting kidney.

The blood-urea examination is of more value in prostatic disease in which any renal damage present is bilateral. In the prostatic case we have two main renal conditions to consider; in the first place, the interstitial nephritis which follows long-continued obstruction, in the second, pyelonephritis. Of the possibility of the sudden onset of the latter, blood-urea estimations can, of course, give us no warning though they may indicate the existence of the former. It is generally accepted that with a blood-urea above 50 mg. the state of the kidney is such as to indicate caution in surgical interference, that is, a two-stage operation. Further estimations after the first stage will indicate any renal improvement and the time at which removal of the prostate may be undertaken.

Extrarenal Causes of Urea Retention.

Up to this point we have dealt with accumulations of urea in the blood of patients in whom the diagnosis is established. We have assumed that the patient suffers from some renal lesion in which failure of urea excretion is known to occur and have tried to assess the value of the findings as a guide to prognosis or treatment. Let us now consider the case of the patient in whom the diagnosis is in doubt and in whom a blood-urea estimation has been made as part of the routine examination. Let us suppose that the blood-urea content has been found to be above 100 mg. per 100 c.cm. Are we at once to assume that we are dealing with a case of serious renal impairment, and to plan treatment accordingly? The answer is emphatically in the negative, since in several conditions which may clinically suggest uræmia a high blood-urea may be met with though actually the kidneys are intact. We may, for instance, be called to a patient in middle life suffering from incessant vomiting with a trace of albumin in the urine. We find this blood-urea content to be 100 mg. per 100 c.cm. and diagnose uræmia, only to discover later that he is actually suffering from intestinal obstruction.

Desiccation Urea Retention.—There are, in fact, a whole series of conditions in which inadequate water is available for excretion of urea and in which the blood urea reaches a high level as the result, even though no renal lesion is present. The rise in the blood-urea is favoured by the fact that desiccation in itself leads to excess in katabolism of protein and to excessive urea function. The unfortunate kidney is thus faced with an added demand on its excretory functions at the very time at which it is least able to meet it owing to an inadequate supply of water for excretion. Among instances of such "desiccation," urea retention one may mention intestinal obstruction, general peritonitis, diabetic coma, gastro-enteritis in childhood and cholera. Very high blood-urea contents may also be seen in comatose patients whose fluid supply has been inadequate.

Though at first sight it might seem that such accumulations must lead to hopeless confusion, this is not actually the case. Retention of urea due to actual renal lesions is always accompanied by inability of the kidney to concentrate. In the "desiccation" retentions the concentrating faculty remains good and if a specimen of the urine is obtained it will be found to show a urea concentration of 3 per cent. and upwards. By a simple hypobromite estimation of the urinary urea we can therefore pick out this group from the true uræmics. The indication is, of course, to to supply fluid by any possible route, since in addition to urea other waste bodies are retained and an acidosis similar to that of uræmia develops. Similar but smaller accumulations may be met with in cardiac disease with decompensation and oliguria—such figures as 50 to 60 mg. being not uncommon.

In cases, therefore, in which the blood-urea has been estimated as a diagnostic procedure and found to be above the normal upper limit of 40 mg., it is advisable

t to be content with this finding alone, but to ntrol the conclusions drawn from it by an estimation the concentration of urea in the patient's urine. It hardly necessary to add that the ordinary clinical amination for albumin, casts, &c., must not be nitted. In the presence of a high blood-urea and a w urinary urea concentration, the physician may st assured that he is dealing with true renal adequacy. If these considerations are borne in nd, the blood-urea estimation is as valuable an aid the diagnosis of certain obscure cases as it is the prognosis of chronic nephritis.

ADENOIDS AND ENLARGED TONSILS.

INTERIM REPORT BY THE BOARD OF EDUCATION'S MEDICAL COMMITTEE.

IN 1924 Sir George Newman arranged for four mall medical committees, consisting of officers of e medical branch of the Board of Education with nical experts and representative school medical ficers, to consider four subjects requiring further vestigation in order to enable the Board and the edical officers of the local education authorities to rform their duties more effectually. The committees were to be of an informal nature and form rt of the scheme for "field" research into those pects of the work of the school medical service cluding the abnormal child) on which knowledge is inadequate. The subjects to be dealt with by is means were (*a*) the prevention of adenoids and larged tonsils, (*b*) the prevention of defective vision d squint, (*d*) an anthropometric survey of a large oup of children of school age, and (*d*) the problems esented by the mentally defective child.

The Committee and its Reference.

The first of these committees, which has now esented an interim report,[1] consisted of Sir George ewman, chairman; Dr. R. H. Crowley (Board of ducation), vice-chairman; Dr. D. Forsyth (physician, aring Cross Hospital); Mr. H. Bell Tawse (aural rgeon, Nottingham Education Committee); Dr. J. Thomas (senior medical officer, L.C.C.); Mr. . Tilley (surgeon to ear and throat department, niversity College Hospital); Dr. A. Warner (school edical officer, Leicester); with Dr. H. C. T. Langdon Board of Education), secretary. This committee was ked to inquire into the incidence of, and physical d environmental conditions associated with, enlarged nsils and adenoids, and into the methods and results treatment.

The Ætiological Problem.

The Committee's investigation revealed no dramatic fference in the social circumstances or environment children suffering from enlarged tonsils and adenoids compared with other children. The evidence so r accumulated suggests that the ætiological problem similar in some respects to that of dental disease, that both conditions affect all classes of society ithout any conspicuous difference in incidence; at there is a definite tendency for certain families be affected; and that the cause in a considerable mber of cases obviously begins to act in antenatal early postnatal life. The report adds that the equent association of these two conditions suggests ther that the one affects the other, or that there is common cause, or both.

[1] Board of Education. Interim Report of the Medical ommittee on Adenoids and Enlarged Tonsils. H.M. tationery Office. 1929. 6*d*.

The antenatal and early postnatal history of these cases indicates that they start life with a slight but perceptible handicap. Prematurity, artificial feeding, defects of environment are slightly but consistently commoner than among normal children. The onset of adenoids appears to be preceded by catarrhal affections of the nasal passages. These attacks may be due to an abnormal susceptibility of the mucous membranes during the first years of life, the result perhaps of a lowered vitality, the causes of which have not yet been made clear. Alternatively they may follow a chance infection of normal mucous membranes, a possibility indicated by the very considerable proportion of cases in which an attack of infectious disease is the immediate precursor of adenoids. The apparent association of enlarged tonsils and adenoids with rickets suggests the possibility that a deficiency of the calcifying vitamin D may play some part in the ætiology of this condition. This is a matter which in the opinion of the Committee deserves careful investigation.

There are two lines of investigation which should go far in the Committee's opinion towards settling this matter. One, carefully controlled, should be carried out on similar lines to that already done by Dr. G. C. M. M'Gonigle, in order to check his results, and to determine whether the slighter signs of rickets are generally present with enlarged tonsils and adenoids; the other should be directed to ascertaining whether an adequate supply of the calcifying vitamin from the earliest years of life tends to prevent the onset of adenoids. An investigation on these lines having reference to the origin of dental disease is actually in progress at certain institutions in Birmingham under the auspices of the Medical Research Council, certain groups of children being supplied regularly with an additional amount of the calcifying vitamin, while others similarly circumstanced remain on the standard diet.

The fact is emphasised that adenoids may occur as early as the first year of life, that they seldom develop after the eighth year, and in the majority of cases are already established by the fifth year. The investigation as hitherto conducted has suffered from the disadvantage that the great majority of the children when first examined had already passed the age of onset; there were thus only a small number in whom it was possible to watch the early development of the condition. Moreover, with these children it has been necessary to rely upon the uncertain memory of parents for information of the highest importance concerning the diet, habits, and ailments of the children. For the proper study of the antecedent signs and symptoms it would be necessary to recommence at an earlier age—in fact to follow up a series of children from birth. Such an investigation would most easily be conducted at infant welfare centres, where the child's history could be recorded from month to month; only by such means can it be hoped to obtain reliable information as to feeding, ailments, habits, environment, and dental condition. In any such future inquiry it should be realised from the outset that enlarged tonsils may exist independently of adenoids (some of these cases showing little or no special tendency to develop adenoids) and equally that adenoids may occur unassociated with tonsils. Dissimilar causes may therefore be responsible for the two conditions.

Relationship to Dental Disease.

A definite relationship appears in the light of the Committee's investigation to exist between dental disease and the presence of enlarged tonsils and adenoids, but the nature of this relationship has not so far been established. It is conceivable either that the presence of septic teeth is a factor in the production of tonsils and adenoids, or that the mouth-breathing of adenoids predisposes to dental decay, or that both conditions have a common origin. Some light would be thrown on this question by the careful observation (*a*) of the effect of complete dental treatment on the tonsils and adenoids, and (*b*) of the effect on the dental

condition of removing the tonsils or adenoids. The Committee suggest that both these investigations could be carried out by school medical officers and school dentists without any greater difficulty than is involved in careful observation and recording. A delay of a few months before operating in order to test the value of dental treatment might possibly lead to important results.

Spontaneous Cure or Operation?

The after-history of the cases under review shows a tendency to spontaneous cure of a limited number, and that the cure, when it takes place, may provide as favourable a change in the general condition as is effected by operation. Nevertheless, in the experience of the Committee, the great majority persist unchanged for a considerable period, if indeed they do not get worse. Educational retardation is a fairly common result of adenoids, especially in the higher age-groups. The cause in a certain number of cases is the defective hearing which so often accompanies this condition; in others there is a certain mental lethargy which may be due to some interference with the cerebral circulation. Whether intelligence as measured by the usual tests is actually lower than normal does not seem to have been determined. This is a point worth investigating, particularly by a series of such tests to ascertain whether any improvement in the intelligence quotient results from the removal of the adenoids.

The immediate results of operation are shown to be favourable in the great majority of cases, but less so in regard to aural symptoms than to those of the nasopharynx. There is a small amount of evidence which suggests that the improvement in some children is not maintained. The Committee consider that some further inquiry should be pursued to determine whether this is in fact the case, and if so what are the probable causes. The question of recrudescence of adenoids after operation has not come within the scope of this investigation.

Two Further Investigations.

The Committee's report closes with an announcement of their decision to proceed with further investigations on the following lines: (1) The systematic examination of a series of unselected children from birth, in order to ascertain the facts in the early history and condition of these children which are associated with the onset of enlarged tonsils and adenoids. The examinations will include detailed inquiry into the maternal history during pregnancy and the dietary of the child during its early life, as well as a careful record of the dental condition, including the period of eruption, structure and arrangement of the teeth, the occurrence of caries, and the condition as regards oral sepsis. Any signs suggestive of rickets will be carefully noted. (2) The examination of a large number of unselected children at 5 years of age in order to ascertain the frequency of association of certain bony abnormalities suggestive of vitamin deficiency, with enlarged tonsils and adenoids.

MEDICINE AND THE LAW.

Certification Without Attendance.

AT an inquest at Walthamstow a fortnight ago upon a boy, aged 10, who had died from diphtheria, it appeared that a woman doctor had, on statements from the boy's mother and without personally seeing the boy, certified that he was suffering from influenza and unable to attend school. Questioned by the coroner, the doctor stated that she had not done such a thing in any other case, and did so here only because the mother was in such difficulties. It further appeared that the doctor had, again on the mother's statements and without seeing the boy, prescribed a tonic for him. In the course of recording a verdict in accordance with the medical evidence, the coroner remarked on the procedure by which anyone could seemingly go to a doctor and obtain an indefinite medicine called a tonic without the actual patient being seen; the consequence was, he said, in this particular case, that the mother assumed that the doctor had undertaken the treatment of the child; the child had remained at home seriously ill and a source of infection, and had gradually become worse and died.

Comments by coroners upon doctors obtain such prominence and publicity that it may sometimes be necessary to remember that the doctor has not always either received notice of impending criticisms or been allowed an adequate opportunity of reply; occasionally, too, the matter which gives rise to the comments is something rather remote from the actual cause of death which the inquest is investigating. Subject, however, to these cautious reservations, the incident would seem to invite attention to the necessity of strict care in the giving of certificates. The General Medical Council's "Warning Notice," it will be recalled, observes that any registered medical practitioner shown to have signed a certificate which is "untrue, misleading, or improper," is liable to have his name erased from the Medical Register. A certificate to excuse a child's absence from school is not one of the most important of documents, and agitated parents may by their importunity harass busy practitioners; but the whole profession suffers when a coroner has an opportunity to find fault as at Walthamstow. The wide powers of certification which the profession is allowed cannot be defended if carelessly applied.

Neurasthenia and Workmen's Compensation.

The legal relation of neurasthenia to personal injury is one of the most awkward questions for a judge, especially when he cannot transfer to a jury the task of assessing the financial consequences. In a recent Bristol case the county court judge made it clear that he had been guided largely by the opinion of his medical assessor. The applicant, a married woman, aged 63, with four children, had for a long time been in a position as domestic servant. One day she fell from some steps, the physical damage being slight but the mental result considerable. For some two months she received compensation at the rate of 15*s.* 9*d.* a week; then a medical certificate was given to the effect that the incapacity had ceased to be due to the fall from the steps and was now attributable to the recurrence of a previous nervous breakdown. The applicant claimed her condition was due to the accident; witnesses gave evidence that she had always suffered with her nerves but had not actually had a nervous breakdown before; it was said that she was worse since the accident, and had naturally worried herself over the termination of her award. A medical witness for the applicant said that, although work might take her mind off her worries, she was not fit to do work involving mental concentration. For the employer it was said, on the other hand, that the woman's state was a distinct type of neurasthenia not caused by her fall from the steps. The judge held that her condition was the result of the accident but that she was not wholly incapacitated. He estimated her to be capable of doing at least two half-days' work a week (with an earning value of 5*s.*), and awarded compensation (with costs) on the basis of such partial incapacity. These, of course, are cases in which there is more fact than law to decide, but they are none the easier on that account.

KING'S COLLEGE HOSPITAL.—On Thursday last week Princess Marie Louise, acting for the Duchess of York, opened the Wigram Ward for children at this hospital and received purses for the endowment of one of its cots named after Princess Elizabeth. Sir Lenthal Cheatle, chairman of the Medical Board, stated that this is the first time that a ward has been founded devoted entirely to children needing surgical treatment. The ward contains 24 beds, all of which are full. Nearly one-half of them are given up to throat cases, which will obviate sending patients home immediately after operation on the tonsils. The ward formerly available for children will now be used for medical cases only.

HOSPITALS AND THE RATES.

PRESENT POSITION OF PROVINCIAL VOLUNTARY HOSPITALS.

A MEMORANDUM [1] issued by the Central Bureau of ospital Information owes its origin to inquiries from ıe chairmen and secretaries of hospitals regarding the ɔsition generally with reference to assessments now ɛing made under the Rating and Valuation Act, 1925, ıd the prospect of any action of a joint character ɛing taken. A questionaire was sent out on ov. 28th, 1928, to 679 provincial hospitals in England ıd Wales. By Dec. 31st replies were received from 21 hospitals, containing 18,339 beds (45 per cent. the total). In a large number of places the figures the revised assessment have not yet been determined ıd many hospitals hesitate to express a decided ɔinion with regard to joint action until they know :actly what their own position might be.

The summarised replies provide a basis large enough justify an attempt to form estimates regarding the),285 beds in the English and Welsh provincial ɔspitals. These are: (1) That the English and 'elsh provincial hospitals prior to revision were ıssessed at £63,000, or £1·56 per patient bed. (2) That ıe revised assessments of these hospitals under the ct of 1925 will amount to £95,000, or £2·36 per ıtient bed. (3) That these hospitals which, prior to vision, paid £44,000 annually in rates will, after vision, be called upon to pay £66,000. (In a atement issued by the Ministry of Health it is timated that the average amount of local rates vied for the year 1927–28 was 13*s.* 8¼*d.* in the £ of ıssessable value.)

The views of the 221 hospitals regarding joint :tion are set forth in the following summary :—

	Number reviewed.	
	Hospitals.	Beds for patients and percentage of total.
ɔspitals in favour of joint action with a view to obtaining de-rating ..	107	9,567 (52·17)
ɔspitals in favour of joint action with a view to obtaining assessment on a preferential and uniform basis	60	4,623 (25·17)
ɔspitals which did not express any opinion on the subject	51	3,947 (21·52)
ɔspitals which definitely oppose joint action ..	3	202 (1·10)
	221	18,339

The financial effect of de-rating would be to relieve ıe provincial voluntary hospitals of an annual ayment of approximately £66,000. With regard to ıe financial effect of assessment upon a preferential ıd uniform basis, an examination of the tables ıggests that if the hospitals therein detailed can be ɔnsidered as a representative portion of the whole, ıses of 5*s.*, 10*s.*, and £1 per patient bed would ıcrease the rates payable as follows :—

nount of assessment per patient bed.	Percentage of hospitals where an increased amount would be payable for rates.	Percentage of total number of beds in the provincial voluntary hospitals.
5*s.*	6	4
10*s.*	13	8
£1	19	12

The memorandum is signed by Mr. R. H. P. Orde irector) and Mr. F. C. Davies (secretary), who ɔnclude with the remark that the available data ırdly justify further deduction than they have made.

[1] Memorandum No. 6, obtainable from the Secretary of the ıreau, 19, Berkeley-street, London, W.1. Single copies, . post free. 12 copies, 2*s.* 6*d.*

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Influenza in Berlin.

THE pandemic of influenza which has now reached Berlin is apparently of a benign character, although lately more cases complicated with pneumonia have been reported. The epidemic began as early as December, 1928, but in the first few days of this year there was an explosive increase. On Jan. 4th, 1409 cases were notified to the Berlin general sick-club, which has about 500,000 members. There was at first some difficulty in finding room for the patients, as the hospitals were soon overcrowded, but the Municipal Health Office took the necessary measures. They lent from the Red Cross department 13 barracks with 200 beds, and 46 transportable huts held in reserve for special emergencies were taken into use; the new St. Joseph Hospital belonging to the Roman Catholic Order of the Grey Sisters, which was not to have been opened for several weeks, was made ready by working day and night, and its 600 beds were soon occupied. Some schools where a great number of pupils were ill had to be closed, and the school-rooms adapted as temporary hospitals. A drawback was that a large number of the nursing staff had caught the disease, so that a deficiency of nurses arose. The Health Office has appealed to retired nurses and voluntary Red Cross sisters to do temporary service in the hospitals, and the staff has been replenished in this way. The daily average number of new cases has not increased for some days, but remains at the same level. Children seem to be more liable to catch the disease this year than in former epidemics.

Foreign Guests of the Berlin Medical Society.

Two foreign guests, Prof. Claude Regaud from Paris and Dr. R. G. Canti from London, read papers before the Berlin Medical Society on the cancer question. Prof. Regaud gave in excellent German a report of the success obtained by radium treatment. He explained the different methods of radium administration, especially the method where needles impregnated with radio-active substance are placed round or into a malignant growth and left there for six to eight days. In cancer of the skin he attaches the radio-active tubes by means of a plastic wax mask, adapted to the respective part of the body. These masks are borne by the patients for some days without doing any harm. The results are excellent. In Prof. Regaud's hands 80 out of 344 patients with cancer of the tongue—i.e., 23 per cent.—were definitely cured; in 20 per cent. recurrence took place in neighbouring glands, and in 20 per cent. the treatment was ineffective. In cancer of the lips the results were still more favourable, as a cure was obtained in 90 per cent. of operable cases, whilst of 28 inoperable cases four were restored to health. In cancer of the cervix uteri the number of cures has increased from year to year. Dr. R. G. Canti, of St. Bartholomew's Hospital, London, showed his cinematographic demonstration of living cells, normal and malignant, cultivated in vitro, and of the action of radium on their growth. After the meeting the guests were entertained at a banquet which was attended by many members of the society and of the German Cancer Committee, and by representatives of the Health Office.

Gymnastics for School-children.

Dr. Schlesinger recently described to the Frankfort Medical Society researches on the influence of gymnastics on the physiological functions of school-children. 300 boys and girls from 10–17 years of age were examined before and after a gymnastic lesson. It was stated that in one-quarter of the boys and in one-sixth of the girls a marked increase of the dynamometric index was obtained, a proof that the mental rest had been stronger than the bodily

exertion; on the other hand, in one-third of the boys and in two-fifths of the girls the dynamometer showed a decrease of strength, which was especially noticeable in the weaker children, in fat children, and in those with anomalies of the cardiac function. After a long run, blood pressure was increased for about three minutes, but in the succeeding 15 minutes the pressure dropped to below the normal value. Forty per cent. of the children show a decrease of temperature in the axilla. Researches were further carried out in 250 school-children especially devoted to sport, in comparison with others who did only the prescribed gymnastic exercises or took no bodily exercise at all. It was ascertained that the size was but little influenced, but that the weight was increased by the stimulation of metabolism, and so were the spirometric and dynamometric index respectively. The examination of boys of 16–18 years of age who had gone through a short intensive course of training showed that the majority had an increase of weight and of hæmoglobin content of the blood, but a decrease of the spirometric and dynamometric index produced by latent fatigue due to over-exertion. Over-exertion of the heart was observed only when exercises had been performed without supervision.

Complaints by Dermatologists.

The dermatological and venereal section of the Berlin Medical Union recently held a meeting where the unfortunate situation of that branch of medicine was discussed. Although gonorrhœa had decreased by about one-third and syphilis by about two-thirds, the number of specialists for venereal diseases had increased by a quarter. It was stated that the recent law on the prevention of venereal diseases (mentioned in several of my former letters) had done harm to the profession in Berlin. Among other facts it was complained that if a specialist notifies under the law that a patient has interrupted treatment without being cured, the patient is summoned before the municipal health authority, and often sent back not to his medical attendant, but to one of the municipal dispensaries. This procedure is quite contrary to the agreement made between the city authorities and the union. It was moved that these abuses should at once be abolished, and that a fee for the notification of venereal diseases should be paid, as is legally provided for trades diseases.

Withdrawal of Medical Qualification.

It is very difficult in Germany to remove a medical qualification from a doctor proved unworthy to hold it. This can be done only if the qualification had been obtained by fraud, or when a medical man had been punished by a law court for a crime with the loss of civil rights, and then only as long as the punishment lasts. The government intend to alter this state of things, and have asked the opinion of the medical chambers on that subject. They propose that the qualification may be withdrawn if a medical man has proved not to possess the reliability necessary in his profession, but that the government shall be authorised to restore the qualification at its discretion. This provision has, however, not met with the approval of the chamber because it is too elastic. They are advising the Government to provide that the withdrawal of a qualification may be made legal if a medical man has been found guilty of severe criminal or moral offences, or if owing to a mental disease he is unable to practice. This, however, is to be done only if the supreme court of honour agrees, and the qualification may be re-granted only with the consent of that court. The matter is still in a preliminary stage and will not yet come before Parliament.

Special Motor Badge for Medical Men.

The German Motor Car Club (Adac) have resolved to introduce a special badge for the cars of their medical members. This badge will be a round plate with a red cross on blue ground and the arms of the Adac. The badge obliges the proprietor of the car to give first aid in accidents, to inform the next ambulance station, or to convey the injured to the nex hospital if necessary. He is further obliged to carr with him an adequate supply of medicaments fo first aid and material for dressings. The badge, whic is to be placed at the front of the car, will be given b the club to every member accepting the abov conditions.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub.-Lt. F. T. Doleman to be Surg. Lt.

Proby. Surg. Sub.-Lts. J. D. J. Freeman, J. A. Whit G. O. Barber, R. P. Davies, D. G. Evans, E. G. Thoma and D. A. Williams to be Surg. Sub.-Lts.

Surg.-Lt. E. E. D. Gray to be Surg. Lieut.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Capt. G. E. L. Simons to be Maj.

Temp. Lt. R. H. Dunlop relinquishes his commn.

F. H. A. L. Davidson to be temp. Lt.

REGULAR ARMY RESERVE OF OFFICERS.

Col. E. T. F. Birrell, late R.A.M.C., having attained th age limit of liability to recall, ceases to belong to the Re of Off.

TERRITORIAL ARMY.

Maj. W. A. Robertson to be Lt.-Col. and to comd. th 152nd (Highland) Fd. Amb.

H. G. Garland to be Lt.

ROYAL AIR FORCE.

The undermentioned are granted temporary commissio as Flight Lts. on re-employment: E. E. Isaac and G. S Ware (Hon. Squadron Leader).

Flying Officer A. L. St. A. McClosky is promoted to th rank of Flight Lt.

Capt. W. Wormington (Army Dental Corps) is granted temporary commission as a Flight Lt. (Dental) on attac ment to the R.A.F.

Flight Lt. W. R. Wotton (Capt. Army Dental Corp relinquishes his temporary commission on return to Arm duty.

DEATHS IN THE SERVICES.

Deputy Inspector-General Isaac Henry Anderson, R.N who died at Twyford, Winchester, on Feb. 2nd, aged 8 graduated M.D. at Queen's College, Belfast, in 1871, in whi year he entered the Royal Navy as surgeon. Appointed the *Salamis*, he served during the Egyptian War of 188 and for his services received the Egyptian medal and th Khedive's bronze star. He also served during the nav and military operations near Suakin in 1884, when he w awarded the Suakin clasp. After being promoted sta surgeon in 1883 and fleet surgeon in 1892 he had charge the naval hospital at Simons Town at the Cape of Go Hope, and received their lordships' approval for servic rendered at the hospital during the fever which occurr after the Benin Expedition. Later he served at Portsmout and retired in 1902. He was in receipt of a Greenwi Hospital pension for good services on the active list.

NAVY MEDICAL OFFICERS.

A Fleet Order calls the attention of medical and den officers to the regulations governing private professio practice. It is provided that if a plate is displayed it to show the officer's rank in the Navy, and must bear up it the words "Royal Navy." No hours of attendance s to be shown on the plate. No civilian appointment, su as on the staff of a civil hospital, is to be accepted with approval from the Admiralty.

COLONIAL MEDICAL SERVICES.

C. J. Wilson, Deputy Director of Medical Services, Ken has been promoted to be Principal Medical Officer, Federa Malay States.

The following appointments have been made:— Worger, Medical Officer, Fiji; C. E. Vaz, Medical Offic Public Hospital, Jamaica; G. D. Drury, Medical Offic Kenya; J. A. L. Innes, Medical Officer, West Afric Medical Staff, Nigeria, Southern Provinces; R. A. Newsc Medical Officer, Northern Rhodesia; R. H. Kippi Medical Officer, Somaliland; L. F. Day, Medical Offic Straits Settlements; A. McK. Fleming and I. C. Middlet Medical Officers, Tanganyika Territory; R. Stuart, Medi Officer of Health, West African Medical Staff (Colony allocated); R. Nicklin, Medical Officer, Zanzibar.

TREATMENT OF INFLUENZA.

THE PREVAILING EPIDEMIC IN LONDON.

To the Editor of THE LANCET.

SIR,—That the present epidemic of influenza will e excel in severity the visitations of recent years is eady only too obvious. Grave complications anifest themselves in the early stages of the disease, d may lead to death after an illness of three or four ys only. Powerless as we are to stem the tide now reading throughout the population, yet certain erapeutic measures, directed towards prevention or re of the complications, appear to be of definite lue, and of these I write.

Symptoms and Signs.—The outstanding symptoms a hundred cases observed during the last few eks were aching of the limbs, frontal headache, rd cough, sore-throat, and pain in the chest. The ter is limited to a small area of the chest wall, and, hough occasionally aggravated by inspiration, ually is unaffected by respiratory movements. nderness in the position of the pain is commonly nd together with limited movement of the chest the affected side. Auscultatory signs are wanting, d in the majority of cases the pain disappears in hours. Presumably a localised pleurisy is the cause the symptom. The temperature is found to be ised to about 102° F. in the afternoon, and falls to ° F. in the morning. The pulse-rate is raised oportionately. In cases which have subsequently veloped complications, however, the pyrexia has en of sustained nature at the outset, varying tween 103° and 104°. In such patients, on the ird or fourth day of the illness, the temperature and ılse have fallen during 24 hours, the change being sociated with a feeling of improvement on the part the patient. On the following day, however, both mperature and pulse have again risen to the former gh level, at the same time rapidly developing signs pneumonia have been observed. Leucocytosis is ten absent, and rarely exceeds 12,000. The fauces d palate are diffusely congested, but pus is seldom be found on the tonsils. In about 5 per cent. of ses there is tender enlargement of the glands lying ong the borders of the sterno-mastoid muscles.

Complications.—The cases presenting from the onset temperature of 104° F. with trivial daily fluctuations e those most prone to develop complications about e fourth day of the disease. These have been: ute otitis media, acute empyema of antrum, lobar eumonia, and septicæmia with no signs of localised flammation. The striking characteristic of all these ections is their extreme rapidity of development. slightly reddened tympanic membrane may change one bulged by pus in the course of a few hours. spite of early drainage acute mastoiditis follows dy too frequently. Similarly, one or more lobes of e lungs may become solid in the course of a few urs and a pleural cavity half fill with pus in a day. this year's epidemic the pneumonic signs are most always those of lobar distribution, in fact the gns and type of pyrexia resemble exactly those und in pneumococcal pneumonia, save that there is rely a crisis. Nevertheless, in all the complications entioned the preponderating organism is a hæmolytic ng streptococcus. It is this fact which suggests the ie of treatment to be followed.

Treatment.—In the first place, as soon as symptoms ve appeared, the patient must be put to bed, given brisk purge, and placed on a diet of fresh fruit—g., grape fruit and oranges and copious drinks of non squash, Contrexéville water, and not more an half a pint of milk daily. In uncomplicated cases, rtual starvation in this manner, good nursing, and fficient sleep, which must be procured, are all that necessary. If, however, the temperature is unusually high, the symptoms of exceptional severity and prostration marked, the case must be suspected as likely to develop grave signs. In all such intravenous administration of antistreptococcic serum should be practised. The dose to employ is 40 c.cm. daily for two or three days. It is quite remarkable to observe the sudden fall of temperature and subsidence of symptoms which often closely follows this measure. On the day following the first injection the temperature may be normal, but if no further serum be given, it often rises to 100° F. the next day, but this feature is of transient duration. Three of many cases thus treated had, in addition to the usual severe headache, high temperature and rapid pulse, respiratory rates of over 30 with pleuritic pain and grunting respiration, all of which developed in 36 hours. Within 12 hours of the injection of serum they were free from all symptoms save that of extreme lassitude.

Once pneumonia is definitely established serum appears to have but little effect. On the other hand, mercurochrome should be given a trial in these cases. I have seen recovery follow its use in apparently desperate cases of pneumonia and streptococcal septicæmia. The amelioration is shown after the first or second dose by the onset of lysis, fall of pulse-rate, and improvement in general condition. That recovery might have occurred in any case is, of course, the obvious and unanswerable comment. I can only reiterate that the use of the drug was apparently the means of averting death. Even if the evidence be slender from a scientific standpoint, yet when our patients are in peril such treatment, if not in itself a danger, should not be withheld. Of five streptococcal lobar pneumonias recently observed, four treated with mercurochrome recovered, the fifth treated on purely orthodox lines died. This may be pure coincidence. The preparation should be given intravenously as a 0·5 per cent. solution in doses of 10 to 15 c.cm. daily for three days. It is essential that the injection be made slowly. Larger doses are not to be recommended, and may produce severe griping. Empyemata should be aspirated repeatedly, and not subjected to open operation.

The *after-treatment* of influenza and its pulmonary complications is of the greatest importance. Palpitation and unstable pulse-rate are common sequelæ and referable to the effect of the toxin on the myocardium. These signs indicate further rest in bed, together with carefully graduated limb exercises supervised by a masseuse trained in the treatment of cardiac disease. If these exercises are skilfully prescribed the pulse shows progressive improvement in stability and rate, until the stage is reached when the patient can safely leave his bed. Kneading of the limb muscles is also of value in preparing the subject for convalescence, for it obviates much of the profound weakness which has characterised every influenzal epidemic of this century. Post-pneumonic cases should be given respiratory exercises, and these must be persisted in until equal movement of the two sides of the chest has been attained.

Finally, all but the mildest cases must be sent into the country for at least three weeks. During this time strychnine will be found of great value as a tonic, particularly in view of the low blood pressure which follows influenza and which will persist if convalescence is not properly supervised.

I am, Sir, yours faithfully,

A. H. DOUTHWAITE, M.D., M.R.C.P.,
Feb. 11th, 1929. Assistant Physician, Guy's Hospital.

NUCLEIN IN PNEUMONIA.

To the Editor of THE LANCET.

SIR,—Now that the scourge of influenza is again raging in Europe and America, and the death-rate from pneumonia is consequently increasing, may I, once more,[1] call attention to the method of

[1] See F. M. Gardner-Medwin: Brit. Med. Jour., 1924, ii., 497; and J. G. Willmore and F. M. Gardner-Medwin: THE LANCET, 1922, i., 116.

precipitating the crisis in pneumonia by means of intra-muscular injection of sodium nucleinate together with neutralisation of the subacidosis due to febrile toxæmia. A series of 40 consecutive cases was quoted of fulminating pneumonia so treated, in which the crisis was brought about in 48 hours or so with consequent defervescence and recovery, mostly occurring during the pandemic 1918. Since then my series has been uninterrupted so far as cases of lobar pneumonia, in previously healthy persons without crippling complications, is concerned. I do not claim that it is always successful in the ancient and infirm, or in advanced nephritics, or in the terminal pneumonias of long-standing disease, but I do claim that it is practically always successful in cases of straight pneumonia occurring as the result of the sudden lowering of resistance by influenza or sudden chill, and that these cases can be saved the debilitating strain of the long wait for the normal crisis which so often kills them.

Let me, then, formulate my credo: In influenza, leucopenia diminishes resistance. Saprophytic organisms become pathogenic. Sodium nucleinate releases leucocytes, latent in the bone-marrow, into the blood stream, increasing phagocytosis.

I believe that in nearly all cases of uncomplicated pneumonia, if sufficient bicarbonate of soda and glucose is given to render the urine alkaline or neutral, and 2 c.cm. of the solution of sodium nucleinate (put up by the Clin Laboratories of Paris) is injected intramuscularly into the thigh, in 48 hours or so the temperature will fall to normal, and convalescence will begin forthwith, and the patient will rapidly recover. I am not alone in my optimism, for Dr. L. E. Miller, of Lichtenburg, Transvaal, after using this method [2] on 117 natives, 87 of whom had lobar pneumonia, records a death-rate of only 8 per cent. He adds: "This treatment . . . is of definite assistance in terminating lobar pneumonia quickly and successfully."

I sincerely hope that practitioners who have used this treatment will give me the benefit of their opinion, and their results.

I am, Sir, yours faithfully,
F. M. GARDNER-MEDWIN.

St. Asaph, North Wales, Feb. 10th, 1929.

ASTHMA RESEARCH.

To the Editor of THE LANCET.

SIR,—My friend, Dr. Culpin, being, as he is, not merely a psychotherapist but a clinician of wide experience, has no need of aid in the present discussion. But I would like to suggest that some individuals who display the biochemical reactions upon which Mr. Coke and others lay such stress, in association with asthma, in the presence of cats, may well be thereby expressing a repressed or forgotten horror of cats due to some terrifying infantile experience. As a matter of fact, as some of us know, this is apparently the case often enough. And the most economical method of effecting a cure is to revive and explain the forgotten experience: not to carry through desensitisation in the absence of psychological investigation. On the other hand, those who have a lively horror of cats, present ever to their minds, and who do not hesitate to express what they feel, do not seem to suffer asthma and to display the biochemical reactions in question, even though, as sometimes happens, they have forgotten the early experiences in association with cats that have so impressed their organisations.

It seems relevant to point out that, at two recent medical meetings, papers were read on Vertigo (R.S.M., Section of Otology) and Exophthalmic Goitre (Manchester Medical Society). Mutatis mutandis, all that Dr. Culpin has said about asthma is applicable to these two maladies. Yet I have failed to find, in reports of these meetings, the faintest indication of awareness that psychotherapy does afford rapid and lasting relief to many persons suffering from vertigo or exophthalmic goitre without surgical treatment, or even in spite of it.

Surely some quickening of knowledge in respect of what I may call clinical psychotherapy is badly needed, and without delay. But, as I was recently asked, at a meeting of general practitioners, how is the general practitioner to learn? We have, first, to settle the problem of who is to teach the teachers—to say nothing about the researchers.

I am, Sir, yours faithfully,
Wimpole-street, W., Feb. 9th. F. G. CROOKSHANK.

To the Editor of THE LANCET.

SIR,—Mr. Coke evidently confounds psychotherapy with psychoanalysis. His emotional reaction to the latter is quite understandable, but there exists no necessity to have recourse to mysticism or pseudo-scientific theory. Pavlov's work, which is scientific work of the highest order, helps us to understand and explain most, if not all, cases of "psychogenic asthma," and there is no longer any doubt about its existence. I should like to refer Mr. Coke to the correspondence on this subject in your columns two years ago.[1]

I am, Sir, yous faithfully,
Shortlands, Kent, Feb. 9th, 1929. A. WOHLGEMUTH.

To the Editor of THE LANCET.

SIR,—Dr. Culpin and Dr. Ross have paraphrased sentences out of my letter at great length, in an attempt to produce a reductio-ad-absurdum argument to my contentions that nervous manifestations carry a stigma, especially when wrongly applied to asthmatics.

So far from being convinced by them, I hold that anything short of perfection in health, strength, and beauty carries with it a proportionate stigma, or mark of inferiority. If two women are sitting on a bench, the one with a fine healthy child, the other with a weakling, the mother with the latter child will "feel a bit green," to describe the complex in the vernacular. The small boy puts off going to the sick-house as long as is possible, because to do so is to drop behind a standard of perfection, probably in his case some beefy boy who is captain of the football team. If the young bride has the "misfortune" to be so "unlucky" as to marry a "poor fellow," whose "unhappy" lot it is is to "lapse" into a state of neurasthenia, who is there amongst her friends who will not "commiserate" with her in the family's "sad affliction"? The man of 6 boasts of his two rounds a day in the presence of the man who can only accomplish 18 holes. The old buffer, who can still stand up, chaffs his friend tucked up in a bath-chair.

But, to take the battle into the enemy's country, a patient was sent to me suffering from irritability, fits of temper, and some suggestion of developing grandiose ideas; these made it difficult for him to maintain a very substantial business position, or to live happily at home. Carrying out full protein tests I found that he gave a large reaction to potatoes. His temper and general equanimity returned to the normal on carefully avoiding that article of food. The work of W. R. Shannon in America demonstrates the connexion between the fractious, cantankerous child, with his bursts of temper, and sensitisation to foods. Lastly, I should be extremely interested to know whether people, who have this cat phobia, are indeed sensitive to cats, as demonstrable by the dermal reactions. Is it the sense of smell or sight that starts the alarm? Are they aware of the cat's presence, which to others is unsuspected?—conversely would they exhibit these fears if told a cat were present, when such was not really the case?

When one has seen such purely mechanical nervous action to take place as the paralysis of the accommodation of the eye following the eating of an apple or the development of a patch of herpes facialis following the ingestion of a piece of cheese, or a

[1] THE LANCET, 1927, i., 962, 1323, ii., 88.

ack of asthma from the unsuspected presence of a nea-pig in the room, it is difficult to say how many ser strings may not be played on by biochemical mechanistic means.

Where Dr. Ross gets his idea that I start by disieving my patients, or that I am lacking in charity, o not know. The palmists tell me that my thumb ns outwards to an astonishing degree.

I am, Sir, yours faithfully,

eb. 11th, 1928. FRANK COKE.

THE EGYPTIAN CONGRESS OF MEDICINE.

To the Editor of THE LANCET.

SIR,—It may appear ungracious to comment on very generous appreciation of our recent Centenary ngress in Cairo which appears in your issue of n. 12th (p. 101), but I would like to be allowed to rect a few inaccuracies which have unconsciously pt into your correspondent's account of the ceedings.

First, it is only right that a tribute should be paid the extraordinary keen and personal interest en in the Congress by H.M. King Fuad, whose mple served as a powerful stimulus to us all. His jesty was graciously pleased to receive at the hands the Chancellor, who is also the Minister of Educan, H.E. Ahmed Bey Lotfy El-Sayid, the first norary degree (Doctor of Laws) conferred by the yptian University. His name will also be ever ociated with the new hospital. The formula pted at the ceremony of the laying of the foundan-stone was :—

"This foundation-stone of the new buildings of Kasr-Ainy School of Medicine and the King Fuad I. Hospital, ich form the Faculty of Medicine in the Egyptian Unisity, was laid by His Majesty on Dec. 16th, 1928, in the venth year of his reign."

is perpetuating the name of Kasr-El-Ainy and orporating that of King Fuad at the same time. e new school is planned to provide for 600 students, l the hospital will eventually contain 1500 beds not 700 as stated—and allow of 3000 out-patient endances a day. In the year that is just past sr-El-Ainy gave relief to 18,000 in-patients and alled 510,000 out-patient attendances, an increase 12,000 over those for 1927.

Stress might also be laid on the extraordinary erest and enthusiasm caused by the conferring of Honorary Fellowship of the Royal College of rgeons on Aly Bey Ibrahim. This was a very turesque ceremony, distinguished by a brief but pressive address by Sir Berkeley Moynihan, the sident of the College. The memorising by the dents of some such striking phrase as "this is the hest honour the College has in its power to bestow" s clear evidence of the impression created by this narkable compliment extended to the Faculty of dicine of Cairo by the Council of the Royal College. e presentation of addresses and the reception of legates from all corners of the globe appealed very ongly to the staff and students of the Faculty, o were delighted to see so many leaders of the fession who hitherto had been only names to m.

With such a cosmopolitan gathering the selection recipients for honorary degrees was exceedingly ficult, and the following 20—not 13—were honoured the M.D. Degree at the final meeting of the ngress :—

Germany : Prof. Fülleborn, Hamburg ; Prof. Kleine, lin.

Belgium : Prof. Henri Frédéricq, Liège.

United States of America : Prof. Bailey Ashford, Porto o.

France : Prof. Lépine, Lyon ; Prof. Brumpt, Paris ; Prof. mas, Montpellier ; Prof. Vaquez, Paris.

Great Britain : Sir Berkeley Moynihan (M.S.), Sir Holburt ring (M.S.), Sir William Wheeler (M.S.), Sir Robert Philip, l Sir Cooper Perry (in absentia).

Greece : Prof. Aravantino, Athens.

Italy : Sir Aldo Castellani and Colonello Grixoni.

Japan : Prof. R. Kawamura.

Holland : Prof. Schuffner.

Prof. Euziere, Dean of the Faculty of Montpellier, Clot Bey's alma mater.

According to a precedent observed at all previous congresses held in Egypt, the names of the senior national delegates were submitted to His Majesty for honourable distinctions and were therefore not included in the list for honorary degrees, a circumstance which should be mentioned, to remove any misunderstanding on this score. The list of honours is being awaited with considerable interest.

Perhaps the most interesting incident in the course of the week was a meeting between H.E. Shaheen Pasha, Under Secretary of State for Public Health, and some of the principal British delegates at which a very frank and cordial conversation took place on public health questions in general, on the position of Egyptian students in England, and on the general medical relations between Egypt and England. All the delegates were unanimous in their appreciation of Shaheen Pasha's broad-minded views on all these matters and an excellent spirit of mutual satisfaction and conciliation prevailed.

Finally, a word of praise to Dr. M. Khalil, professor of parasitology, and secretary-general of the Congress, for his excellent work, would not be out of place. It was due to the cordial coöperation of the staff of the Faculty and the organisation committee that we were able to survive the strenuous labours entailed by a congress on such a comprehensive scale and to carry it through to a successful issue.—I am, Sir, yours faithfully,

FRANK C. MADDEN,
Dean of the Faculty of Medicine
Jan. 28th, 1929. Egyptian University.

*** We take the opportunity of adding that the Egyptian Government has issued two postage stamps to mark the importance of the occasion. The first (5 milliemes) depicts Imhotep, the Egyptian deity of

medicine, seated on his throne, grasping the sceptre of power in his right hand, and the "ankh" or symbol of life in his left. The second (10 milliemes) is a portrait of the Viceroy Mohamed Aly Pasha, to whom the foundation of the medical school of Cairo 100 year ago was due. Dr. Jamieson B. Hurry, who sent us the stamps, remarks that this is probably the first time in the history of medicine that one of its tutelary deities has appeared on a stamp.—ED. L.

INSULIN IN OILY SUSPENSION.

To the Editor of THE LANCET.

SIR,—More than a year ago I came to the conclusion that some cases of diabetes mellitus with the usual typical thirst, polyuria, and hyperglycæmia made a complete recovery provided they were treated with a fixed diet which supplied sufficient energy and tissue-repairing protein along with insulin

in doses which kept the concentration of the sugar in the blood below 0·15 per cent. throughout the 24 hours. In order to obtain this control of sugar in the blood some cases might require four or more injections of insulin during the 24 hours; this made the treatment very difficult. It occurred to me that it might be possible to prolong the action of an injection of insulin by delaying its absorption and thereby obtain the desired effect. I considered several possible methods, and in August of last year I asked a manufacturer of insulin to supply me with an oily suspension.

Since November last I have used this in private and at the London Hospital, and find that I can give 90 units as a single dose, which will control the sugar in the blood just as well as three aqueous doses of 30 units each at intervals of six hours. I have used an oil that is acceptable to some patients, whilst others complain of pain lasting some time after the injection. The ideal oil will not give rise to pain, but it must be capable of keeping in suspension at least 60 units of insulin per cubic centimetre if it is to be used in very severe cases. The optimum concentration of the injection will have to be determined for each case.

I shall feel indebted to any one who gives me a list of oils the hypodermic injection of which does not lead to discomfort.

I am, Sir, yours faithfully,

Portland-place, W., Feb. 11th, 1929. O. LEYTON.

LOCAL ANÆSTHESIA IN UPPER ABDOMINAL SURGERY.

To the Editor of THE LANCET.

SIR,—A large experience of novocaine in spinal analgesia, resulting from the routine use of it in the practice of two general hospitals, prompts me to add a few observations to the very instructive paper by Prof. Pannett in your last issue.

First, I suggest that dosage should always be indicated by the number of centigrammes of solid novocaine injected, for the actual percentage solution of the drug in the cerebro-spinal fluid is an unknown quantity, and the presence of ampoules of different percentage strength about an operating theatre is a trap for the unwary who think in cubic centimetres. The 10 per cent. solution in normal saline is certainly the most convenient to use, because each tenth of a cubic centimetre contains one centigramme. I believe that the extent of analgesia obtainable is directly proportional to the amount of drug injected, that its extension is mainly by diffusion, that gravity plays a small but unimportant part and is of little practical help. The higher the injection is made the greater the chance of high diffusion. I have so frequently injected between D. 12 and L. 1 without regret, that I cannot help thinking that the spinal cord is in little danger, provided that the needle is not plunged haphazard into the theca, but only so far as to obtain fluid. Between L. 1 and L. 2 I regard as safe.

The extent of the result must be estimated, and if deficient a second injection may be made to enhance it. On no account may the patient be questioned as to his sensation, for if this is done his confidence is lost. A small dose in the lower intervals will result in tingling in the legs, absence of sphincter reflex, loss of corrugation at the anal margin, and the operation for piles may be commenced. With increasing doses at higher levels inability to raise the legs proves that the lumbar segments are out of action, and paralysis of the lower rectus gives a characteristic appearance which is unmistakable (D. 9–12). If the upper segments of the muscle are unaffected, the umbilicus is drawn up when the patient coughs. At this level analgesia of the abdominal wall below the umbilicus may be relied upon, but splanchnic sensation may be felt when the appendix is delivered, often as windy or colicky pain in the epigastrium. Analgesia involving the nipples implies, as Prof. Pannett says, that the splanchnic communications are cut. Slight tingling in the upper limbs foretells that the surgeon is likely to make an easy exit from the abdomen if he does not much exceed one hour.

Nausea and vomiting are unfortunate accompaniments, but generally indicate high level results. The onset is from about 20 minutes after injection, and its duration corresponds to the period of lowest blood pressure. From its termination the condition of the patient may be expected to improve steadily towards the end of the operation, when the pulse may be satisfactory and there may be no post-operative shock. It is quite common for the pulse to become infrequent and as low as 40 per minute; it may also be impossible to feel it in the temporal artery. The dose may be up to 15 centigrammes, with from 10–12 as an average, but more than this has often been given in some of my cases when more than one injection has been given. The toxic effect of any quantity of novocaine likely to be used in this method is negligible, but this cannot be said of stovaine.

Progress in this method is, I believe, likely to be made by greater confidence in administration, more certain estimation of results, and a realisation that a second injection may be made to improve those which are imperfect. That this is the easiest and most certain way of obtaining splanchnic block, I have no doubt. That it will ever by itself become the method of choice for serious high operations I do not believe, unless the fall of blood pressure can with certainty be countered; for it may be a trial of fortitude for the most phlegmatic patient, and the more nervous he is the less welcome will it be. That it can be so used, if necessary, is certain. Its ordinary use for these cases is in combination with general anæsthesia, and tracheal insufflation offers the widest margin of safety. For minor abdominal work and low operations it has long been a commonplace success though pneumonia sometimes follows its use. Doubt cast upon the efficacy of novocaine can only be explained by imperfect knowledge of dosage, which is at least double that of stovaine.

I am, Sir, yours faithfully,

W. HOWARD JONES, M.B., B.S. Lond.,
Surgeon-Anæsthetist to Charing Cross Hospital.

London, W., Feb. 12th, 1929.

THE TREATMENT OF HÆMORRHOIDS BY INJECTION.

To the Editor of THE LANCET.

SIR,—Dr. Whitcombe's last letter calls for a brief reply from me, if only to point out the peculiar method he has of giving references. He quotes a paragraph which he alleged that he took from "the text of the official report, which followed the proctological meeting at the Royal Society of Medicine on July 9th, 1924." Naturally, I assumed that he referred to the Proceedings of the Royal Society of Medicine. But when I turned to that volume I found not a word of Dr. Whitcombe's quotation, but a summary without comment of the various papers and speeches, which is almost identical with that published in THE LANCET (1924, ii., 117)—the reference given by Dr. Whitcombe in the letter in which he first attacked the treatment of hæmorrhoids by injection.

Having found that both his references were misleading, I was compelled to ask him personally whence he had quoted, and ascertained from him that his quotation was not really from "the official report" nor from THE LANCET, but from a report of the same meeting in the *British Medical Journal* of July 19th 1924. In this number of your contemporary a verbatim report is given of the opening paper of the late Mr Græme Anderson, who up to the time of his lamented death was an advocate of the treatment by injection. On another page of the same number of the *Journal* is a very brief summary of the remaining speeches made at the meeting. This is written by somebody who obviously had a strong bias against the treatment, because, apart from referring to Mr

nderson's paper on another page, it quotes only peeches made by two American surgeons who were iolently opposed to the treatment, and does not efer at all to those of the numerous British and merican surgeons who spoke in favour of injection. n the middle of this short summary the words quoted y Dr. Whitcombe appear. But anybody who takes ne trouble to read the summary of all the papers and peeches, either in the "official report" or in your own eport of the meeting, will agree that the "general pinion" was certainly not that arrived at by the eporter in your contemporary and by Dr. Whitcombe.

Dr. Whitcombe accuses me of inconsistency, and quires why I have changed my methods of injection. y reasons were fully set out in the paper of mine hich you published.[1] and in the recently published print of my book on Hæmorrhoids. Briefly, they ere in order to eliminate the few and rare compli- tions which occurred with the older methods— mplications which were not as numerous nor as rious as those mentioned by Dr. Whitcombe as casionally occurring after treatment by galvano- utery. I should still hesitate long before I injected oily solution into the veins of the pile-mass. The *bmucous* injection of an oily solution is quite another atter.

No doubt Dr. Whitcombe's results from treatment galvano-cautery are satisfactory on the whole, it I am not convinced that his method is either as tisfactory or as safe as the treatment by sub- ucous injection, and it is certainly more lengthy d troublesome both for the patient and the surgeon.

I am, Sir, yours faithfully,

ARTHUR S. MORLEY.

Upper Wimpole-street, W., Feb. 9th, 1929.

TONSILLECTOMY IN CHRONIC ARTHRITIS.

To the Editor of THE LANCET.

SIR,—Mr. Pavey-Smith's paper and the leading ticle in your issue of Jan. 26th bear out the opinion ave often expressed that tonsillar infection seldom ars any relation to chronic articular rheumatism.

200 cases only out of a total of 7000 cases rheumatic disease were the tonsils considered fficiently infected to warrant enucleation. As 44 of ese 200 were of the acute rheumatic type, these ould be excluded as it is, I think, agreed that the iology of rheumatic fever and of so-called chronic eumatism of joints is not the same. If we also take t fibrositis, neuritis, and sciatica we are left with ne 120 cases, or less than 2 per cent. of the whole mber. Of these, 15 reported themselves as cured d 65 as improved, which works out at just about er cent.

The bacteriological findings are of considerable erest. These also confirm my own experience that hæmolytic streptococci never have any direct sal connexion with arthritis. When present in tonsil and causing actual tonsillitis, no doubt they er the general resistance of the system, but non- molytic streptococci are, on Mr. Pavey-Smith's wing, far the most important in chronic arthritis. ne compares these statistics with those of Howarth l Gloyne, who found that hæmolytic streptococci urred in the ratio of 16 to 22 of non-hæmolytic, re is but little difference; not more than would be ounted for by the fact that the former are from ldren only in whom sore-throats are more common. m the adult tonsil, unless acute tonsillitis is ually in being, it is unusual to cultivate a hæmolytic ptococcus. That a white staphylococcus was nd in pure culture in two tonsils in cases of umatoid arthritis (infective arthritis D. where no is of infection was discovered) is in accordance h my hypothesis that a white staphylococcus ction (*M. deformans*) is the primary cause of umatoid arthritis.

To sum up, tonsillar infection is of outstanding portance in cases of acute and subacute rheumatism. It is of much less importance in all other forms of infective arthritis, and in cases of osteo-arthritis the tonsils as a focus of infection may be completely disregarded. Only one case occurs in Mr. Pavey-Smith's series.

I am, Sir, yours faithfully,

London, W., Jan. 30th, 1929. H. WARREN CROWE.

RADIUM TREATMENT OF CANCER IN FRANCE AND BELGIUM.

To the Editor of THE LANCET.

SIR,—In their article on this subject (THE LANCET, Feb. 9th) Mr. Armour and Mr. Souttar pay very gracefully a well-merited tribute to the great courtesy and kindness extended by the staffs of French and Belgian radium clinics to them as to many other visitors for years past. They do not mention, however, one particular in which the workers of Brussels and Paris have seemed to outshine some others. It is in their willingness not only to give, and give generously, of their experience, but in their equal readiness to learn and to avail themselves of suggestions put forward by their visitors. Notwithstanding the handsome words in the closing paragraph about workers at home, the article hardly seems to us to disclose familiarity with the stage radium work in this country has reached. For example, after reading the account of Columbia paste, an English surgeon would perhaps be surprised to hear that this wax, in convenient sheets of standardised thickness (15 mm.) and standardised melting point, can be purchased over the counter at a well-known chemist's in Oxford-street, or that the salesman will naturally say, "Do you want the lead, Sir?" referring to sheets of standard thickness beautifully rubber-covered.

There is no reason, of course, unless a visit were paid to home clinics, why the authors of the article should know this, or that the Brussels "shavings" method—which is difficult—is being substituted in London by the use of plastic wood.

We are, Sir, yours faithfully,

E. ROCK CARLING,
London, Feb. 10th, 1929. STANFORD CADE.

MARVELLOUS MONTPELLIER MIDWIFERY.

To the Editor of THE LANCET.

SIR,—About eight months ago I published in your columns[1] a note under the above heading, in the hope that a little ridicule, culled from the old Montpellier doctor, Rabelais, would prevent your readers from attempting "the delivery of women by appointment at a fixed hour" introduced by the modern Montpellier doctor, Prof. Delmas. The latter's method consists in rapid manual dilatation of the cervix under the influence of spinal anæsthesia, followed by version or forceps, and is a revival of "accouchement forcé," with the additional risk of spinal anæsthesia.

Three French obstetricians appear to have taken Prof. Delmas *au sérieux* and have put his method to the test—not, indeed, to deliver ordinary cases "painlessly, by appointment, at a fixed hour," but for certain definite indications calling for artificial delivery. Their cases, 14 in number, should be read[2] by those who contemplate trying the method of Delmas. Of Mr. Laurier's eight cases, one died of post-partum hæmorrhage, seven had lacerations of the cervix, and three had slight tears of the perineum. Three children were dead before the operation. Mr. Laurier calls attention to the facility with which the cervix can be dilated in certain cases—in some it was incomplete—but "does not think the method a safe one to be placed in all hands and without formal indications." The results, above mentioned, seem to call for a stronger condemnation.

[1] THE LANCET, 1928, i., 1250.

[2] Bulletin de la Société d'Obstétrique et de Gynécologie de Paris, December, 1928.

Of Mr. Metzger's five cases, in one it was impossible to dilate the cervix, in two others there was difficulty in performing version or embryotomy, the difficulties being due, in the author's opinion, to the hypertonicity of the body of the uterus caused by the spinal anæsthesia. One of the cases died of post-partum hæmorrhage on the fourth day of the puerperium, and in two other cases post-partum hæmorrhage occurred. The author, "having never seen such a rapid death from bleeding on the fourth day," thinks that the bleeding may have been due to sudden relaxation of the uterine hypertonicity. He concludes: "For my part, after what I have seen, I am little disposed to make any more trials, and I cannot too strongly recommend prudence."

Mr. Cathala's single case was treated under spinal anæsthesia, owing to the existence of tuberculous laryngitis. The dilatation of the cervix was difficult and incomplete. The child was delivered by forceps. Slight tears occurred in the cervix and fourchette. The puerperium was febrile, and the patient died in an attack of cyanosis one month and two days after delivery. Mr. Cathala gives an excellent criticism of the use of spinal anæsthesia for the purpose of facilitating the dilatation of the cervix in obstetrical cases, and of Delmas's method he says, that it should be rejected if it has no other object than to obtain "a painless delivery at a fixed hour."

I am, Sir, yours faithfully,

HERBERT R. SPENCER.

Public Health Services.

INFLUENZA.

CLINICAL reports indicate that influenza is rather more widespread throughout the country than a week ago, although in general the type of disease is mild. Prevalence in Manchester, Liverpool, and the Lancashire towns continues, and there is a spread eastward to Leeds and Bradford. The extent to which the reported deaths in London and the great towns have risen during the week is shown in the following summary. In London the epidemic is now more evenly distributed and is still described as mild in type. In the Scottish 16 towns the general death-rate fell from 37·9 to 28·2 for the week ended Feb. 9th. The towns showing a rise are Edinburgh (33·7), Dundee (37·7), Kirkcaldy (23·9), and Ayr (26·0). The general death-rate in Glasgow was 27·6. Deaths from respiratory diseases in the 16 towns numbered 449, as against 675 in the previous week, and those from influenza 220 as against 323. Pneumonia notifications fell from 1268 to 919.

Reports published by the Health Section of the League of Nations indicate that the epidemic is subsiding generally. The rate of progress of influenza across Europe has not been as rapid as it was in 1921–22 and 1926–27, and in certain limited areas on either side of the Irish Sea and North Channel the disease has prevailed in a more severe form than in either of these two outbreaks. It has been widespread in Southern Norway, in Copenhagen, and adjacent regions of Denmark, as well as on the shores of the Finnish Gulf, including both the Finnish and Esthonian coasts, but the prevailing type has been mild hitherto. In Germany only Brandenburg, Saxony, Lower Silesia, and Bremen have been seriously affected up to the present, and death-rates have in no case been more than half as high as those recorded in Western Scotland and Northern Ireland. An outbreak of average severity occurred in Madrid in January. Influenza has now made its appearance in parts of the Netherlands and Northern France, but at the beginning of February it was still rare elsewhere in Europe. The influenza epidemic which has traversed North America from west to east is now definitely on the decline.

INFECTIOUS DISEASE IN ENGLAND AN WALES DURING THE WEEK ENDED FEB. 2ND, 1929.

Notifications.—The following cases of infectiou disease were notified during the week:—Small-po 230; scarlet fever, 2490; diphtheria, 1444; enteri fever, 34; pneumonia, 3511 (last week 2422); pue peral fever, 40; puerperal pyrexia, 129; cerebr spinal fever, 5; acute poliomyelitis, 3; acute poli encephalitis, 2; encephalitis lethargica, 14; dyse tery, 10; ophthalmia neonatorum, 83. No case cholera, plague, or typhus fever was notified durin the week.

Cases of pneumonia were reported from every count the largest numbers being London, 513; Chester, 15 Durham, 149; Essex, 123; Lancaster, 965; Warwick, 12 Yorks West Riding, 292.

The number of cases in the Infectious Hospitals of t Metropolitan Asylums Board on Feb. 5th–6th was as follow Small-pox (44 under treatment, 4 under observation scarlet fever, 1903; diphtheria, 2071; measles 56; whoo ing-cough, 791; puerperal fever, 19 (plus 7 babies); enceph litis lethargica, 78; poliomyelitis, 5; "other diseases," 6 At St. Margeret's Hospital there were 13 babies (pl 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, includi London, there was no death from small-pox, 2 (0) fro enteric fever, 53 (2) from measles, 9 (2) from scarl fever, 149 (49) from whooping-cough, 46 (13) fro diphtheria, 65 (11) from diarrhœa and enteritis und two years, and 652 (198) from influenza. The figur in parentheses are those for London itself.

The number of deaths from influenza during the previo eight weeks was 60, 61, 69, 83, 99, 122, 179, and 321 respe tively, the rate of rise being much steeper in the last thr weeks. The figures for London during the previous eig weeks have been as follows: 10, 9, 9, 15, 18, 34, 39 and 7 The deaths from influenza in the week under review st occurred largely in the Midland and Northern countie Liverpool, 75; Manchester, 43; St. Helens, 29; Port mouth, 25; Southampton, 19; Birkenhead, 17; Bootle, 1 Warrington, 13; Wallasey, 11. No other great town h as many as ten. Glasgow reported 184 (a substanti diminution from 236 in the previous week), Belfast 105, a Edinburgh 41 during the same week. The two deat from enteric fever outside London occurred at Preston a Sunderland. Liverpool reported 14 deaths from measl Cardiff 8, and Newcastle-on-Tyne 5. In Manchest 13 deaths from whooping-cough were reported, 11 fro Liverpool, 7 from Warrington. Birmingham stood highe for diphtheria with 4 deaths. Liverpool had 11 deat from diarrhœa, Birmingham 7, and Salford 6.

The number of stillbirths registered during the we was 275 (corresponding to a rate of 42 per 10 births), including 43 in London.

FRENCH HOSPITAL AT TANGIER.—Owing to t inadequacy of hospital accommodation at Tangier it h been decided to add a new wing and other accessories to t French hospital, thus increasing the accommodation native patients.

CONFERENCE ON MATERNITY AND CHILD WELFA The fifth English-Speaking Conference on Maternity a Child Welfare, organised by the National Association for Prevention of Infant Mortality, in coöperation with Maternity and Child Welfare Group of the Society Medical Officers of Health, and numerous other organisatio together with representatives from the Dominions, will held at Friends House, Euston-road, London, N.W., fr Tuesday, July 2nd, to Thursday, the 4th, with visits institutions on Friday, the 5th. The main subjects discussion will be the care of the child between 1 and 5 ye of age; maternal mortality and morbidity; the holdin special venereal diseases clinics for women and children connexion with maternity and child welfare departmen and the suffering entailed on mothers and young children prolonged waiting in out-patients' departments of hospit Lectures and film displays will be given during the eveni and arrangements will be made for visits to a wide rang child welfare institutions in London. Sanction has b given by the appropriate authorities for the payment expenses of delegates from local authorities, and rail companies in Great Britain have agreed to issue ticket reduced rates. Further information is obtainable f Miss Halford at 117, Piccadilly, London, W. 1.

Obituary.

THOMAS DUNCAN GREENLEES, M.D., F.R.S. EDIN.

WE regret to announce the death of Dr. T. D. Greenlees, which took place on Jan. 22nd at St. Leonard's-on-Sea, where he had lived in retirement for the last few years. The son of Dr. Thomas Greenlees, he was born in 1859 at Ballantrae, Ayrshire. His medical studies were pursued for a year in Glasgow University, and thereafter in Edinburgh University, where he graduated as M.B. in 1882 and as M.D. in 1901. After a short experience of general practice, he joined the staff of Garlands Asylum, Carlisle, in 1884. Three years later he became assistant medical officer to the City of London Asylum at Dartford, and in 1890 he was appointed medical superintendent of the Grahamstown Asylum, South Africa, a post which he held for over 17 years. He returned to this country in 1908 to take charge of a private asylum at Tulse Hill, resigning in 1913. He held a commission as surgeon-captain in the Boer War, and from August, 1914, to July, 1918, he was a major in the Royal Army Medical Corps, and held several important home appointments.

High intellectual attainments, alertness, great force of character, and untiring energy combined to make Dr. Greenlees a very capable asylum administrator. He did original research work as an assistant medical officer, and in 1885 he gained the blue ribbon of the Medico-Psychological Association for his prize essay on Diseases of the Circulatory System in the insane. He also made several important contributions to psychiatry in medical journals both in this country and in South Africa and America. Handicapped though he was by his health, which was never very robust, his enthusiasm and energy carried him further than most, while his kindly and sympathetic nature made him many life-long friends. At one time president of the Caledonian Medical Society, he also represented South Africa for many years on the Council of the British Medical Association.

Dr. Greenlees is survived by his widow, two daughters, and a son.

HENRY H. L. PATCH, M.R.C.S. who died on Feb. 7th, aged 58, was in practice in Liverpool as an anæsthetist, and was held in high esteem by his colleagues in the district. He received his medical education at St. Thomas's Hospital, and after qualifying was appointed house surgeon to the Devon and Exeter Infirmary, where his grandfather and great-grandfather had been surgeons. After 18 months there he entered general practice at Chudley, Hertford, and London. Eight years ago he went to Liverpool, where he devoted his whole time to the administration of anæsthetics, in the art of which he had unusual ability. He was anæsthetist to the Royal Infirmary, the Northern Hospital, the Liverpool Medical Research Organisation, and the Ministry of Pensions. "His quiet confidence and wonderful disposition," writes a colleague, "were of great advantage to those with whom he worked. A most unselfish character and kindness of heart won for him many friends, and his death will be an irreparable loss to them all. The last three years of his life were harassed by illness, but he carried out his duties with magnificent fortitude, both in the hospitals to which he was attached and in private practice." Dr. Patch leaves a widow with a son, and two grandchildren.

Dr. HERBERT ARTHUR SMITH, who died at Ealing on Jan. 29th, in his seventy-seventh year, was the son of Dr. Thomas Smith, of Wheatley, Oxon., where he was born in 1852. He was educated at Durham and Edinburgh Universities, and studied medicine at St. Mary's and Middlesex hospitals, qualifying L.S.A., and L.R.C.P. Edin. in 1878, and M.R.C.S. Eng. in the following year. After holding house appointments at several London hospitals and acting as medical officer to cable-laying ships, he took the M.D. Durh. before settling down in general practice at Ealing. While acting as surgeon to the cottage hospital there, his interest in mental and nerve diseases grew, and he finally devoted himself largely to them alone; a study of the biological and clinical aspects of pain appeared from his pen in a hospital journal. Besides, he was a ready writer on popular scientific subjects, his last book being a collection of verses aimed at bringing the doctrines of revelation into line with modern scientific thought. To the last he remained a student, keeping closely in touch with the modern theory and practice of medicine.

WE have to record the death, on Jan. 31st, of KENNETH BAMFORD WILLIAMSON, M.B. Edin., at the age of 33, after two days' illness. The son of Mr. Bamford Williamson, of North Shields, he was educated at Mill Hill. Throughout the late war he served with the Royal Garrison Artillery, winning the Military Cross, and retiring with the rank of Major. At Edinburgh University, where he took up the study of medicine, he graduated in 1921 with second-class honours, later holding resident appointments at the Edinburgh Royal Infirmary and the Royal Maternity and Simpson Memorial Hospitals. After further experience in London, as house physician to the Paddington Green Children's Hospital, he went to Penrith as assistant to Dr. D. C. Edington, whom he subsequently joined in partnership. His work as practitioner in Penrith, where he was also medical officer to the cottage hospital, was greatly valued in the town, and at his funeral there was much evidence of the affection in which he was held. Dr. Williamson's widow, who is left with a son two months old, is a daughter of the late J. Simpson Harker, of Penrith.

JOHN ADOLPHUS SHARP, M.R.C.S., who died on Jan. 26th in his eighty-second year, spent almost the whole of his long professional career in Derby, where he was still in practice at the time of his death. He first went to the town as house surgeon to the old Derbyshire General Infirmary, soon after qualifying from Guy's Hospital in 1868, and he later became surgeon to this institution. In 1896 he retired from practice, and his place was taken by Dr. C. H. Taylor; but ten years later, on Dr. Taylor's death, he resumed his active work, and continued for the rest of his life to take a considerable part in local affairs. Dr. Sharp's widow is a daughter of the late Edward Dumas, of Derby, and he leaves a daughter and a son, Dr. J. E. Sharp, of Chelsea.

WE have received from Colonel A. W. Sheen the following tribute to the late Dr. JOHN OWEN, of Liverpool, whose death was announced last week in our columns:—

"I am minded to write a tribute of warm affection and regard, shared I know by all his war comrades, to the life and memory of John Owen. When I commanded the Welsh Hospital in India, of 3000 beds, 'Major John,' as we all knew him, was in charge of the Medical Division. His good work, his kindness, and his personal charm endeared him to all. And there were in his character special traits of modesty, humour, and fearlessness. The last was shown by his zeal for big game-hunting, and by his sorrow that his lot had not been cast in a more active theatre of war. But duty was paramount with him; our change of destination from France to India he accepted with willing cheerfulness. Although, later, the charge of a hospital ship brought him in contact with Mesopotamia, yet the field of battle did not come his way.

His loss will be felt by all the many with and for whom he lived and worked in Liverpool, and not least by his comrades in the war."

As a memorial to Dr. Owen it has been decided to open a fund to endow one or more beds in the children's ward of the Carnarvonshire and Anglesey Infirmary at Bangor. Subscriptions may be sent to Mr. Pugh, the manager of Lloyd's Bank in that city.

THE LATE DR. J. E. EDDISON.—Dr. Wardrop Griffith, of Leeds, to whom we were indebted for some of the particulars in the obituary notice last week of Dr. J. E. Eddison, writes to say that the date of Dr. Eddison's appointment to the Infirmary was earlier than stated—namely, in 1871. Dr. Griffith did not succeed Dr. Eddison directly; it was Dr. Eddison's resignation that led to his being elected as the junior member of the honorary staff.

Lieut.-Colonel C. T. Samman, Master of the Society of Apothecaries of London, informs us that Dr. DE HAVILLAND HALL, an obituary notice of whom appeared in our columns last week, was a prominent member of the Society's Court of Assistants, where his valued opinions and advice, so courteously expressed, were always listened to with great respect.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent congregations the following degrees have been conferred:—

M.B. and M.Chir.—Francis Howitt Gillett.
B.Chir.—Donald Bagster Wilson.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Final Examination held from Jan. 8th to 30th the following candidates were approved in the undermentioned subjects, but are not eligible for the diplomas of the Board:—

Medicine.—Annie F. Allport, Royal Free; J. C. Arthur, Durham; Audrey Z. Baker, Univ. Coll.; S. G. Bedford, Leeds; R. M. Bolam, Cambridge; J. J. Boulle, London; W. V. Bowman, St. Thomas's; Mabel Brewster, Royal Free; T. D. T. Brocklehurst, Guy's; P. P. Chandu Nambiar, Birmingham; A. Clark, London; F. S. Cooksey, King's Coll.; D. M. Craig, Middlesex; H. R. J. Donald, Manchester; F. A. T. Edwards, St. Bart.'s; Lilian P. Edwards, Royal Free; L. M. Edwards, Cardiff and St. Bart.'s; R. G. P. Evans and R. S. M. Fisher, Middlesex; S. K. Foster, Leeds; I. Friedman, R. L. Frost, and D. K. Gaitskell, Guy's; Kathleen E. Gambrell and Alice E. N. Gilby, Royal Free; A. Gilpin, King's Coll.; C. G. Gordon-Wilson, London; Amy L. F. Hankins, Royal Free; K. W. D. Hartley, St. Bart.'s; W. Heard, Middlesex; A. H. Hennessy, Adelaide and London; I. P. G. Howells, St. Mary's; D. Hugo, Guy's; H. P. Hutchinson, St. Bart.'s; D. W. S. Kaye, King's Coll.; M. Kokia, Westminster; J. C. Lee, London; S. D. McClean and E. M. MacLachlan, Guy's; R. G. Mayer, Bristol; I. B. Morris and R. J. L. O'Donoghue, Guy's; Gwendoline Orlebar, Charing Cross; B. J. W. Pilsworth, Royal Free; H. Raj, Birmingham; B. V. P. Reddy, London; J. A. Robson, St. Bart.'s; R. M. Sargent, Univ. Coll.; B. Singer, London; D. B. Smallshaw, Guy's; J. O. Smith, Melbourne; W. H. B. Spoor, St. Thomas's and Bristol; J. B. Sugden, Leeds; R. S. Thomas, A. E. Treweek, and J. J. van Niekerk, Guy's; W. J. Walter, St. Bart.'s; S. N. Wasti, Punjab and London; G. J. S. West, Bristol; S. J. Wheeler, Guy's; Camille Wiseham, Calcutta; and Joyce R. Woods, Royal Free.

Surgery.—E. G. Abdel-Malek, Birmingham; D. A'Brook, Univ. Coll.; S. Alstead, Liverpool; H. F. Apthorpe-Webb, St. Bart.'s; J. C. Arthur, Durham; A. R. Banham, Cambridge and Middlesex; I. T. Barling, St. Thomas's; H. J. W. Bergh, St. George's; D. Bielenky, Westminster; M. Bloom, Cardiff; H. O. Clarke, Dublin; J. R. Colville, St. Bart.'s; P. A. Cooper, Univ. Coll.; W. J. Cotton and D. W. C. Cox, Guy's; D. M. Craig, Middlesex; J. R. Crumbie, St. Bart.'s; F. A. D'Abreu, Birmingham; P. Dalzell, St. Bart.'s; E. C. Dayus, St. Mary's; C. D. D. de Labilliere, St. Bart.'s; Jessie E. Dodds, Sheffield; C. de M. Dorey, St. Mary's; W. J. L. Downing, Middlesex; G. Duckworth, St. George's; D. H. A. Edmondson, Liverpool; B. M. Fonseka, Middlesex; E. S. Fossey, Otago; N. D. Gerrish, Bristol; G. H. A. Graetz, St. Bart.'s; E. Grundy, Leeds; P. N. Hanson, A. G. J. Harris and R. L. H. Harris, St. Bart.'s; H. L. Hoffman, Cambridge and St. Thomas's; J. Hopton, St. Bart.'s; D. Hugo, Guy's; E. F. Hunt, St. George's; April D. James, Bristol; D. S. Jones, St. Bart.'s; R. A. Jones, Univ. Coll.; C. Jotikasthira, St. Thomas's; H. V. Knight and N. Kramer, St. Bart.'s; R. A. Leader, Guy's; J. M. Leggate, Liverpool; F. T. F. Lutter, St. George's; H. G. McGregor, Guy's; F. M. Mallinson, Univ. Coll.; R. B. Mayfield, St. Thomas's; T. J. Millin, Dublin; A. J. Moffett, Birmingham; G. B. Mohile, Guy's; Q. St. L. Myles, St. Thomas's; L. P. Naz, Univ. Coll.; E. J. Neill, Cambridge and St. Bart.'s; S. W. K. Norris and J. R. Owen, Birmingham; W. Pearce, Leeds; F. R. A. Philpott, Oxford and Charing Cross; E. S. Pope and R. K. Price, St. Bart.'s; C. F. H. Quick, St. Mary's; W. Radcliffe, St. Bart.'s; B. Rait-Smith and P. J. Richards, Cambridge and St. Bart.'s; Ivy H. V. Rowlands, Liverpool; C. StJohnston, Birmingham; R. P. W. Shackleton, St. George's; A. R. Smith and J. H. Smith, St. Thomas's; D. Stephens, St. Bart.'s; Mary S. Stuart, St. Mary's; J. B. Sugden, Leeds; L. Sumitra, St. Mary's; D. J. Turnbull and C. E. H. Turner, London; G. S. Walker, Univ. Coll.; J. V. Walker, Birmingham; R. Warnecke, London; J. H. Watkin and T. H. N. Whitehurst, St. Bart.'s; R. L. Whittaker and A. S. Wigfield, Univ. Coll.; E. R. Williams, St. Mary's; J. O. Williams, St. Bart.'s; M. G. Woolff, St. Thomas's; Mary Worthington, Royal Free; B. Wright, Cambridge and St. Bart.'s; P. Yarmarko, Middlesex; and R. H. Young, St. Thomas's.

Midwifery.—H. S. Atkinson, London; E. F. D. Baker, St. Bart.'s; G. Balasuriya, Guy's; A. R. Banham, Cambridge and Middlesex; J. R. J. Beddard, St. Bart.'s; W. V. Bowman, Cambridge and St. Thomas's; A. M. Boyd, St. Bart.'s; Julia A. Boyd, Royal Free; C. E. Brierley, Bristol; H. P. Brody, Sheffield; W. D. Brown, London; A. Buch, St. Mary's; G. H. Buck, Westminster; A. C. Byles, St. Mary's; S. Chopra, Punjab and Edinburgh; Rosa O. J. Clark, Royal Free; G. J. Clarke, Guy's; A. L. Climer and J. R. Colville, St. Bart.'s; F. A. d'Abreu, Birmingham; P. Dalzell, St. Bart.'s; H. B. A. R. Densham, Guy's; M. B. Dixit, Bombay and St. Thomas's; H. R. J. Donald, Manchester; W. J. L. Downing, Middlesex; C. M. Duncan, St. Bart.'s; Lilian P. Edwards, Royal Free; E. G. Evans, Univ. Coll.; I. Q. Evans, St. Bart.'s; M. D. A. Evans, Univ. Coll.; R. S. M. Fisher, Middlesex; G. M. Flemming, St. Bart.'s; B. M. Fonseka, Middlesex; E. S. Fossey, Otago; S. K. Foster, Leeds; D. K. Gaitskell, Guy's; Kathleen E. Gambrell, Royal Free; W. W. Gerrard, Liverpool; S. E. F. Gooding, London; G. H. Greenway, Guy's; V. S. Hariharan, Madras; D. Hay, St. Bart.'s; Geraldine J. G. Hayes, Manchester; Aureval Heaton, Royal Free; H. L. Hoffman, St. Thomas's; R. E. Holmes, London; I. P. G. Howells, St. Mary's; W. V. Howells, London; A. H. Hussein, Cairo and Edinburgh; April D. James, Bristol; N. R. Jeffery, Manchester; J. L. Jekyll, London; D. S. Jones, St. Bart.'s; K. S. Keele, Guy's; S. A. Kelany, Birmingham; H. V. Knight, Cambridge and St. Bart.'s; N. Kramer, St. Bart.'s; E. E. Lewis, St. Mary's; W. E. B. Lloyd, St. Bart.'s; O. V. Lloyd-Davies, Middlesex; F. D. MacCarthy, St. George's; R. W. McConnel, King's Coll.; W. A. R. Mailer, St. Bart.'s; R. G. Mayer, Bristol; R. B. Mayfield, St. Thomas's; T. J. Millin, Dublin; W. J. Moffat, St. Thomas's; A. J. Moffett, Birmingham; E. J. Neill, Cambridge and St. Bart.'s; J. R. Owen, Birmingham; G. A. Y. Parker and A. S. Philps, St. Bart.'s; Betty J. W. Pilsworth, Royal Free; E. S. Pope and C. B. Prowse, St. Bart.'s; T. P. V. Rao, St. Thomas's; W. H. Reynolds, Cardiff; J. A. Rogers, King's Coll.; H. L. Rogerson, St. Bart.'s; A. Said, Birmingham; R. W. Scanlon, St. Thomas's; J. D. Scott, St. Bart.'s; K. M. Seedat, Charing Cross; R. P. W. Shackleton, St. George's; Eileen M. M. Shaw, Westminster; Everell M. Shippam, Royal Free; C. B. Singh, Lucknow; F. J. G. Slater, Cambridge and Durham; C. H. Smith and J. H. Smith, St. Thomas's; J. O. Smith, Melbourne; N. Solomon, St. Bart.'s; L. Tarneja, Univ. Coll.: D. M. Thomas, Cardiff and Middlesex; J. M. Thomas, Cardiff and Univ. Coll.; D. J. Turnbull, London; E. Vitenson, Guy's; G. S. Walker, Univ. Coll.; J. V. Walker, Birmingham; W. W. Walther, Univ. Coll.; J. H. Watkin, St. Bart.'s; G. J. S. West, Bristol; A. J. White, Middlesex; R. L. Whittaker and A. S. Wigfield, Univ. Coll.; E. R. Williams, St. Mary's; J. K. Willson-Pepper, St. Thomas's; Camille Wiseham, Calcutta; Joyce R. Woods and Mary Worthington, Royal Free.

Pathology (New Regs.).—F. I. Ashton, St. Thomas's; D. M. Craig, Middlesex; D. H. A. Edmondson, Liverpool; D. Ezekiel, Charing Cross; R. G. S. Howe, Univ. Coll.; E. Johnson, Manchester; M. Kremer, Middlesex; E. R. G. Passe, London; R. K. Price, St. Bart.'s; B. Ram, St. Thomas's; D. P. Turner, King's Coll.; W. W. Walther, Univ. Coll.; S. J. Wheeler, Guy's; and J. K. Willson-Pepper, St. Thomas's.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Jan. 23rd Mr. H. L. Eason was reappointed representative of the University on the General Medical Council.

The University medal at the M.D. Examination (Branch I Medicine), December, 1928, has been awarded to Horace Joules, of Middlesex Hospital, and the University medal at the M.B., B.S. Examination, November, 1928, has been awarded to Harold Percival Himsworth, of University College Hospital.

Applications will be invited between May 1st and June 15th for grants from the Thomas Smythe Hughes Medical Research Fund for the assistance of original medical research. The Senate will also shortly consider applications for grants from the Dixon Fund for assisting scientific investigations. Further particulars of these funds may be had from the Academic Registrar.

A University studentship in physiology, of £100 for one year, is offered to a candidate suitably qualified for research. Applications must be received in proper form by the Principal Officer by May 31st.

UNIVERSITY OF LIVERPOOL.—Mrs. Adami, widow of the late Vice-Chancellor, Prof. George Adami, has given £100 for the further endowment of the George Adami Prize in Pathology.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—As a result of the terminal examination in the Division of Tropical Medicine and Hygiene of this School, the Duncan medal was awarded to Dr. S. Batchelor.

EUGENICS SOCIETY.—The Galton anniversary dinner will be held at the Rembrandt Hotel, Brompton-road, London, S.W., on Feb. 16th, at 7.15 P.M. The Galton ecture, entitled The Coming of Age of the Eugenics Society, will be delivered by Major Leonard Darwin, Sc.D.

ROYAL MICROSCOPICAL SOCIETY.—A meeting will be held at the house of the society at 20, Hanover-square, London, W., on Feb. 20th, at 8 P.M. Papers will be read on some Effects on Cell Division in vitro of Radium (Dr. R. G. Canti and Mr. F. G. Spear), and of X rays (Miss S. F. Cox). Mr.F. G. Spear will also describe an Effect of Low Temperature on Cell Division in vitro, and demonstrations will be given in connexion with these communications.

ST. ANNE'S HOME SCHOLARSHIP.—The Council of Epsom College will shortly elect a girl to a St. Anne's Home Scholarship of £52 a year. Candidates must be fully 7 years of age and not over 12 years of age on May 1st next, and must be orphan daughters of medical men who have been for not less than five years in independent practice in England or Wales. Application must be made by March 8th, on a form to be obtained from the Secretary of the College, at 49, Bedford-square, London, W.C. 1.

VOYAGE D'ÉTUDES MÉDICALES.—The twenty-second tour of the V.E.M. to French watering places will take place in the Alps during the first fortnight of September, 1929, under the leadership of Professors Paul Carnot, Maurice Villaret, and A. Piéry. After visiting the Faculty of Medicine at Lyons the party will assemble at Vals-les-Bains. The tour will be made by motor coach from Briançon to Evian-les-Bains, where it ends. The spas of the "Briançonnais," "Dauphiné," and "Savoie" will be visited in succession. The detailed programme and cost of the tour will be published later, but further information may now be obtained from Madame Juppé-Blaise, Federation of the Health Resorts of France, 1, Gordon-square, London, W.C. 1.

"THE ANTISEPTIC": SILVER JUBILEE.—Twenty-five years ago the *Antiseptic* was started to meet the needs of the medical profession in South India for scientific medical information by the Hon. U. Rama Rau and the late Dr. T. M. Nair. The former, who is now the editor, has written the story of the journal through a quarter of a century, and has sent us an advance proof of his essay which will appear in the Silver Jubilee issue of the *Antiseptic* in April next. The whole policy of the journal need not be endorsed, while we approve its whole-hearted desire to promote medical reform in India, and the following quotation is a good example of the editor's practical outlook: "The medical profession, in their dealings with the lay public, have a hard time in convincing them of the benefits of fresh air, pure water, nutritious food, good exercise, sound sleep, and a host of other things which are indispensable not only to cure them of their maladies, but also to prevent them from contracting fresh ailments. The lay public consequently require to be educated, too, in matters of health and hygiene, if the medical profession should claim absolute success in their career."

In describing the activities of the journal during the past 25 years, the writer summarises the difficulties under which the I.M.S. worked at the commencement of the wentieth century, and explains the position of the subordinate medical services and their need for reform, pointing out the various changes which the *Antiseptic* considered necessary and which in some cases it may congratulate itself on having successfully brought about. Efforts to put down quackery, to provide the better staffing of the Madras General Hospital, to secure the reorganisation of the subordinate medical department of the Madras Presidency, and the subject of hospital abuse were also matters in which the *Antiseptic* has been strenuously concerned, while it has exhorted members of the medical profession to take a larger part in public life, there being need for more medical men in municipalities, district boards, and legislative councils. "A medical man becoming minister of medicine and public health in a province will be the greatest blessing to the people."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT (SCOTLAND) BILL.

THE House of Commons went into Committee on the Local Government (Scotland) Bill on Thursday, Feb. 7th, Mr. J. F. HOPE (Chairman of Committees) in the chair.

Power of Delegation to Town Councils of Small Burghs.

On Clause 13 a Government amendment was agreed to providing that a county council might, on such terms and conditions as the councils concerned might agree to, appoint the town council of any small burgh, or the district council of a district within the county, or a joint committee of such a town council and district council of which the members of the county council for the burgh and district should be members, to act as agents of the county council to carry out locally with certain exceptions functions vested in the county council. The excepted functions were those relating to education and police, and it was further provided that a function relating to any form of medical or surgical treatment should only be delegated with the approval of the central department.

The clause was added to the Bill by 195 votes to 102.

Schemes for Administration of Functions.

On clause 14 Major ELLIOT (Under-Secretary of State for Scotland) moved a lengthy amendment which included the following:—

"An administrative scheme may provide that any assistance to which this Sub-section applies, which might after the commencement of this Act be provided either by way of poor relief or by virtue of any enactment other than the Poor-law Acts, shall be provided exclusively under and by virtue of the enactments other than the Poor-law Acts and not by way of poor relief, but nothing in this Sub-section or in any scheme shall diminish or otherwise affect the duty of the council to provide relief for the poor.

"The assistance to which this Sub-section applies shall be the maintenance and treatment of sick persons, including, without prejudice to the said generality, persons suffering from any infectious or other disease, or lunatics or persons mentally deficient, or the provision made for the health of expectant mothers, nursing mothers, or children under five years of age or for blind persons, or for the feeding, clothing, and treatment of school children.

"Every administrative scheme relating to education made by the council of a county within which a large burgh is included for the purpose of education shall, unless the county council and the town council of the large burgh otherwise agree, make provision whereby for the purpose of the medical inspection, supervision, and treatment of the children attending the schools within the burgh, the county council shall utilise to such extent, and on such terms and conditions as the councils agree or, failing agreement, as the Department of Health determine, the medical and nursing staff of the town council, and the clinics and hospitals under the control of that council, and every such scheme which shall be made by the county council, and approved by the department only after consultation with the town council shall be binding upon the town council.

He said that this amendment was of very considerable importance, and would, he thought, be welcomed in all parts of the Committee. It provided for the break up of the poor-law, and it was to be taken in conjunction with a new clause, which would be moved later, dealing with the wide extension of hospital facilities and the provision of hospital facilities other than under the Poor Law Acts for sick persons in cities and counties. There was at present a great bundle of duties of most varying kinds applied to persons in varying circumstances wrapped up together under the heading of the poor-law. This dealt more particularly with one group, that of the sick. This was one of the steps for which it was worth while introducing the Bill. The new clause to which he had referred was most important. It was a step which had been recommended by many committees, and it had been unanimously pressed upon the attention of the Government. It was another forward step in the history of public health in Scotland.

Mr. J. STEWART said that he agreed that there was good in this amendment, but he regretted that the Government had not taken this opportunity to consolidate public health and make it a unified treatment, taking away any degrading conditions, so that it would be as free as the present method of dealing with infectious diseases was free. Under this provision a man who was suffering from epilepsy, acquired through no fault of his own, or suffering from cardiac disease, would be compelled, if he was able, to pay for treatment, and if he was not able his child, or someone else who was connected with him in a degree which made the burden legal, would be compelled to pay. He (Mr. Stewart) hated this proposal, and he wished that every member of the Committee hated it as he did.

After considerable debate,

Mr. WESTWOOD moved an amendment to the amendment which would have the effect of making the Government's proposals mandatory and not permissive.

Sir J. GILMOUR (Secretary of State for Scotland) said that it was not possible to make the proposals purely mandatory. They would enable a local authority to produce a scheme, after consultation with all the voluntary institutions in its district, to take into poor-law institutions cases that were at present outside that system. It opened a way to the complete revision and break up of the present system.

The amendment to the amendment was negatived by 197 votes to 107, and the Government amendment was agreed to.

Clause 14 was added to the Bill.

THE LOCAL GOVERNMENT BILL.

On Tuesday, Feb. 12th, the Local Government Bill was considered on Report.

Administrative Schemes.

On Clause 4 Mr. WITHERS moved an amendment providing that a county council, in the preparation of any scheme relating to hospitals, should consult with the representative of the voluntary hospitals in the area, with a view to coöperation in the treatment of the sick and the avoidance of overlapping. He said that he wished to secure that there should be consultation between the Public Assistance Committees when formed and the voluntary hospitals. His object was to provide the most efficient service for the sick when the scheme came into operation. The voluntary hospitals had a very high standard of efficiency in their technical work, and there was an admirable spirit behind that work. When the county councils took over the local infirmaries it was very important that there should be coöperation between what would be the county council hospitals and the voluntary hospitals. Otherwise there would be overlapping, and trouble would arise. It must be disastrous to the voluntary hospitals if the impression was given that those two classes of hospitals were in competition. It was very important that they should work together in harmony and that it should be understood that the one was not going to supersede the other.

Major GLYN seconded the amendment.

Mr. CHAMBERLAIN (Minister of Health) said that any county council in preparing a scheme must have regard to the voluntary hospital provision already existing in the area. It was obvious that no scheme which proposed to deal with the hospital services of an area could really be adequate unless it took account of existing accommodation in the voluntary hospitals. He was, therefore, in full sympathy with the general idea of Mr. Withers that there should be consultation and coöperation between the two classes of hospitals; but he did not think it would be possible to insert this particular amendment. If they were to provide for consultation with representatives of the voluntary hospitals, logically they could not stop there. There were other voluntary associations doing work on parallel lines with some of the work which it would be the duty of the county councils to perform, and if they were to consult with the representatives of the voluntary hospitals it would only be logical to say that they must consult also with representatives of those other associations. Another practical difficulty was that neither the voluntary hospitals nor those other bodies were organised. There was no system by which they could as a body consult with the county council, and therefore to make that a statutory provision would be a mistake. His view was that consultation and coöperation would take place between the voluntary hospitals and the public authorities, but it would not be acceptable to the local authorities if Parliament were to try to lay down precisely how that consultation and coöperation should be carried out.

Mr. E. BROWN said he regretted that the Minister of Health could not accept the amendment. It was very important that the voluntary hospitals should be considered in any scheme of reorganisation.

Major GLYN said that in rural areas a very large number of workers had long been contributing each week to the voluntary hospitals, and it would be hard upon them if the scheme did not take into account the enormous amount of work which had been done in consequence of their contributions. Those interested in hospital work felt that some organisation—even if it had to be created ad hoc—ought to be taken into consultation in connexion with this scheme.

Mr. WEDGWOOD BENN, in supporting the amendment, pointed out that under the safeguarding provisions the Government taxed drugs used by hospitals. Two days ago a document was published saying that the assessments of hospitals were to be raised.

Sir R. SANDERS said that on almost every county council there was someone who represented the voluntary hospitals and who looked after their interests.

Colonel GRETTON said that, as one who had a great deal to do with the administration of two local hospitals, he wished to urge Mr. Chamberlain to accept the amendment. The large hospitals in the country, no less than those in the Metropolis, ought to be taken into consultation in these matters because they were schools of medicine; they provided the ground where the medical profession received its training, and they would not be superseded by the system which the Minister had set up.

Mr. HARRIS said that the London County Council had already considered this problem so far as London was concerned, and their way was comparatively easy. They had the King Edward Hospital Fund in London, and had an immense opportunity of making something like a perfect hospital system for the metropolitan area.

The amendment was negatived without a division.

VIVISECTION.

On Feb. 7th Lieut.-Commander KENWORTHY presented a petition signed by 9829 persons "praying that the House do prevent the practice of vivisection, believing that it is wrong to inflict pain and disease on living animals."

HOUSE OF LORDS.

THURSDAY, FEB. 7TH.

PROTECTION OF ANIMALS AMENDMENT BILL.

Lord BANBURY moved the third reading of the Protection of Animals (Amendment) Bill.

The Marquess of SALISBURY (Lord Privy Seal) said the Government had been placed in a great difficulty over the Bill. They were unwilling to oppose it, partly out of consideration of Lord Banbury, and partly because its main object was to prevent the odious crime of cruelty to dogs. But from the beginning they were convinced that the Bill was unworkable. Some of the amendments which had been passed made it more unworkable still, and on the whole the Bill was not likely to prove an effective piece of legislation. The procedure of the Bill was not only ineffective but cumbersome. He contended that the procedure was not justified by the small number of cases of cruelty to dogs which occurred in Great Britain.

After some discussion the Bill was rejected on a division by 24 votes to 18—majority against, 6.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 6TH.

Hygiene on British Ships.

Dr. VERNON DAVIES asked the President of the Board of Trade if it was proposed that the joint committee recently set up by the Minister of Health and himself should inquire into the question of hygiene of crews' spaces, with a view to reporting on the sufficiency and efficiency, or otherwise, of the existing sanitary code to secure a reasonable standard of sanitary requirements for all British ships.—Mr. HERBERT G. WILLIAMS (Parliamentary Secretary to the Board of Trade) replied: The question of crew spaces on board ship is within the scope of the joint advisory Committee set up by the Ministry of Health and Board of Trade, and a special series of reports on the subject have been placed before the Committee for their consideration.

Dr. VERNON DAVIES asked the President of the Board of Trade if he had received representations from the Society of Medical Officers of Health, the Royal Sanitary Institute, the Merchant Service Guild, and the Association of Port Sanitary Authorities, stating that the conditions under which merchant seamen were housed on British ships were, from a hygienic standpoint, unsatisfactory and inferior to those on ships of similar tonnage of certain other nationalities; and what reply he had returned.—Mr. HERBERT G. WILLIAMS replied: Representations have been received from one of the bodies mentioned. No detailed reply was sent, but those representations will be considered in connexion with any amendment of the crew space regulations, which are now under review. The conditions on some British ships, especially some of the smaller and older ships, cannot be regarded as satisfactory, and the conditions on some foreign ships are very good; but it is misleading to suggest that crew spaces on British ships generally are unsatisfactory from the hygienic standpoint and inferior to those on foreign ships.

Dr. DAVIES also asked the President of the Board of Trade if he was aware that during 1917 and 1918 the Board of Trade possessed statutory powers to decide the type and position of crews' spaces on British merchant ships; to insist upon the provision of such amenities as two-berth cabins, mess rooms, bath and wash rooms, drying rooms, outside oilskin lockers, and hospital room, as well as to

compel w.c. accommodation as a matter of necessity and without consideration respecting tonnage reductions; that these powers were not at present being enforced; and if he proposed to take any steps to restore these war-time amenities to merchant seamen in British ships.—Mr. HERBERT G. WILLIAMS replied: The statutory powers of the Board of Trade in this matter have not changed, and any changes made in the instructions have been in the direction of requiring a higher standard. I may add that many owners go considerably beyond the minimum requirements.

The Poison Gas Protocol.

Sir ROBERT THOMAS asked the Secretary of State for Foreign Affairs whether he was not prepared immediately to ratify the poison gas protocol of the League of Nations, he would announce through the League that ratification by this country might be regarded as coming automatically into force as soon as the other signatories had ratified it.—Sir A. CHAMBERLAIN replied: It has been announced on more than one occasion in this House that H.M. Government are not prepared to ratify the Gas Protocol unless all the other signatories are ready to do so. The position taken by H.M. Government is thus a matter of common knowledge, and I do not consider that any further pronouncement would lead to any useful results.

THURSDAY, FEB. 7TH.

Maternity and Child Welfare Grants.

Sir ROBERT NEWMAN asked the Minister of Health, with regard to the schemes which had been submitted to the Ministry by county boroughs and other local authorities for building new maternity and child welfare centres, whether in cases where the schemes had been already approved by the Ministry on the principle of a 50 percentage grant, that undertaking would be adhered to by the Ministry, if the local authority so desire it.—Mr. CHAMBERLAIN replied: No, Sir. The grants for maternity and child welfare other than the training of midwives and health visitors will be wholly discontinued after March 31st, 1930, and will be absorbed in the new grants to be given under the Bill.

Cancer Mortality.

Mr. R. MORRISON asked the Minister of Health if he would give the figures, to the last available date, of the number of deaths from cancer of men, women, and children respectively.—Mr. CHAMBERLAIN replied: The most recent figures available are those for 1927, in which year the deaths from cancer in England and Wales were:—

Children under 15 years of age ..	213
Males of 15 years of age and over ..	24,946
Females ,, ,, ,, ,, ..	28,919
Total, all ages and sexes	54,078

Criminal Lunatics.

Sir HARRY BRITTAIN asked the Home Secretary (1) whether, in deciding as to the release or detention of a criminal lunatic, the Home Office was guided solely by medical considerations or if other considerations were likewise included; and whether the opinion of the medical superintendent of the asylum was alone considered or whether that of an independent man was obtained; and (2) whether there were periodical or any examinations of criminal lunatics with a view to ascertaining if they were still of unsound mind and, if so, by whom were such examinations made; and how many, if any, criminal lunatics had during the last ten years been discharged as cured or been transferred to some other home or institution respectively.—Sir W. JOYNSON-HICKS replied: The Secretary of State has regard to all the circumstances. So far as medical considerations are concerned, he is guided mainly by the view of the skilled medical authorities at Broadmoor Criminal Lunatic Asylum—or, if the patient be in a local mental hospital, by the views of the superintendent and of his own medical advisers. All criminal lunatics are constantly under skilled medical observation, and reports on each of them are made to me, both periodically and upon occasion, by the superintendents of the asylums. As the Secretary of State has regard to all the circumstances, and not to medical considerations alone, discharge does not depend entirely upon any single definite factor such as entire recovery or complete cure, nor does transfer from one institute to another necessarily connote cure or recovery. The figures asked for cannot therefore be given.

The Purchase of Radium.

Mr. ROBERT MORRISON asked the Minister of Health, in view of the fact that the Swedish nation had recently purchased six grammes of radium sulphate at an approximate cost of £10,000 per gramme, whether he would inquire into the possibility of a similar purchase being made by his department, thus effecting a saving of £2000 per gramme on the price of £12,000 at present being charged to British purchasers.—Mr. CHAMBERLAIN replied: I have seen press reports to the same effect as the first part of the question. I have no funds at my disposal for the purchase of radium, but the whole question will be considered by the Government when the report of the subcommittee of the Committee of Civil Research has been received.

Geneva Opium Convention.

Sir ROBERT GOWER asked the Home Secretary which of the member States of the League of Nations had ratified the Geneva Opium Convention, and which of them had declined or neglected respectively to do so.—Mr. G. LOCKER-LAMPSON (Under-Secretary for Foreign Affairs) replied: The Geneva Opium Convention has been ratified in respect of all parts of His Majesty's Dominions except the Irish Free State. Of the other members of the League of Nations I understand that the following have ratified, or acceded without qualification:—Austria, Belgium, Bulgaria, Czecho-Slovakia, Dominican Republic, Finland, France, Japan, Latvia, Luxemburg, Netherlands, Poland, Portugal, Roumania, Salvador, and Spain; and the following have signed, or acceded subject to ratification, but have not so far ratified:—Albania, Bolivia, Chile, Cuba, Denmark, Germany, Greece, Hungary, Italy, Nicaragua, Persia, Serb-Croat-Slovene State, Siam, Switzerland, Uruguay, and Venezuela.

MONDAY, FEB. 11TH.

Radium and the Treatment of Cancer.

Mr. ROBERT MORRISON asked the Minister of Health whether it had now been decided to recognise North Middlesex Hospital as the centre available for radium treatment for Middlesex; and, in view of the large mortality from cancer, whether he would take steps to speed up the arrangements necessary so that the work might commence at an early date.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend has approved arrangements under which the Edmonton Board of Guardians will obtain a supply of radium for the treatment of particular forms of cancer at the infirmary of the guardians which is known as the North Middlesex Hospital, and one of the terms of the arrangement is that in so far as the radium may not be in use for persons chargeable to the guardians, it shall be used for similar cases from other unions in the adjacent parts of Middlesex. There has been and will be no avoidable delay on my right hon. friend's part in bringing the arrangements into operation.

Import Duty on Radium Compounds.

Mr. WEDGWOOD BENN asked the Secretary to the Treasury whether radium and radium compounds were at present subject to an import duty; and, if so, at what rate.—Mr. A. M. SAMUEL replied: The item "radium compounds" is included in the list of chemicals liable to a duty of 33⅓ per cent. ad valorem issued by the Board of Trade under Part I. of the Safeguarding of Industries Act, 1921, but these compounds are exempted from duty until June 30th, 1929, by Treasury Order made under Section 10 (5) of the Finance Act, 1926. Radium is not dealt with commercially except in the form of a compound.

TUESDAY, FEB. 12TH.

Nervous Diseases among Telephonists.

Sir ROBERT THOMAS asked the Postmaster-General what number and percentage of girls employed in telephone exchanges in London during the past year had been recorded as suffering from nervous complaints, slight or serious; what was the maximum continuous period of duty during the busy hours of the day; and what was the maximum number of lines allotted to one attendant.—Sir W. MITCHELL-THOMSON replied: A considerable amount of time and Labour would be required to furnish the information asked by the hon. baronet; but I am in a position to give corresponding figures for 1926. In that year, out of 79,712 days of sick leave taken by London telephonists; 4193 days were attributed to neurasthenia, nervous debility, nervous exhaustion, nervous shock, and neurosis; 385 days to neuritis; 1592 days to neuralgia. The total number of telephonists employed was 7051, but there is no record of the number of telephonists who were absent on account of these disorders. The normal maximum continuous period of duty covering the busy hours of the day is three and a half hours. This is sometimes extended to four hours; but the duty in either case includes some time outside the busy period. The number of lines allocated to any one operator varies from 60 to 260, the average number being 120.

Protection against Gases in War Time.

Mr. ROBERT MORRISON asked the Prime Minister whether any scheme would be issued to local authorities and others concerned for the protection of town populations from

chemical gases in future warfare, providing for gas-proof rooms, flushing of streets with appropriate chemicals, decontaminating clothing, and providing first-aid and removals to hospitals; and what steps were being taken to provide the necessary preliminary training in these matters.—Mr. BALDWIN replied: The problem of the protection of the civil population against air attack is being closely studied in all its aspects, including those specifically referred to in the question by the hon. Member. The need for the preliminary training of personnel and for the preparation of full and precise instructions to all concerned is not being overlooked.

Appointments.

COBB, J. H., M.B., B.S. Lond., F.R.C.S. Eng. & Edin., has been appointed Surgeon to the Ear, Nose and Throat Department of Sheffield Royal Infirmary.

MACINTYRE, E. J., M.B., Ch.B. Glasg., Assistant Tuberculosis Officer, Bermondsey.

TAYLOR, W., M.D., Ch.B.,Aberd., D.P.H., County Medical Officer of Health for Salop.

WITTS, L. J., M.D. Manch., L.R.C.P. Lond., Assistant to the Medical Unit of the London Hospital, Assistant Physician to Guy's Hospital.

Paddington Green Children's Hospital: ELLIS, V. H., M.B., B.Chir. Camb., F.R.C.S. Eng., Honorary Surgeon to Out-patients; MCLAGGAN, J. D., M.B., Ch.B. Aberd., F.R.C.S. Eng. & Edin., Additional Honorary Surgeon to Ear, Nose and Throat Department.

Sheffield Royal Hospital: STONE, DORIS M., M.D. Lond.,D.P.H., full time Assistant Pathologist; CALLCUTT, J. SHIRLEY, M.B., Ch.B., Resident Surgical Officer; HYNES, W., M.B., Ch.B., Senior Casualty Officer; PATTERSON, W. J., M.B., B.Ch., and RAINSFORD, C., M.B., B.Ch., House Surgeons; MAXWELL, C. G., M.B., B.Ch., and GUMPERT, T. E., M.B., Ch.B., House Physicians; ALCOCK, W., M.B., Ch.B., and LAVERY, M. B., M.B., B.Ch., Assistant House Surgeons; ROSENFIELD, E., M.B., B.Ch., Ophthalmic House Surgeon; FROGGATT, G. H. V., L.R.C.P., M.R.C.S., Aural House Surgeon; and STEWART, W. J., M.B., B.Ch., Resident Anæsthetist.

Certifying Surgeons under the Factory and Workshop Acts: FLOOD, J. W., L.R.C.P.I., L.R.C.S.I. (Crosby, Lancs); GORDON, J. D., M.B., Ch.B. Aberd. (Bolsover); WILLIS, T. G., L.R.C.P. Lond., M.R.C.S. (Wendron, Cornwall).

Vacancies.

For further information refer to the advertisement columns.

Basutoland.—M.O. £550.

Bath, Royal United Hospital.—H.P., H.S., also Asst. H.S. At rate of £120 and £100 respectively.

Bethnal Green Metropolitan Borough.—M.O.H. £1000.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £120.

Bristol Royal Infirmary.—H.P.'s, H.S.'s, Dental H.S., &c. Each at rate of £80.

Cancer Hospital, Fulham-road.—Director of Electrical and Radio-Therapeutic Dept.

Cardiff Royal Infirmary.—Ophthalmic H.S. At rate of £75.

Cardiff, University College of South Wales and Monmouthshire.—Lecturer and Demonstrator in Anatomy. £400.

Carlisle, Cumberland Infirmary.—H.P. and H.S. Each at rate of £155.

Chester Royal Infirmary.—Hon. Asst. Surgeon.

Dorchester, Dorset Mental Hospital.—Sen. Asst. M.O. £400.

East African Medical Service.—M.O.'s and Health O.'s. £600 and £660 respectively.

Glasgow, Hawkhead Asylum, Crookston.—Jun. Asst. M.O. £275.

Gloucester County Mental Hospital.—Jun. Asst. M.O. £350.

Gloucester, Gloucestershire Royal Infirmary.—2nd H.S. At rate of £100.

Grove Park Hospital, Lee, S.E.—Jun. Asst. M.O. £500.

Guy's Hospital Medical School.—Gull Studentship in Pathology and Allied Subjects. £250.

Hertford County Hospital.—Res. Surg. O. At rate of £250.

Hong-Kong.—M.O. £600.

King Edward Memorial Hospital, Ealing.—Secretary-Supt. £400.

Leeds, General Hospital.—Two Anæsthetists. £25.

Leicester Royal Infirmary.—Preliminary notice of expected vacancies. At rate of £125.

Liverpool, David Lewis Northern Hospital.—H.S. for Orthopædic, &c. At rate of £100.

L.C.C. Mental Hospital Service.—Eighth Asst. M.O. £300.

Lucknow University.—Professorship of Medicine and Physician to King George's Hospital. Rs.1200–50–1400 p.m.

Manchester, Ancoats Hospital.—H.S. Orthopædic. £100.

Manchester and Salford Hospital for Skin Diseases.—H.S. £100.

Manchester, Victoria Memorial Jewish Hospital.—Sen. H.S. £250.

Miller General Hospital for South East London, Greenwich-road, S.E.—Res. M.O., Cas. O., and H.P. At rate of £250, £150, and £125 respectively.

Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H.S. At rate of £100. Also Res. H.P. and Res. H.S. Each at rate of £95.

Newport, Mon., County Borough Mental Hospital.—Asst. M.O. £300.

Northern Rhodesia.—M.O. £600.

Queen's Hospital for Children, Hackney-road, E.—Anæsthetist. £25. Also Res. M.O. £200.

Rampton State Institution for Mental Defectives, near Retford.—M.O. £536 10*s.*

Richmond, Surrey Royal Hospital.—Refractionist. £50.

Rotherham Hospital.—H.P. £180.

Royal Dental Hospital of London, 32, Leicester-square, W.C.—Two Hon. Asst. Anæsthetists.

Royal London Ophthalmic Hospital, City-road, E.C.—Sen. H.S. At rate of £150.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—H.S. Also H.S. for Country Branch at Stanmore, Middlesex. Each at rate of £150.

St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.—Sen. and Jun. Hon. Med. Registrars.

Sheffield, Royal Infirmary.—Vacancy on Hon. Surgical Staff.

Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £175, H.P. £130, Jun. H.S. At rate of £130. Also Cas. O. At rate of £120.

Surrey Administrative County of.—County M.O.H. £1800.

Surrey, County Council.—Asst. M.O. £600.

Torquay, Torbay Hospital.—H.P. £150.

Warwick County Mental Hospital, Hatton.—Jun. Asst. M.O. £350.

West Bromwich and District General Hospital.—H.S., H.P. Also Cas. H.S. Each at rate of £200.

Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—Hon. Sen. Dental Surg., Hon. Dental Surg. Also Asst. Phys. to the Radiological Dept. £50.

Births, Marriages, and Deaths.

BIRTHS.

BUTTER.—At 5, St. Albans-road, N.W.5, on Feb. 8th, to Dr. and Mrs. A. J. M. Butter—a son.

GEBBIE.—At "Branscombe," Davenport Park, Stockport, on 5th inst., to Helen Young Murdoch, M.A., M.B., Ch.B., and Nicolas Gebbie, M.D., D.P.H.—a son.

MOODIE.—On Feb. 9th, at Dudley House, Beaumont-street, W., the wife of William Moodie, M.D., M.R.C.P., of a daughter.

MURPHY.—On Jan. 20th, at The Beeches, Middlewick, the wife of James Murphy, F.R.C.S., of a daughter.

ROBERTSON.—On Feb. 10th, at The Mount, York, the wife of Dr. Douglas A. Robertson, of a daughter.

MARRIAGES.

FAWKES—GREEN.—On Feb. 9th, at St. Matthew's, Ealing Common, Roland Beattie Fawkes, D.S.O., M.A., M.R.C.P., to Beryl Constance, eldest daughter of Mr. and Mrs. Walter Green, of Ealing, W.

DEATHS.

ANDERSON.—On Feb. 2nd, at Twyford, Winchester, Deputy Inspector-General I. H. Anderson, M.D., R.N. (retired), aged 80.

BLACKBURN.—On Feb. 11th, at Arncliffe, Half Edge-lane, Eccles, Harriet, the dearly loved wife of A. E. H. Blackburn, Ph.C., Honorary Visiting Apothecary to the Manchester Royal Infirmary, Salford Royal Hospital, and St. Mary's Hospitals.

GEORGE.—On Jan. 31st, at Margate, Howard Trevelyan George, M.R.C.S., L.R.C.P. Lond., late Senior Chief Assistant, X Ray Department, St. Bartholomew's Hospital, and Hon. Medical Officer in Charge, X Ray Department, St. Andrew's Hospital, Dollis Hill, London.

JACOB.—On Feb. 1st, at St. Helier, Jersey, Archibald Hamilton Jacob, L.R.C.P.I., L.R.C.S.I., late Temporary Captain, R.A.M.C., and Tuberculosis Officer, Essex County Council, aged 61.

MORIER.—On Feb. 2nd, at Maida Vale-mansions, W., Dr. Charles George Drummond Morier.

PATCH.—On Feb. 7th, at a nursing home, Henry Herbert Lloyd Patch, L.R.C.P., M.R.C.S., aged 59.

STEWART.—On Feb. 10th, at Redcliffe-gardens, S.W., Howard Douglas Stewart, M.R.C.S., L.R.C.P., L.S.A. aged 78.

TOLMIE.—On Feb. 5th, at Burnt Ash-road, Lee, Kent, James Alexander Tolmie, M.A., M.B., D.P.H.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE BUNAU-VARILLA SYSTEM OF WATER PURIFICATION.

By T. H. Bishop, M.R.C.S. Eng., D.P.H.,
CHIEF MEDICAL OFFICER, EASTERN BENGAL (STATE) RAILWAY.

THE first report [1] published by Dr. Téchoueyres, director of the Bureau of Hygiene and professor at the School of Medicine of Rheims, regarding the working of the newly installed plant for the treatment of the public water-supply to that city, may be said to have removed the Bunau-Varilla system of purification from the category of experimental to that of proved water treatment methods. Until its installation at Rheims it had been tested only on a small scale under war conditions so that its adaptation to a large municipal service was something of a venture. Dr. Téchoueyres's opinion of its value must be given in his own words. He writes:—

"Je puis déclarer aujourd'hui—après un an d'usage—que la ville de Reims a réalisé l'installation la moins onéreuse, la plus simple et la plus parfaite en adoptant l'appareil auto-javelliseur de M. Philippe Bunau-Varilla."

Following Rheims, a number of other French municipalities are now adopting the process with equally satisfactory results, and this increasing popularity is additional proof of its efficiency. It is probable, therefore, that many, besides those professionally occupied with water purification, may find interest in a brief account of this new departure which is sufficiently revolutionary in principle to suggest a reconsideration of many older methods.

The special features of the system cannot be stated more clearly than Dr. Téchoueyres has given them in his report, where he claims that "the originality of the method of M. Bunau-Varilla lies not only in the use of an automatic apparatus but also in the employment of effective doses of sodium hypochlorite which are well below the strength of such as may be perceived by the taste; that, in short, it is capable of purifying a water without depriving it of its natural agreeable qualities."

The Story of its Origin.

Before proceeding to describe the process it will be convenient to refer briefly to the circumstances in which it was devised, which emphasise the technical ability, enterprise, and courage of its author.

During the disastrous autumn of 1916, when France was exploiting every resource to minimise the depletion of her Forces in the gallant struggle to hold the enemy before Verdun, Commandant Philippe Bunau-Varilla, a civil engineer of considerable repute in his profession, found himself responsible for the water service of the 2nd Army which constituted the Verdun defence. The regulations for treating the field water-supplies had been published in a general army order and, as in the case of the Horrock formula, used by British sanitary units, prescribed a dosage calculated to ensure the presence of available chlorine after preliminary absorption tests had been made. The result seems to have been even less appreciated by the French troops than by the British, for, although the average dose of the disinfectant was only 0·06 parts per million greater, the attitude of the men for whose drinking-water supplies he was responsible thoroughly convinced Commandant Bunau-Varilla that the official instructions in regard to this matter could not be carried out. Yet, on the other hand, there could be no possible doubt about the necessity for purification, as samples from the wells adjacent to the front line—the only possible sources of supply—showed the presence of colon bacilli in alarming numbers.

One can readily appreciate the gravity of such a situation, and it is not surprising that it led an officer as zealous and capable as Commandant Bunau-Varilla to thoughtful speculation concerning this method of water purification. Could safety not be attained without coincident nausea? Were the massive doses which produced such a result entirely necessary? The terrible casualties incidental to the defence operations seem to have provided the opportunity for obtaining answers to these questions. An evacuation hospital was required at Fleury-sur-Aire, and its personnel included the chief of the medical laboratory of the 2nd Army—Major Cathoire. To him Commandant Bunau-Varilla carried his problem, suggesting a series of experiments on polluted water samples to ascertain the bactericidal action of minute doses of available chlorine ranging from one decimilligramme per litre up to the minimal official dose of one milligramme per litre. Major Cathoire confesses that he considered the suggested investigation foredoomed to failure in so far as it might be expected to warrant any departure from the official practice, but the zeal and persistence of his brother officer prevailed and he undertook the tests. His earliest results aroused his own interest in the inquiry as they showed an almost complete destruction of the colon bacilli (1000 per litre) in the Fleury-sur-Aire water with a dose of *eau de Javelle* giving 1·0 decimilligrammes of available chlorine, and this destruction became complete when the available chlorine was increased to 1·3 decimilligrammes per litre (0·13 parts per million). Similar experiments were made with samples of the Bar-le-Duc water which contained 33,000 colon bacilli per litre, and here the results were even more remarkable, as complete disappearance of the colon bacilli was secured with a dose of 0·8 decimilligrammes of available chlorine (0·08 parts per million).

The investigation and the results obtained were reported to army headquarters and, without any loss of time, Commandant Bunau-Varilla proceeded to reorganise the water purification arrangements at the 2nd Army depôts. The army water plant was adapted for the use of "doses infinitesimales" and an ingenious contrivance added which secured an automatic supply of the reagent.

Believing that the limit of the bactericidal action of *eau de Javelle* had not been reached, further experiments were made with the water-supply to the Chateau of Souilly—the seat of the headquarter's staff of the Verdun army—and complete elimination of the small colon bacilli content was attained with a dose of one-fiftieth of a milligramme of available chlorine per litre (0·02 parts per million).

Mr. Bunau-Varilla had the misfortune to be seriously wounded shortly afterwards, but the report he had submitted led to the appointment of a scientific commission which repeated and confirmed the experiments of Major Cathoire so far as these dealt with samples of clear water. The commission then proceeded to make similar tests on samples of water charged with organic matter and muddy, with the result that they did not obtain complete destruction of all colon bacilli, but noted a constant marked diminution in their number. The work of this commission was closely followed by the chief of the military epidemic service Prof. Dopter, who later, conjointly with Prof. Rieux, of Val-de-Grâce, made the report public in a communication to the Academy of Medicine of Paris, where, after a description of the improvements which Commandant Bunau Varilla had made in the army water treatment apparatus they stated: "This apparatus has been in use at all the water depôts established by the 2nd Army, and at some of those of the 4th Army, and although the amount of free chlorine provided for by the author of the process is so extremely small the system has given entire satisfaction."

The prolonged and serious illness of Mr. Bunau-Varilla probably prevented any immediate further exploitation of his valuable work, and it seemed improbable at one time that the process would ever be applied on a large scale, when by a stroke of good fortune it came to the notice of Dr. Téchoueyres who, as director of the bureau of hygiene of Rheims, was faced with one of the many health problems which the war created for France. The devastation caused by the prolonged and fierce bombardment to which Rheims was subjected made it necessary for the returning population to select sites for their new dwellings further afield and, in fact, suburbanisation occurred to such an extent that the wells from which the city had hitherto drawn a quite satisfactory water-supply now came within the area of pollution. Keenly alive to the danger which these altered conditions threatened, Dr. Téchoueyres brought the matter to the attention of the municipal authorities. "On chercha," he writes, "un procédé qui guarantît les eaux potables contre une surprise de pollution tout en leur laissant leur goût agréable, et en ne créant aucune charge pécunaire excessive." As mentioned, good fortune brought him into touch with Mr. Bunau-Varilla who undertook to design a plant embodying the principles of his system for the Rheim supply of 3 to 4,000,000 gallons a day. When it is stated that the plant which has now been working for two years cost only 3000 francs (say £30)* to instal and about sixpence per 1,000,000 gallons for running charges, it may be admitted that on the score of economy the choice of process could hardly have been bettered.

Description of the Apparatus.[2]

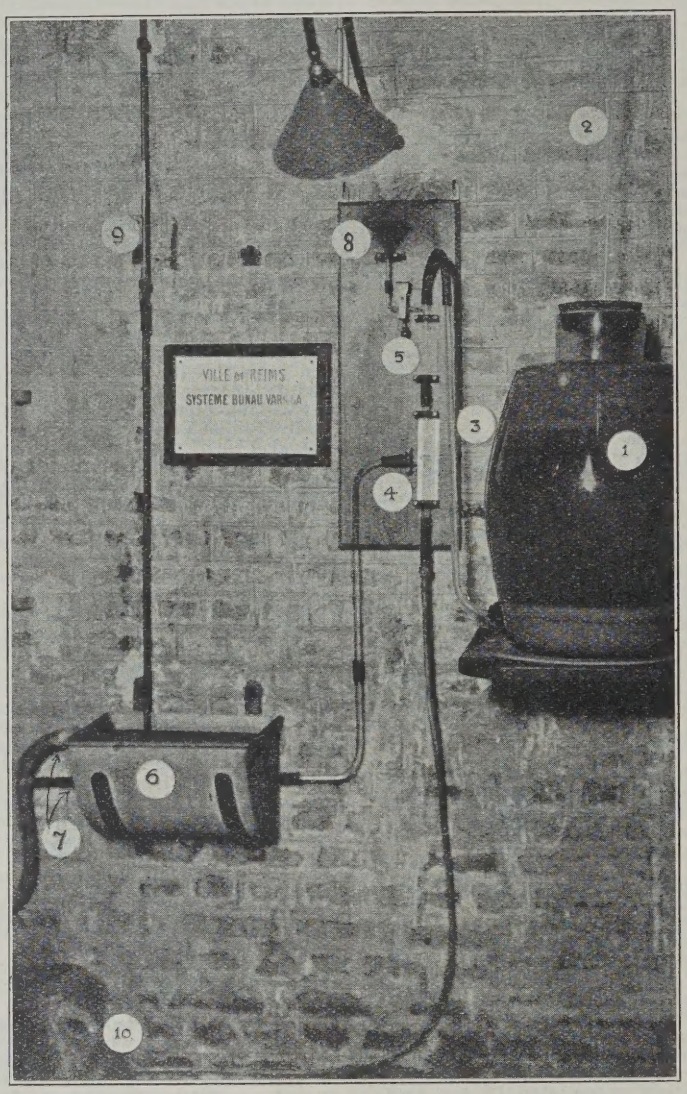
The accompanying photograph will show the simplicity of the mechanism. The partshave been numbered for easy reference.

The apparatus consists of a glass barrel reservoir (1) for diluted *eau de Javelle* solution,† the necessary amount of dilution being determined by the formula given. The reservoir is corked but an air-inlet tube (2) allows atmo-

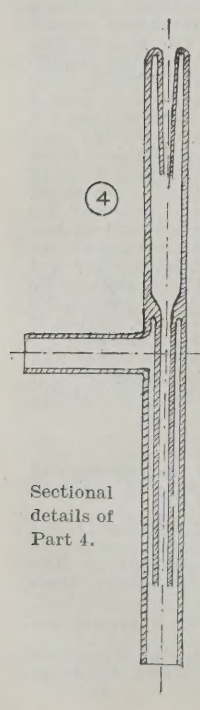
* Mr. Bunau-Varilla has neither patented his apparatus nor accepted any fee for its design.

† *Eau de Javelle* is a solution of NaCl and NaOCl, of variable strength, which can be procured in almost every village in France.

spheric pressure to act on the fluid level at the same time that it minimises loss of strength of the reagent. In operation the fluid is conducted through a bent glass tube (3) to a point (4) termed the *bifurcateur trompe*, where it meets a stream of water which dilutes it further, so that on reaching the water main into which it is discharged a dose of available chlorine of 1 decimilligramme per litre (0·1 parts per million) is provided. The relative quantities of reagent and diluent are also controlled by causing the former to pass through two calibrated constrictions (5) of 5/10 and 8/10 mm. respectively. The stream of diluting water is delivered at constant pressure after passing through an open trough (6), the level of which is maintained by the device of a surplus feed and two waste outlets (7), one at a higher level than the other. An arrangement for bringing a minute quantity of HCl to dissolve any solid particles which may come over and block the flow of the reagent is provided (8), but this technical difficulty does not appear to arise in actual practice. Automaticity is ensured by linking up the pump starter with a valve on the pipe through which the water supplying the pressure-regulating trough passes. The flow throughout the apparatus is excited by suction induced at the point (10) where the disinfecting fluid finds entrance to the water main.



The Bunau-Varilla system installed at Rheims.



Sectional details of Part 4.

My inspection of the Rheims plant left the impression of an extremely simple, effective, and easily supervised contrivance.

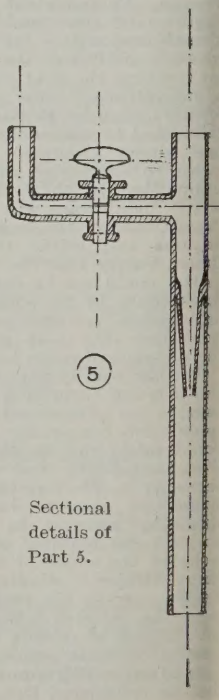
Special Features of the Process.

It is probable that when the urgent need for obtaining a safe and acceptable drinking water-supply for the Verdun troops caused Mr. Bunau-Varilla to speculate regarding the dose of chlorine which was required for purification he was unaware of the work which had been done by other investigators in regard to the same problem and, possibly, he has congratulated himself since on his opportune ignorance, for there can be few problems which have evoked such widely differing opinions. At the one extreme is Nissen of the Berlin Hygienic Institute, whose experiments required 420 parts per million of available chlorine to produce sterilisation in one minute, and half that amount to effect it in ten minutes, and at the other extreme is the careful work of Race,[3] of Ottawa, who found that a suspenon of 1000 colon bacilli per c.cm. could be reduced to the 2 bacilli standard in ten minutes, in a water from which organic matter was absent, with 0·1 parts per million. For the London water-supply the dose employed is slightly more than 0·5 parts per million, but in this case the reagent is added prior to filtration.[4] The practice of Mr. Dienert, of the Paris Water Service, is to make a preliminary absorption test and then to add 2 decimilligrammes of available chlorine per litre. This is for a contact period of three hours. The methods followed in the treatment of other large public supplies further indicate the diversity of opinion which exists, but the story of the legal battle which was occasioned by the experiments on the Boonton portion of the supply to Jersey City, U.S.A., would probably have heartened Mr. Bunau-Varilla had he known it in those anxious days. As long ago as 1908 Mr. G. A. Johnson and Prof. Leal, being associated in a scheme for treating the Boonton supply, followed a policy of employing gradually reduced doses until they had decreased these from an initial dose of 1·4 parts per million of available chlorine to 0·2 parts per million. At this point the city authorities seem to have taken fright and the law was invoked. The judgment is worth quoting from.

"From the proofs taken before me," announced the court, "of the constant observation of this device I am of opinion and find that it is an effective process which destroys in the water the germs, the presence of which is deemed to indicate danger, including the pathogenic germs, so that the water after this treatment attains a purity much beyond that attained in water-supplies of other municipalities. The reduction and practical elimination of such germs from the water was shown to be substantially continuous."

Possibly had this story been better known generally, and more work done on the lines followed by the Rheims investigators, the system of Mr. Bunau-Varilla would not have had to wait so long for its début.

It is to be observed, in appreciation of the part which Dr.



Sectional details of Part 5.

Téchoueyres has played in the evolution of this process, that its adoption for the Rheims public supply was not decided upon without very careful consideration, and some noteworthy experimental work has been done at the Reims public health laboratory which, in his opinion, has established several important facts serving to explain the process scientifically. The first of these facts is the proof of persistence for a long period of effective, if minute, dose of available chlorine irrespective of the relative amounts of organic matter and disinfectant which may be brought into contact in a water sample. As he states it "the quantity of chlorine which is fixed by a water is not, as one might suppose, determined by the quantity of organic matter present."

This statement runs directly counter to the presumption on which absorption tests are based. It would be assumed from the latter that the majority of waters, by reason of their organic content, would account for more than the amount of chlorine available in the Bunau-Varilla process, but the Rheims experiments indicate otherwise. They suggest instead, that the organic gourmand may always be relied upon to leave a few crumbs for the more reticent guests. The details of a series of experiments will illustrate this.

A litre of Marne water (organically impure) was placed in each of three flasks and to these were added sodium hypochlorite giving 0·5, 3·0 and 6·0 milligrammes of free chlorine respectively. Half an hour's contact was allowed and the contents of the flasks were then tested for the quantity of chlorine which had been fixed by the litre of water in each. In the first flask to which 0·5 milligramme had been added the proportion of chlorine fixed, to the original dose, was 86 per cent., in the second flask 47·3 per cent., and in the third flask 29 per cent.

A second series of experiments showed that if the organic gourmand was fed in three successive stages, at half-hourly intervals, with sodium hypochlorite providing respectively 1/2, 3 and 3 milligrammes of available chlorine, the proportions fixed were 86, 50, and 49·6 per cent.

Dr. Téchoueyres's observations on these experiments are, first, that the proportion of chlorine which is fixed varies with the quantity offered, and, secondly, that successive additions cause a greater absorption than a single meal, and both prove that the results cannot be explained on the basis of chemical interaction.

A second fact which the Rheims workers claim to have established is the difference in vulnerability to *eau de Javelle* of organisms of the typhoid group and the colon bacilli—the latter, in their experiments, proving the more resistent. It is to be noted that other investigators have not been able to come to so definite an opinion on this point, but the desirability of such an assurance is apparent in view of the margin of safety which it affords where the colon bacillus standard of purity is adopted.

The third fact which the Rheims observations have emphasised is the effect which agitation and prolonged contact have upon the degree of purity attained. In this connexion details are given which indicate that even the feeble doses employed are actually or potentially available for more than 24 hours, and that during this period their destructive action continues. This is corroborated by other observers, and as regards contact by the interesting judgment which has been quoted in the Boonton case. As regards "brassage" or agitation, Dr. Téchoueyres considers this as of equal value, at least, with duration of contact.

The Bactericidal Ray Hypothesis.

Whilst it is not essential to a description of the water purification system devised by Mr. Bunau-Varilla, this note on certain features of the work which has been incidental to its evolution would be incomplete without a brief reference to the interesting hypothesis which has been adopted by the authors in explanation of the action of doses of chlorine which are so chemically inadequate and yet so practically effective. To emphasise this inadequacy Dr. Téchoueyres postulates the current theory of the action of sodium hypochlorite in the purification of water, represented by the formula :—

$$NaOCl + H_2O = HCl + NaOH + O$$

or, in the presence of a catalyser,

$$NaOCl = NaCl + O$$

—i.e., an atom of oxygen, with the atomic weight of 16, is liberated by an atom of chlorine with the atomic weight of 35·5. Noting that the Rheims water contains organic matter equivalent to about 1 milligramme of oxygen, he remarks that obviously twice this amount of chlorine should be required to replace this alone, whereas in actual practice the addition of a twentieth of the quantity proves to be an effective bactericide. From so irreconcilable a supposition the authors fall back on the hypothesis formulated by Mr. Jean Perrin (published under the title "Matière et Lumière" in the *Annales de Physique* in 1919) that all chemical reactions and, generally speaking, all changes in the physical state of bodies give rise to the emission or reception of particular rays. Arguing on this assumption Mr. Bunau-Varilla and Dr. Téchoueyres suggest that the rupture of the molecule of sodium hypochlorite, when added to water, produces an emission of rays analogous to ultra-violet rays much in the same manner that luminous rays are incidental to ordinary combustion, and that such special rays are the true lethal agent. They state that they have obtained a certain amount of confirmation of this hypothesis.

This brief account of a prolonged investigation which cannot be without interest to all engaged in water purification will show that there are debatable features—bacteriological standards, technique, general conditions—all are variable, and even the reagent employed is not the same as used in this country, but when all these have been discounted two incontestible facts remain: first, that the Bunau-Varilla system is adequate, in practice, to the production of a safe public water-supply; and, secondly, that it is superior in point of economy, simplicity, and absence of objectionable results to many processes now in use.

My acknowledgments are due to Profs. Besredka and Calmette, of the Pasteur Institute, from whom my earliest information of the Bunau-Varilla system was obtained, and to Dr. Téchoueyres for his courtesy in demonstrating and explaining it and the details of the work which has been done in connexion with it.

A DESK MANUAL.

Mr. J. B. Thornhill has reproduced the Hippocratic Oath [1] in incised white letters on blackwood panel, to be placed on the doctor's desk. The panel is 9¼ inches by 7¼ inches—i.e., it is roughly double the size of an ordinary sheet of writing paper—and the width of the lettering is 5¼ inches, giving an inch margin between the bevelling and the lettering, which is executed in five well-balanced paragraphs dealing with the doctor's relations to his patients. Mr. Thornhill has ignored the duties of the doctor to his brother doctors, his rendering being as follows :—

THE DOCTOR'S OATH.

I will follow the system of regimen which, according to my ability and judgement, I consider for the benefit of my patients and abstain from all that is mischievous and deleterious.

I will give no deadly medicine if asked, nor will I suggest such plan; so too, I will not procure abortion.

With Purity and Holiness I will pass my life and practise my Art.

Into whatever houses I enter I will go into them for the benefit of the sick and abstain from all voluntary actions of mischief and corruption.

Whatever in professional practice or outside it in the life of the world I see or hear, which ought not to be spoken abroad, I will not divulge, for such things should be kept secret.

The idea of the panel is to show the layman the earnestness and discretion of the medical profession, whose ideals few members of the general public realise.

ELECTROTHERAPY AFTER PROSTATECTOMY.

To the Editor of THE LANCET.

SIR,—A man of 65 had his enlarged prostate removed by the suprapubic route as it was producing retention overflow. He was also in a state of low resistance owing to a combined degeneration of his spinal cord. Fourteen days after the operation the wound was unhealthy and septic, and showed no signs of closure. He was given daily local massive doses of tungsten arc ultra-violet light to the wound for five days, and general irradiation to different parts of his body in ordinary doses. High frequency with the vacuum electrode was also applied to the wound itself. Within four days the whole area had become clean, and within 14 days the wound had closed up.

I am, Sir, yours faithfully,

Sheringham, Norfolk, Feb. 9th, 1929. H. W. HALES.

Messrs. Armour and Company, manufacturers of Glanoid medicinal products of animal origin, have removed their pharmaceutical department from Kingsway to Armour House, St. Martin's le Grand, London, E.C. 1.

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(*Continued from p. 320.*)

THE following official bulletins have been issued:—

THURSDAY, FEB. 7TH. 11.45 A.M.

Though the stage of convalescence has not yet arrived, His Majesty's progress is such that the proposed change to the south coast is now desirable. (Signed by Sir Stanley Hewett, Sir Hugh Rigby, Sir Farquhar Buzzard, Sir Humphry Rolleston, and Lord Dawson of Penn.)

FRIDAY, FEB. 8TH. 12.15 P.M.

The progress of His Majesty the King, though slow, continues. A radiogram taken this morning confirms the clinical evidence that the condition of the lungs is now normal. If the weather permits, His Majesty will leave the Palace at 10.30 to-morrow morning for Craigweil House. (Signed by Sir Stanley Hewett, Dr. H. Graham Hodgson, and Lord Dawson of Penn.)

SATURDAY, FEB. 9TH. 6 P.M.

His Majesty the King travelled to Craigweil House without undue fatigue, and the general condition is satisfactory. (Signed by Sir Stanley Hewett and Lord Dawson of Penn.)

SUNDAY, FEB. 10TH. 4 P.M.

His Majesty the King had a good night, and his improvement continues. (Signed by Sir Stanley Hewett and Lord Dawson of Penn.)

(*Continued from previous column.*)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Feb. 18th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.
FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

ROYAL NORTHERN HOSPITAL, Holloway-road, N. (Intensive Week.)

MONDAY, Feb. 18th.—2.15 P.M., Mr. Kenneth M. Walker: Chronic Infection of the Urinary Tract. 3.15 P.M., Dr. W. J. Adie: Some Sudden Attacks of Nervous Origin.
TUESDAY.—2.15 P.M., Mr. F. D. Saner: The Repair of Fractures. 3.15 P.M., Dr. E. G. B. Calvert: Points of Practical Importance in Glycosuria and Albuminuria.
WEDNESDAY.—2.15 P.M., Mr. N. A. Jory: Chronic Nasal Obstruction. 3.15 P.M., Dr. H. C. Semon: Demonstration of Selected Cases.
THURSDAY.—2.15 P.M., Dr. W. H. McKinstry: Pathological Specimens. 3.15 P.M., Mr. C. S. Lane-Roberts: Some Disorders at the Menopause.
FRIDAY.—2.15 P.M., Dr. Bruce Williamson: Demonstration of Selected Medical Cases. 3.15 P.M., Mr. T. T. Higgins: Some Points in the Ætiology and Diagnosis of Gall-stones.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Feb. 18th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Collier: Cerebral Vascular Disease.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Donald Armour: Surgery of Compression Paraplegia.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: The Demonstration of Cerebellar Lesions.
FRIDAY.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of the Nervous System. 2 P.M., Dr. Adie Out-patient Clinic. 3.30 P.M., Dr. Walshe: Multiple Neuritis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, Feb. 22nd.—3.30 P.M., Mr. Hay: Spectacles Ancient and Modern.

ST. MARY'S HOSPITALS POST-GRADUATE LECTURE Manchester.

FRIDAY, Feb. 22nd.—4.30 P.M. (at the Whitworth-street West Branch), Mr. Morley: The Treatment of Birth Injuries.

Hunterian Lecture

ON THE TREATMENT OF SOME ACUTE ABDOMINAL DISORDERS.

Delivered before the Royal College of Surgeons of England on Feb. 4th

BY R. J. MCNEILL LOVE, M.S. LOND.,

ELLOW OF THE COLLEGE; LATE SURGICAL REGISTRAR AND ASSISTANT AT THE LONDON HOSPITAL; ASSISTANT SURGEON TO THE METROPOLITAN HOSPITAL.

I.—ACUTE APPENDICITIS.

I OFFER no apology for introducing such an pparently threadbare subject as acute appendicitis, r, according to the Registrar-General's returns, early 3000 deaths occur every year in this country om this condition. When one remembers that this ll is taken chiefly from those in the second and third cades, then this mortality is even more perturbing. In spite of improving diagnosis and earlier opera- on, the annual mortality remains at a little over per million. Probably, as Rendle Short has cently emphasised, one of the influences which unteracts improved surgical measures is the diminish- g amount of cellulose consumed in civilised diets. one period of the war I was medically responsible r the health of an Arab town and district with a pulation of about 15,000. The staple diet of the ople consisted of dates, unpolished rice, and barley ead, and during my stay of six months I saw no se of appendicitis. Under corresponding circum- ances in a civilised community one would have pected about half a dozen cases.

When I returned from the war to take up the ties of surgical registrar at the London Hospital e following state of affairs intruded itself upon my tice—that in some wards every case of acute pendicitis was treated by an emergency operation, ilst in other wards cases in which mischief had pparently spread beyond the appendix were treated pectantly. Such discrepancy demanded investiga- on, and consequently I reviewed all the cases treated the London Hospital from 1920 to 1924, totalling 18.[1] Ignoring the early cases in which the infection still limited to the appendix and which are univer- lly treated as a surgical emergency, an analysis the remainder indicated that cases treated with scrimination, and not according to rule of thumb, owed a lower immediate mortality and a much less rmidable proportion of complications and sequelæ an the cases operated upon as soon as seen.

TABLE I.

	LONDON	ST THOMAS	MANCHESTER	TOTAL
	— EXPECTANT —			
CASES.	341	214	52	607
DIED.	12	9	3	24
MORTALITY.	3·5%	4·2%	5·7%	3·8%
	— IMMEDIATE —			
CASES	1667	901	128	2706
DIED.	98	76	6	180
MORTALITY.	5·8%	8·4%	4·6%	6·7%

Partly, I believe, as a result of these statistics and nclusions concerning this subject, interest and scussion were rearoused, and 1115 cases at St. homas's Hospital were reviewed and published.[2] ice then intermittent correspondence has appeared in medical journals, and only last year a review appeared of 245 cases treated at the Manchester Royal Infirmary.[3] It has been said that there are three kinds of lies—the ordinary lies, black lies, and statistics. However, when statistics assume massive proportions and are compiled from different sources, then discrepancies due to chance and coincidence correspondingly diminish. I have accordingly combined the figures from the London Hospital, St. Thomas's Hospital, and the Manchester Royal Infirmary. The figures given in Table I. do not include early cases in which the disease was limited to the appendix, and the summary from the three hospitals shows that 607 cases were treated on expectant lines with a mortality of 3·9 per cent., and in 2706 cases in which immediate operation was performed the mortality was 6·7 per cent.

Treatment of General Peritonitis.

Cases of acute appendicitis may be divided clinically into three groups—the early cases, those in which the general peritoneal cavity is involved, and intermediate cases in which the infection has spread beyond the appendix but is limited to the right iliac fossa. We need not consider the early cases which are properly dealt with as emergencies. I shall only briefly refer to the second group—that is, those of general peritonitis. In these cases a comparatively high mortality is to be expected, owing partly to the virulence of infection as compared with the patient's resistance, which is indicated pathologically by the inability of the tissues to form protective adhesions.

In cases of general peritonitis, appendicectomy certainly appears to be the rational treatment rather than temporising with a perforated or gangrenous appendix which provides a constant stream of infection. However, there are two points which merit brief reference.

1. If operation is performed the appendix should always be removed if reasonably possible, but with a minimum of exposure and manipulation. Any unnecessary manipulation increases lymphatic and venous absorption of toxins. The old-fashioned procedure of evisceration and scrupulous peritoneal cleansing produced acute toxæmia which was emphasised by the term "post-operative shock," but in reality was a massive and lethal dose of toxæmia.

2. If the general condition of the patient is precarious so that the operative risk is obviously high, then expectant treatment should be given a trial, and it is surprising how some hopeless cases respond and either resolve or else form a localised abscess. In profoundly toxic cases the administration of glucose in rectal saline is a valuable adjunct to treatment, and if an anæsthetic is administered chloroform should be regarded as a poison owing to its deleterious effect on the liver cells, which are already seriously impaired by toxæmia. I have collected 12 cases in which jejunostomy was performed almost as a last resort in cases of peritonitic ileus. There were nine deaths and three recoveries. This may not seem very encouraging, but it must be remembered that the three recoveries were three pleasant surprises. These patients are desiccated by vomiting and may be unable to retain fluid in the form of enemata; jejunostomy is therefore valuable in that it allows administration of adequate quantities of saline and glucose, with consequent dilution of toxins in the body fluids. Antigangrene serum appears to be of some value in these cases, but choline is disappointing.

3. The third group demands critical consideration, and comprises those cases in which inflammation is limited to the right iliac fossa, and which present themselves from the second day of the disease onwards as a localised peritonitis or a circumscribed abscess. In both cases three quadrants of the abdomen are relatively free from tenderness or rigidity, and if localised peritonitis is present rigidity is marked in the lower right quadrant, and an indefinite and tender mass may be palpated. If suppuration ensues the rigidity becomes less marked and the swelling more

defined. When localised peritonitis is present appendicectomy may be extremely difficult, and I have on more than one occasion witnessed an attempt at appendicectomy abandoned after prolonged searching and considerable trauma to tissues. The congestion and turgidity of the bowel and omentum, the friability of the tissues, and the presence of adhesions are all stumbling-blocks to a well-executed operation. Moreover, however gentle interference may be, or however carefully packing is inserted, the early protective adhesions are easily separated, and general peritonitis may result when originally only a local infection was present. During my military service I twice assisted a surgeon in India to literally tear out two appendices which were firmly matted and behind a turgid cæcum. Both cases ended fatally, and in the light of subsequent observation I believe that these cases would have subsided, or rather were actually subsiding, at the time of operation. If a localised abscess is present, attempts at appendicectomy, as far as the local condition is concerned, may be even more dangerous. Besides the risk of contamination by pus there is the difficulty of knowing when to cease searching for, or endeavouring to separate, an unwilling appendix, and this problem may tax the judgment of the most experienced.

Technique of Delayed Treatment.

It will perhaps be expedient to epitomise the routine adopted when delayed treatment is employed. If infection has spread beyond the confines of the appendix, the patient is placed in Fowler's position, fomentations are applied locally to relieve pain, and only water is allowed by the mouth until the patient expresses a desire for nourishment, which usually coincides with the fall of temperature. A four-hourly chart is kept, so that temporary variations of pulse and temperature are recorded. No aperient is given, if flatulence or distension cause discomfort, then a small soap and water or glycerine enema is administered. Sudden distension of the rectum by a large enema should be avoided, as an abscess has been ruptured by this means. If the signs and symptoms abate, then the patient should be kept in bed for a week after the temperature and pulse have been normal, or until the lump has disappeared. In the minority of cases the surgeon's hand may be forced and intervention may be necessary in delayed cases for the following reasons :—

1. Persistence of rapidity of pulse or elevation of temperature, particularly when considered in conjunction with local signs.
2. The formation of an abscess which increases in size, owing to the risk of rupture into the general peritoneal cavity. Gas and oxygen anæsthesia is usually sufficient for these cases.
3. Slow absorption of an abscess, in which case degeneration of viscera may occur.

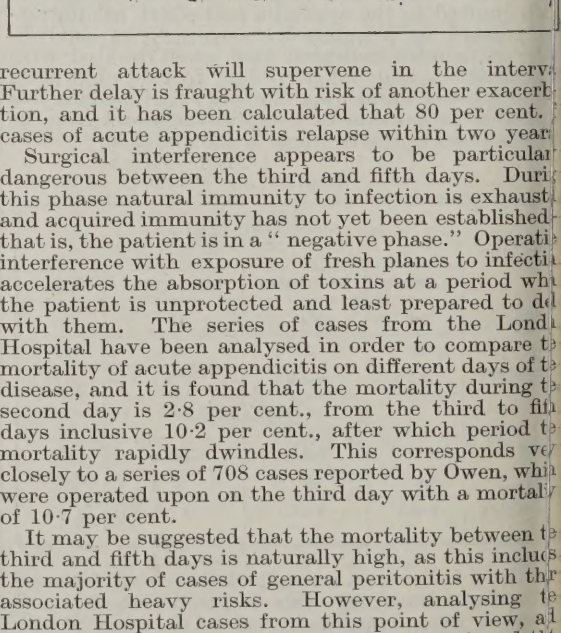
A case has been referred to in one paper on this subject in which delayed treatment was successfully adopted in a healthy man, but after subsequent appendicectomy fatal heart failure supervened. At post-mortem examination the heart muscle was found to be degenerated and fatty, and this was presumed to be due to toxæmia following the absorption of the abscess.

It must be clearly and emphatically stated that delayed treatment can only be adopted when the patient is under continuous supervision and complete control—that is, usually in a hospital or nursing home—and the routine treatment already indicated must be adhered to rigidly. Delayed treatment is generally unsuitable in patients whose resistance is at a low ebb—e.g., at the two extremes of life, or following severe illness or pregnancy. Acute appendicitis carries a mortality of about 13 per cent. in children during the first decade, and these cases are unlikely to subside, partly as a result of the energetic exhibition of purgatives. As Adams dramatically states[4]: "The mother may be an unconscious murderer of her own child, and a dose of castor oil may be as poisonous as a dose of hemlock." Recently an account appeared in THE LANCET of 50 cases analysed from Addenbrooke's Hospital [5] in order to gauge the effect of castor o when administered to children with acute appendicitis and it was found that the appendices in eight cases i which oil had been given were all gangrenous, whereas in 42 cases which had been spared the oil only two were gangrenous. It should be realised that gangren is not entirely due to the stimulating and irritatin effect of the purgative, but also to delay whil awaiting the result of the administration. Further more, the age and intelligence of children naturall handicap them in expressing their symptoms, an thus symptoms may be missed in the early stages c errors may be made in diagnosis.

The Time for Surgical Intervention.

If delayed treatment is successful then the questio arises as to the best time for appendicectomy. It surprising how long is needed for the last dregs pus to be absorbed, and, although pus is relativel innocuous after resistance has been established, appears wise to wait until all traces of acute infectio have subsided. Probably the best plan to adopt is f the patient to leave hospital and return three montl after for a clean appendicectomy. This affords amp time for visceral regeneration, presuming son degeneration had occurred, and it is unlikely that

FIG. 1.



recurrent attack will supervene in the interv Further delay is fraught with risk of another exacerb tion, and it has been calculated that 80 per cent. cases of acute appendicitis relapse within two year

Surgical interference appears to be particula dangerous between the third and fifth days. Duri this phase natural immunity to infection is exhaust and acquired immunity has not yet been established that is, the patient is in a "negative phase." Operati interference with exposure of fresh planes to infecti accelerates the absorption of toxins at a period wh the patient is unprotected and least prepared to d with them. The series of cases from the Lond Hospital have been analysed in order to compare t mortality of acute appendicitis on different days of t disease, and it is found that the mortality during t second day is 2·8 per cent., from the third to fi days inclusive 10·2 per cent., after which period t mortality rapidly dwindles. This corresponds ve closely to a series of 708 cases reported by Owen, wh were operated upon on the third day with a mortal of 10·7 per cent.

It may be suggested that the mortality between t third and fifth days is naturally high, as this inclu the majority of cases of general peritonitis with th associated heavy risks. However, analysing t London Hospital cases from this point of view, a excluding cases of general peritonitis, it is found t 401 cases were operated upon between third and fi

ys with either local peritonitis or local abscess, and ended fatally—that is, the operative risk, when ection was localised to the right iliac fossa, was per cent.

In an endeavour to find some pathological support the high mortality during this dangerous period, have compiled a series of leucocyte counts on ferent days of the disease. The accompanying art (Fig. 1) indicates the average total number of icocytes present in the blood in a series of 29 patients, of whom presented an inflammatory mass in the ht iliac fossa, and who responded to delayed atment.

From this it will be seen that there is no marked e in the total number of leucocytes until after the h day. An even more significant fact is that there no marked increased proportion of polymorpho-clear cells until after the sixth day. This is mittedly a small series of cases, but presuming that eucocytosis bears some relation to the resistance to ection, then the chart supports the contention that e third to the fifth days may be regarded as the ngerous period.

Criticisms of Delayed Treatment.

It may now be advisable to consider some of the ticisms levelled against delayed treatment. Four in objections have been advanced which may be mmarised as follows: the refusal of the patient to ow subsequent appendicectomy; the influence on blic opinion; expediency; and surgical reputation. In considering these objections in further detail, erence has already been made to the necessity of moving the appendix about three months after lammation has subsided. In some cases it may be ficult to persuade an obstinate patient to return operation, or he may delude himself in the hope at he will be fortunate enough to escape recurrence. is difficulty is overcome if the proper relationship ists between patient and surgeon—that is, one of plicit confidence. The main planks of the surgeon's gument are not only the risk of recurrent appendi-is, but the possibility of subsequent associated ease of other organs, and that interval appendicec-my has a negligible mortality and a limited and own period is required for convalescence.

It has been stated that "If the public recognise at immediate operation yields the best results in pendicitis, the doctor's duty will be simplified. If change this point of view the public will get the ea that appendicitis should be treated on medical d not on surgical lines." This objection suggests at the diagnosis of appendicitis is made by the blic, but even if such a state of affairs existed the ctor would probably be consulted in order to nfirm or disprove the diagnosis. Now the doctor's ty is clearly defined. Any case of acute appendicitis whatever stage is in urgent need of surgical treat-nt, either by operation or supervision, and public inion will reflect this standpoint whichever line of atment is subsequently adopted. It appears an olerable position that surgeons should allow public norance or prejudice to influence them in pursuing y line of treatment.

Delayed treatment certainly imposes a considerable x upon the time and skill of the surgeon, as frequent sits and examinations are necessary in order to note ogression or retrogression of infection. Further-ore, considerable judgment is necessary in order to cide when interference should be adopted if such necessary. However, it will be agreed that time and ouble are of no consequence if repaid by diminished ortality lists. If, of course, for geographical or her reasons the surgeon cannot maintain constant ntact with the patient, then, unless a firm small ass is present, appendicectomy is probably a wise urse. On the other hand, delayed treatment may the safest line to adopt in *any* stage of appendicitis, en at the onset, if surgical conveniences and ameni-s are not available.

Recently an appendix was removed on a small passenger at in the South Atlantic. The operation was performed during rough weather by an unassisted and recently qualified ship's doctor, using spoons as retractors, with the purser acting in the rôle of anæsthetist. The passenger survived and was carried ashore at Plymouth with a suppurating wound, and the ship's doctor received grateful thanks from the patient and congratulations from the ship's company. In reality, the risk to which the patient was exposed by operation under prevailing conditions must have been very considerably greater than if he had been starved in Fowler's position.

When inflammation has spread beyond the appendix, whatever treatment is adopted, a small but definite mortality must be expected. If a case treated on delayed lines ends fatally, it is usually regarded as a tragedy, and all concerned may have lingering doubts in their minds as to whether immediate operation would not have saved the patient. On the other hand, if the appendix is immediately removed and the patient succumbs, the general impression is that, because active treatment was adopted, everything possible was done and the fatality is accepted philosophically. The point I wish to stress is that a masterly inactivity demands a high standard of courage on the part of the surgeon and the implicit confidence of the patient.

If delayed treatment is successful, not only is the actual mortality of acute appendicitis diminished, but post-operative complications are reduced to about one-third of the number which follow immediate operation. Immediate complications—e.g., fæcal fistula and secondary abscesses—are favoured by the necessity for drainage and separation of adhesions, whilst sequelæ, such as adhesions and incisional herniæ, are to be expected after drainage of the peritoneal cavity and infection of the parietes.

I would here make a suggestion regarding the method of drainage when such is necessary in acute cases. If a gridiron incision has been made and pelvic drainage is needed, this should always be obtained by a separate suprapubic incision. In analysing the series of cases from the London Hospital complications, fatal and incidental, were more than twice as common when the pelvis was drained through the gridiron incision than by more direct suprapubic drainage. This is accounted for by the shorter and more dependent suprapubic route, and the absence of pressure by the tube on the inflamed cæcum which predisposes to fæcal fistula.

I note with considerable relief that most recent papers on this subject now at least consider the merits of delayed treatment, and I heartily endorse the conclusions of Rayner based on observations at the Manchester Royal Infirmary,[3] which I quote herewith, as they approximate to my own views. He states: "I think we may, from our clinical experience and observation at operation, recognise certain types in which it is safer, and in other ways better for the patient, that immediate operation should not be undertaken, such for example are the following:—

1. The patient who presents a firm, hard mass in the right iliac fossa, right loin, or over the forepart of the iliac crest; the mass is ill-defined at its edges, often extensive, and free from marked tenderness. Such a case will commonly subside entirely, or the mass slowly resolve into a well shut-off abscess, which can be easily and safely opened. Immediate operation is difficult and unsatisfactory, and convalescence prolonged and troublesome.

2. The patient who presents an area of well-localised muscular rigidity without extreme tenderness over the appendicular site. His temperature is raised and the pulse moderately accelerated. Such a patient is by no means best dealt with by immediate operation, and the following circumstances should be regarded as indicating a temporising policy: (*a*) retrocæcal position; (*b*) general condition unfavourable by reason of stoutness, bronchitis, emphysema, alcoholic tendency; (*c*) history of preceding attacks which have subsided; (*d*) unfavourable environment.

Subsequently he adds: "I believe it is possible to exercise discrimination in some cases without adding to the risk of others."

Sherren,[6] after over 20 years' experience at the London Hospital, states: "The only change I have

made has been to greater conservatism and more patience in dealing with cases of appendix abscess."

Conclusions.

These statistics, observations, and opinions all constitute a very earnest plea for discrimination in dealing with cases where infection has begun to localise, and has already localised in the right iliac fossa. The 9 per cent. mortality, which is the price paid for immediate interference in these localised or localising cases during the third and fifth days, is tragically high when one considers that nature has successfully erected a barrier to infection and that immunity is increasing daily.

When the pathology of acute appendicitis was first appreciated the pendulum of treatment swung from purely medical, under the care of a physician, to immediate operation by the surgeon, and normal beneficent reaction of tissues to inflammation was regarded with suspicion. In discriminating hands the pendulum in coming to rest in an intermediate position, and I anticipate the day when the rule-of-thumb surgeon, who operates on every case as soon as he sees it, will be as out of date as the physician who, in years gone by, treated perityphilitis by purgatives and enemata.

II.—Acute Cholecystitis.

The problems concerning the treatment of acute cholecystitis resemble to some extent those which have been discussed in connexion with acute appendicitis, and it is apparent that surgeons still differ as to whether cases of acute cholecystitis should be submitted to immediate operation, or whether opportunity should be given for remission. On the one hand, a well-known surgeon states that "Cholecystectomy during the acute stage is an unwarrantable danger," and on the other hand a surgeon of international repute recommends immediate operation, cholecystectomy being the objective.

In reviewing Continental and American literature one finds that the treatment tends towards expectancy—that is, of allowing acute inflammation the opportunity to subside with subsequent operation after remission of symptoms. Hotz, in a paper presented to the German Surgical Association in 1923, produced figures which indicated that the mortality of operation during an acute attack was double of that which followed operation after remission. Following a discussion at the Surgical Society at Lyons in 1923 the French schools were doubtful of the wisdom of immediate operation and were of the opinion that if operation was indicated during an acute attack of cholecystitis, then drainage of the gall-bladder was preferable to removal, and in 1926 these views were confirmed by Pauchet. Last year Bruggeman [7] read a paper before the Western Surgical Association of the United States and produced statistics supporting expectant treatment.

In comparing the pathology of acute cholecystitis with that of acute appendicitis, it is found that generalised infection of the peritoneum is a much less common complication in cases of inflammation of the gall-bladder. The gall-bladder is rapidly shut off by adhesions between the liver, transverse colon, mesocolon, and omentum, so that perforation of the gall-bladder into the general peritoneal cavity is an uncommon event. In acute cases it is easy to imagine at operation that the gall-bladder is on the point of bursting, and that the operation has fortunately just averted this calamity. Turgidity may be confused with distension, and in acute cases the wall of the œdematous gall-bladder may measure half an inch or more in thickness. Popular opinion pictures the gall-bladder bursting like an overblown balloon, but perforation is probably in all cases due to local gangrene of the wall of the gall-bladder.

I have reviewed 107 cases of acute cholecystitis, the majority of whom were admitted to the London Hospital during the period 1922–26, and have divided them into those treated expectantly and those operated upon immediately (Table II). On examining these figures we find a mortality of 20 per cent associated with immediate operation. This is due in some measure to similar causes to those mentioned in connexion with acute appendicitis—that is, transitory lack of resistance of the patient and increased infec

tivity of gall-bladder contents during the exacerbatio and the greater difficulty of an operation conducte on acutely inflamed viscera.

As compared with acute appendicitis, however, a additional factor manifests itself in the shape of lu complications. Out of eight cases which died followi immediate operation, no less than three deaths we attributed to pneumonia. The association of acu cholecystitis and pneumonia has been emphasised b Wilkie,[8] and no doubt the anæsthetic and limitatio of movement of the diaphragm following operati trauma precipitates pneumonia in these cases.

If cases are treated expectantly the routine adopte is similar to that already described for acute append citis, with the addition that a dose of morphia advisable when it has been definitely decided postpone immediate operation. The mortality of a cases treated expectantly was 13 per cent., and inte vention was necessary in nine cases out of 52 whi were treated on expectant lines. In two of these cas general peritonitis was present following gangrene the gall-bladder. In four of the remainder a localis abscess formed around the gall-bladder; in one ca stones were found in the pus, indicating perforatio The remaining three cases did not subside, althou infection was still limited to the gall-bladder. Cho cystectomy was performed in the majority of cas which subsided, obesity and shrunken adherent ga bladders preventing removal in only five out of 43 cas Four deaths occurred, two of them being due pulmonary embolism, both on the sixth day aft operation. One of these cases was operated up when the temperature had barely settled and t pathologist reported that the gall-bladder show "acute hæmorrhagic and focal necrosis." This sugge that operation was somewhat premature and that t return of temperature to normal does not coincide wi subsidence of inflammation. Probably a suitable ti for operation would be one week after the disappe ance of all signs and symptoms. Of the other t deaths which occurred in cases which had subsid one was due to subphrenic abscess and the oth apparently to lung complications.

Not only is the mortality lower in cases treat expectantly, but in a much greater proportion patients the satisfactory operation of cholecyst tomy may be performed rather than mere cho cystostomy. Of 38 cases operated upon immediat the gall-bladder was removed in 22—that 58 per cent.—whereas of 52 cases treated exp tantly, cholecystectomy was performed in 41, 79 per cent.

There are two main objections to be levelled at delayed treatment:—

1. The patient may refuse subsequent operation. In this series, out of 69 cases which successfully subsided, in 17 no subsequent operation was performed. Some of these cases were unsuitable for surgical treatment, most commonly on the grounds of obesity, and so no operation was urged, but in at least five cases operation was definitely refused. It appears to be a human characteristic that as the sands of time run low, to regard them as increasingly precious, and the older the patient the less willing are they to submit to what they consider "the risk of an operation."

2. The second objection is the greater possibility of an erroneous diagnosis as compared with acute appendicitis. Perforated ulcers, intestinal obstruction, acute pancreatitis, and inflammation of a high appendix may all be mistaken for acute cholecystitis. Right basal pneumonia with reflex rigidity of the upper part of the right rectus is another possible error, and, as already mentioned, the two conditions may be associated.

These two objections to expectant treatment are countered by laying facts plainly before the patient and explaining that interval operation is the lesser of the two risks, and the risk of erroneous diagnosis is reduced by careful clinical examination. Of course, if a reasonable element of doubt exists regarding diagnosis, then the expectant treatment is not recommended; also in this condition, as with appendicitis, expectant treatment can only satisfactorily be adopted when the patient is under supervision and control.

A dissertation on the differential diagnosis of acute cholecystitis would be wearisome, but there is one physicial sign which is frequently present and very reassuring when elicited. This sign, associated with the name of Boas, consists of hyperæsthesia of the seventh, eighth, and ninth thoracic segments. It is best detected below the angle of the right scapula, and depends upon distension of the gall-bladder with consequent stretching of the visceral peritoneum. In cases of a distended high appendix hyperæsthesia will be located in the usual appendicular triangle—that is, an area the apex of which is at the umbilicus and the base along the outer half of Poupart's ligament—and the location of hyperæsthesia may be a valuable and convincing sign in distinguishing acute inflammation of the gall-bladder and appendix.

From these statistics one is enabled to draw the following conclusions: 1. Operation during an acute attack of cholecystitis carries a high mortality. In this series of cases 21 per cent. 2. Most cases treated expectantly will subside. In this series out of 69 cases treated expectantly, in only nine cases was intervention necessary. 3. If expectant treatment is successful, then in a much larger proportion of cases the complete and desirable operation of cholecystectomy is possible.

Hence the review of these cases support the contention that expectant treatment carries a lower mortality and allows of safer and more efficient surgical treatment, as compared with immediate operation.

III.—Acute Pancreatitis.

The incidence of acute pancreatitis is about one case in every 5000 surgical emergencies.[9] It is a prevalent opinion that acute pancreatitis is commoner in the male sex, but most recent papers on the subject fail to support this contention. I have collected 51 cases admitted to the London Hospital between 1911 and 1924,[10] and of these 31, or 68 per cent., occurred in females. With regard to the predisposing influence of age, the commonest decade is the fifth, but the age-incidence varies within wide limits, and in this series the youngest was a girl of 11 and the oldest a female of 73.

Until recent years the diagnosis of this condition was unusual before the abdomen was explored on the operating table. More careful attention to clinical features now results in accurate diagnosis in the majority of cases. The sudden onset, continuous vomiting, and cyanosis are all suggestive. As with perforation of an ulcer, marked prostration is also present, and as Moynihan points out, "shock" is an incorrect term to apply to this condition, as it is not associated with marked diminution of the blood pressure. Abdominal rigidity varies inversely to the degree of prostration, and therefore is absent for a variable time after the onset of infection—i.e., during which period the prostration is still profound.

Special tests have naturally little scope for application in emergency surgery, but the adrenalin mydriasis test of Loewi may be of value in establishing a diagnosis. Positive results were obtained by Waring and Griffiths in three out of four cases, and by Hamilton Bailey in four cases out of five. The diastase index of the urine is of no significance, as it may be increased in other acute abdominal conditions—e.g., pneumococcal peritonitis. The previous history of many cases of acute pancreatitis is of interest in that it indicates that the condition may be progressive, and that less severe attacks sometimes precede the final catastrophe. Excluding as carefully as possible attacks of abdominal pain due to other causes, in this series of 51 cases no less than 31 gave a history of previous similar attacks and five were inconclusive, leaving a residue of 15 patients whose first attack needed surgical intervention.

A striking example of a successive attack was a case in which laparotomy was performed for abdominal pain of obscure origin. A condition of "chronic pancreatitis" was diagnosed and the abdomen closed. One month later the patient was hurriedly returned from convalescent home with an attack of acute hæmorrhagic pancreatitis, which was confirmed at post mortem. An even more illuminating instance of the recurrence of the condition with increasing severity may be quoted in more detail:—

Case of A. B., brewer's drayman.

1907: Aged 36. Was suddenly seized with acute abdominal pain. The diagnosis of "acute alcoholic gastritis" was made, and the patient attended the medical out-patient department. He was discharged a few weeks later as cured.

1910: Drank a glass of cold water and was suddenly seized with severe pain, similar to previous attack, vomited several times, and was admitted to hospital. On examination some tenderness and rigidity was present over the gall-bladder area. The symptoms abated and he was discharged.

February, 1924: Third severe attack while rolling barrels. Pain so acute that patient became unconscious. On admission to hospital prostration was well marked, cyanosis was present, and rigidity was entirely absent. A diagnosis of acute pancreatitis was made, and the abdomen opened through a right paramedial incision. Fat necrosis was general, the pancreas was swollen and œdematous, and the gall-bladder was distended, but no stones were present. Cholecystostomy was performed and the patient recovered.

July, 1924: The patient was seized with a fourth attack similar to those described above. He was admitted moribund and died shortly afterwards.

Causation.

The causation of acute pancreatitis is still obscure. The two theories most commonly held are either infection by lymphatic spread, or regurgitation of infected bile along the pancreatic duct. Experimental work, such as the injection of organisms into the neighbouring lymphatic glands, has failed to support the theory of lymphatic spread, although this route is still suggested in cases in which the biliary passages are healthy. Regurgitation of infected bile is almost self-evident in cases in which the ampulla of Vater is obstructed by an impacted gall-stone, and acute pancreatitis has also been associated with sarcoma of the ampulla, and, as in a case reported by Sir Hugh Rigby,[11] followed blockage of the duct by a round-worm. Even in cases in which no gall-stone or other obstruction is present, the regurgitation theory may still be accepted on the assumption that reflex spasm of the sphincteric muscle of Oddi diverts the flow of bile along the pancreatic duct, the stimulus precipitating the reflex being some other pathological condition or derangement within the abdomen.

Among the post-mortem records of the London Hospital there are reports of two cases of death due to strangulation, both of whom showed fat necrosis in the region of the pancreas. This association suggests that venous stasis may possibly predispose to acute pancreatitis. Over 50 per cent. of cases of acute pancreatitis are associated with cholecystitis or gall-stones, and many of the remainder with some other abdominal focus of infection. As a free communication exists between abdominal lymphatics, adenitis of the subpyloric glands in the head of the pancreas may result from abdominal infection, particularly biliary. It is possible that enlargement of these glands obstructs the venous return from the pancreas. Again, acute pancreatitis is relatively more common in those of alcoholic tendency, and the resulting gastritis may be an additional cause of adenitis of the pancreatic glands. Furthermore, obesity definitely predisposes to acute infection of the pancreas, and excessive fat encourages generalised venous stasis.

Surgical Treatment.

With regard to the surgical treatment of acute pancreatitis three operative measures are commonly adopted. These are: 1. Local drainage of the pancreatic area. 2. Drainage of the gall-bladder or biliary passages. 3. Incision and drainage of the pancreas itself.

I have collected from hospital records and published statistics 52 cases in which one of these three procedures has been adopted, excluding those cases in which a combination of measures was deemed necessary. Out of 18 in which local drainage only was adopted five died—that is, a mortality of 28 per cent. In 28 cases drainage of the gall-bladder or common bile-duct was performed with 11 deaths—that is, a mortality of 39 per cent. In all these cases either gall-stones or previous infection of the gall-bladder was present. These figures suggest that the prognosis is worse if pathological conditions of the biliary passages coexist.

In six cases the pancreas itself was incised and drained; five of these terminated fatally—that is, a mortality of 83 per cent. These are scanty figures, and possibly in these cases infection may have been more advanced or extensive, so that incision of the gland was considered necessary. However, incision, or even stabbing the gland with blunt forceps appears to be inadvisable for the following reasons:—

1. Incision causes local hæmorrhage and superimposes trauma on infection.

2. Non-infected areas are exposed to infection and incision encourages the spread of infection to healthy parts of the gland.

3. The pancreatico-duodenal arteries may be injured, and cases of duodenal fistulæ have occurred after incision of the gland.

These figures suggest that in all cases of acute pancreatitis it is wise to incise the peritoneum carefully over the pancreas so as to avoid injury to the gland. If the gall-bladder contains stones, is fat-laden, or its colour other than the normal slate-blue, then cholecystostomy should be performed in addition to drainage of the pancreatic area. Mere distension of the gall-bladder should be ignored, as one would expect œdema of the head of the pancreas to cause some degree of obstruction to the common bile-duct. Archibald [12] has suggested that the sphincter of Oddi might be divided transduodenally in order to overcome spasm and relieve possible tension in the pancreatic ducts.

It has been shown experimentally that relaxation of the sphincter is produced by painting the duodenal mucosa with a weak solution of magnesium sulphate (which possibly explains the beneficial effect attributed to the early morning dose of salts). However, it would seem more practical to inject with a syringe and fine needle a few cubic centimetres of a 5 per cent. solution of magnesium sulphate into the first part of the duodenum. This manœuvre would be free from danger and occupy but a moment. Presuming that spasm of the sphincter is in certain cases the actual, or even a contributing cause of acute pancreatitis, and that the physiological relaxation of the sphincter is obtained under pathological conditions, then intra-duodenal injection of magnesium sulphate should produce a beneficial effect.

With regard to drainage of the pancreatic area the drainage-tube should be wide in calibre, as surprisingly large sloughs may separate and these need a roomy exit. In cases which survive the first week some anxiety may arise during the ensuing days on account of this sloughing of masses of pancreatic tissue which may be associated with some degree of secondary hæmorrhage, in addition to the difficulty of their discharge along the path provided.

The tube itself should emerge through a separate stab wound rather than through the laparotomy incision, as pancreatic enzymes, activated by mild infection, may cause early disintegration of catgut or weakening of the scar with consequent breaking down of the wound, which may need secondary suture, or later cause an incision hernia. Posterior drainage of the pancreas may be obtained either by an incision below the twelfth rib on the left side, or after resection of part of the tenth left rib. This route is unlikely to be practicable in cases of acute infection as, if adopted as a primary measure in diagnosed cases, the surgeon remains in ignorance regarding the condition of the gall-bladder, and only limited drainage can be obtained in the region of the tail of the pancreas. If the abdomen is already opened from the front then the acquisition of posterior drainage necessitates further incisions, and change of posture in a patient whose condition already causes anxiety. In cases of pancreatic cyst the advisability of posterior drainage should certainly be considered.

With regard to after-treatment, reference has already been made to the digestive properties of the fluid discharged, and excoriation of the surrounding skin should be prevented by some mineral fat, if necessary containing a weak acid in order to prevent activation of the enzyme.

Owing to the pancreatic deficiency which naturally follows destruction and infection of at least a portion of the gland, pancreatised food or some pancreatic preparation must be given in order to maintain adequate nutrition of the patient. In this connexion it will be recalled that persistent abdominal discomfort and dyspepsia is sometimes a troublesome sequela after cholecystectomy for gall-stones. Many of these cases are relieved by pancreatic preparations, owing to the association of chronic pancreatitis and pancreatic deficiency with infection of the biliary passages.

Glycosuria is an occasional sequela to acute pancreatitis, and in one case the urine contained 2·5 per cent. of sugar, one month after operation. Possibly chronic pancreatitis had previously affected the islands of Langerhans. The possibility of glycosuria should be borne in mind so that a suitable medical régime may be instituted if necessary. Reference has already been made to the contention that mild attacks of acute pancreatitis commonly precede a surgical catastrophe, and the corollary is also true; thus subsequent attacks may occur in a patient who has already been tided over an acute attack by a timely operation. In one case in this series a recurrent attack occurred while the patient was still in bed, 22 days after cholecystectomy had been performed for acute pancreatitis. The attack abated under the influence of morphia.

In reviewing the series of cases which form the basis of this paper, it appears that recurrent attacks are commoner in cases associated with gall-stones and cholecystitis. This suggests that when once pancreatic infection is established then an infected condition of the biliary passages predisposes to reinfection of the pancreas.

IV.—SPINAL ANÆSTHESIA.

Methods of anæsthesia other than induction via the respiratory passages are much less popular in this country than on the continent. In many French schools splanchnic anæsthesia is used almost as a routine for abdominal work. In this country spinal anæsthesia is most commonly used in cases in which

cardiac or pulmonary conditions constitute an additional risk to the administration of a general anæsthetic, and this method is commonly considered undesirable in cases of shock or diminished blood pressure, as owing to complete relaxation of the abdominal wall splanchnic stasis is encouraged.

Most of the instances in which fainting or collapse of the patient causes anxiety or alarm are readily preventable by posture. After a period of seven to ten minutes, during which the anæsthetic becomes fixed to the nerve elements, the table should always be tilted so that the head is lowered. In gynæcological operations under spinal anæsthesia conducted in the Trendelenburg position the condition of the patient seldom gives rise to concern. The effect of posture should always be borne in mind, not only during but also after the operation. I have seen sudden collapse of a patient on the stairs of a nursing home, down which she was being carried feet first. Lack of this simple precaution has caused calamities which tend to bring a valuable measure into disrepute. If considered advisable an additional precaution may be obtained by auto-infusion—that is, firmly bandaging the patient's limbs so as to limit the amount of blood in the systemic circulation.

A somewhat inexplicable and fortuitous advantage of spinal anæsthesia occasionally occurs in cases of paralytic ileus. On two occasions I have seen copious relaxation of the bowels occur on the operating table within a few minutes of injection, and other surgeons have experienced this happy result.

Cases of acute intussusception furnish an excellent instance of the advantages of spinal anæsthesia. It has been suggested that owing to the relatively longer spinal cord in infants that this structure is endangered. However, it will be recalled that even at birth the spinal cord only reaches to the upper border of the third lumbar vertebra, so that an injection at the usual site—that is, between third and fourth lumbar vertebræ—is obviously devoid of risk. In semi-shocked infants under general anæsthesia a narrow margin separates muscular rigidity from surgical relaxation, and a safe yet efficient degree of anæsthesia is difficult to maintain even with a skilled anæsthetist, and emergency surgery frequently precludes expert assistance. The operation for acute intussusception under indifferent anæsthesia results in excessive escape of bowel, ungentle manipulation and delay, and difficulty in suturing the parietes. It is still a tradition in some hospitals that in order to limit the risk of a "burst abdomen" the stitches in cases of acute intussusception are not removed until the twelfth day instead of the usual tenth day. If the child is incompletely anæsthetised the task of systematically approximating the peritoneum and parietes may be insurmountable, and recourse may, of necessity, be made to simple through-and-through suture. This crude procedure must obviously predispose to subsequent ventral hernia, and in addition cases of obstruction from adherent bowel have been reported.

Hamilton Bailey,[13] in an amplified personal communication, reports 16 cases of acute intussusception induced under spinal anæsthesia, with one death, and have personal notes of 23 cases treated on these lines with three deaths, in two of which the gut was gangrenous. In none of these 39 cases was difficulty experienced in suturing the abdominal wall, nor did subsequent healing give rise to apprehension. Furthermore, complete relaxation undoubtedly saved time and trauma in manipulation and suturing, and improved the prognosis in many cases.

With regard to the technique of administration of novaine in children, the usual dose for a child between six months and one year is 0·2 c.cm., which amount may be varied according to the weight of the child. The Barker's needles commonly used for spinal puncture are too large, and a shorter and finer needle should be substituted. The syringe must be plainly graduated so that the dose can be accurately measured. After injection the child may be placated by being allowed to suck a strip of gauze moistened with glycerine.

In conclusion, I would advocate the more general use of spinal anæsthesia in acute abdominal surgery, provided that the necessity of posture is constantly borne in mind. In acute intussusception in particular, the ease and gentleness of manipulation and speedy efficient closure of the abdomen undoubtedly diminishes both the immediate operative mortality and the risk of sequelæ and complications associated with imperfect suture of the abdominal wound.

Finally, I must express my indebtedness to various surgeons at the London Hospital for their ready permission to amass statistics from cases under their care and treatment.

INTRAVENOUS ANTITOXIN IN SCARLET FEVER.

BY H. STANLEY BANKS, M.B. GLASG., D.P.H.,
MEDICAL SUPERINTENDENT, CITY HOSPITAL AND SANATORIUM, LEICESTER;
AND
JOHN C. H. MACKENZIE, M.B. GLASG.,
SENIOR ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

OBSERVATIONS on the treatment of scarlet fever by the specific antitoxin have been made by a number of workers, both in America and in this country, during the past three or four years. Their reports are, however, chiefly based upon the results of subcutaneous or intramuscular injection of the serum, and the intravenous route has, we believe, been employed only in relatively few severe or toxic cases. The results obtained are concisely summed up in Sir George Newman's Annual Report for 1927. "Scarlet fever antitoxin is being increasingly used and has proved effective in the treatment of this disease. Although it appears to have no direct effect on the cure of complications, its early administration lessens the toxæmia, and cases so treated have shown less tendency to develop septic complications. Its use reduces the average stay in hospital and should assist in reducing the number of hospital admissions. A small dose, 2·5 c.cm. to 5 c.cm. of the concentrated serum, can be used to confer a temporary passive immunity of from one to two weeks' duration on the immediate contacts of the case." This general statement of the present position may be supplemented by reference to certain details dealt with by J. C. B. Craig[1] in a recent comprehensive paper on this subject. Craig describes the results obtained in Edinburgh by intramuscular injection of the serum in a series of 500 cases, mostly of a mild type, with controls. The following important practical points, amongst others, were brought out:—

1. Beyond the third day of the disease, antitoxin seems to have little effect in influencing the incidence of subsequent complications.

2. The incidence of otitis media in cases treated with serum during the first three days of the disease was 8·3 per cent.

3. It does not seem advisable to reduce the quarantine period to less than four weeks. Fresh complications developed after the fourth week of disease in 14 serum-treated patients.

From the figures quoted, it appears that the average stay in hospital of the serum-treated cases was

[1] THE LANCET, 1928, ii., 1123.

almost five weeks, and of the control cases, almost seven weeks.

Rather better results from intramuscular injection were obtained by E. H. R. Harries,[2] who reported a 2 per cent. incidence of otitis media in Birmingham in 100 serum-treated cases, as compared with 9 per cent. in the control series. Harries considered that, although many serum-treated cases appeared to be ready for discharge from hospital in three weeks from the onset, "at the present stage it seems inadvisable to discharge them earlier than 30 days from onset."

Results of Intravenous Injection.

The present communication deals with the results of intravenous injection of scarlatinal antitoxin in 404 cases of scarlet fever treated in the City of Leicester Isolation Hospital during the seven months May to December, 1928. Before this period we had commonly employed the serum intramuscularly with results somewhat similar to those referred to above. In the hope of obtaining better results we began to inject intravenously. It soon became evident that by this means the acute stage of the disease could be still more curtailed, complications prevented, and the stay in hospital still further materially reduced. A period of high epidemic prevalence of the disease occurred during the period of the experiment, and it became necessary to utilise existing hospital accommodation in the most economical way. We therefore came gradually to use intravenous injection as the routine method of treatment for all definite cases admitted in the acute stage, even up to the fifth or sixth day of disease. Certain exceptional cases were, however, recognised. Children under the age of two years were generally judged too young for intravenous injection. In cases with a history of asthma or other form of protein sensitiveness, or with definite bronchitis or acute respiratory disease, intravenous injection was held to be contra-indicated on account of protein shock. In some other cases difficulty was encountered with a vein. To all falling into those categories intramuscular serum was given. Doubtful cases were given 3 or 4 c.cm. intramuscularly, either for prophylaxis or treatment. Cases admitted late in the disease, and some very mild cases, were treated without serum.

The actual allocation of all cases amongst these groups during the period May to December, 1928, was :—

Cases treated with antitoxin intravenously ..	404
,, ,, ,, ,, intramuscularly ..	68
,, ,, ,, ,, ,, as prophylactic	20
,, ,, without antitoxin	240
Total cases discharged during the period ..	732

The proportion of serum-treated cases rose steeply during the later months as experience developed.

The effect of intravenous injection on the acute stage was almost invariably dramatic, even up to the fifth day of the disease. In a few cases (16) it was given on the sixth day with good results. When the patients were seen the next morning they were generally reading a book unconcernedly. The temperature had fallen below the normal line, the rash had faded, and œdema of the throat had subsided; there was no complaint of sore-throat, and they said they felt "much better." Practically the only patients who failed to respond quickly were those in whom dosage was considerably below the standard finally adopted.

We experimented during November with doses of about half the standard amounts. We found that cases receiving these smaller doses did quite well; they had very few and minor complications, and their average period of residence exceeded that of the October cases only by two days—i.e., 17½ days—but they did not have quite the same dramatic cessation of the acute stage as was associated with the full effective dose. The following chart (Fig. 1), selected at random, is quite typical of the great bulk of our cases.

As experience grew, we gradually shortened the average period of residence in hospital of the intravenous cases to about 15 days. Some were ever discharged after 9 or 10 days.

FIG. 1.

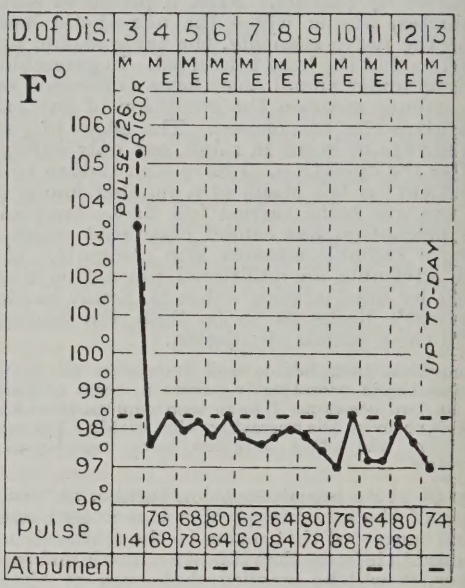

Chart showing effect of intravenous antitoxin in scarlet fever.

We soon observed that the complication-rate in intravenous cases was practically negligible, being limited to a very few minor septic manifestations. In actual fact, there was not a single instance of the more serious complications—viz., acute otitis media, nephritis, and arthritis. In order to be certain that complications were not occurring after discharge we made arrangements for all serum-treated cases to attend at the health offices for medical examination two or three weeks after discharge. The examination included a urine test for albumin. Out of 368 cases who were asked to attend, 334 actually appeared. The relevant defects noted were few and unimportant—viz., two cases of mild secondary tonsillitis and five with minor skin sepsis. No nephritis, albuminuria, or otitis occurred. Almost without exception these patients turned up cheerfully to report that all was well. We soon realised that the morbidity associated with scarlet fever was being materially reduced, permanent damage altogether prevented, and the loss of hundreds of weeks of school time for children and of business time for adults was being obviated.

From the administrative point of view the result of the experiment was no less gratifying. In the year 1928 there were 1972 notifications of scarlet fever in Leicester, the highest number recorded for 22 years. Had it not been for the new method of treatment it would have been impossible to accommodate all the cases that required hospital treatment without, at least, gravely interfering with other departments of hospital activity. As a matter of fact, the usual ward accommodation allotted to scarlet fever was not increased at any time, and we were able to hospitalise in this ward space about three times the number of cases usually dealt with. That infectivity was apparently not increased is shown by the fact that the number of "return" cases—i.e., cases appearing in a home within two months of the return home of a patient from hospital—was 12 for the period, or 1·6 per cent., which is rather below the usual figure of about 2 per cent.

[2] Medical Officer, 1927, xxxviii., 153.

The one unfavourable circumstance was a death, tributable mainly to protein shock after intra-nous injection of serum. This occurred in a weakly ild who was suffering from acute bronchitis. The se is described below.

Fig. 2 sets out the salient points relative to the vestigation.

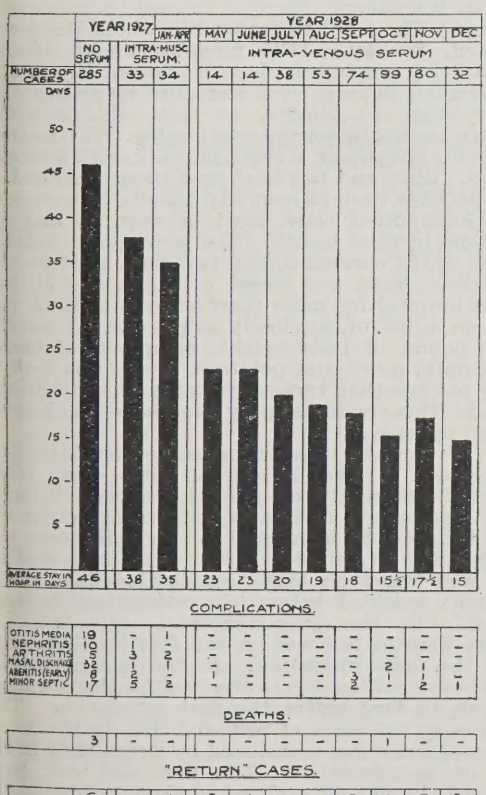
Special Features.

Certain additional points of interest were noted in e series of 404 intravenous cases.

Type of Scarlet Fever.—The prevailing type was ild. There were, however, a fair number of sharp ses, particularly among adults. Only seven cases ere definitely noted as being septic, and even in ese the sepsis subsided after a few days. Probably good many more would have become septic had the ute stage not been so dramatically arrested by travenous antitoxin.

Administration and Dosage of Serum.—Three different akes of serum were employed for intravenous jection in the early stages, and as the best results peared to be obtained with Parke, Davis and Co.'s ncentrated serum, this was used exclusively after e first 20 cases. Generally the effective dose was und to be about 20 c.cm. intravenously for an adult for a severe septic or toxic case, and 10 c.cm. for child or a moderate case. Rather smaller doses an these were given for milder cases. When several ses in a ward are being injected at the same time, e serum, which is issued in 10 c.cm. phials, can be ed economically by giving the fractions of a phial itable for each case—e.g., 5 to 7 c.cm. to a fairly ld case in a child, 10 c.cm. to a severer case in a ild, 13 c.cm. to a fairly mild case in an adult, and

FIG. 2.



t showing effect of intramuscular and intravenous antitoxin duration of residence in hospital, and on complications, aths, and "return" cases. During the period January to ril, 1928, there was one death—a septic case which was not ated with serum. Only cases treated intravenously have en shown for the period May to December, 1928; these stituted the great bulk of the cases.

20 c.cm. to a severe case in an adult. The warmed serum was slowly introduced undiluted into the median basilic vein by means of a 10 c.cm. or 20 c.cm. record syringe with peripheral nozzle. Before injecting the serum a few drops of blood were withdrawn

FIG. 3.

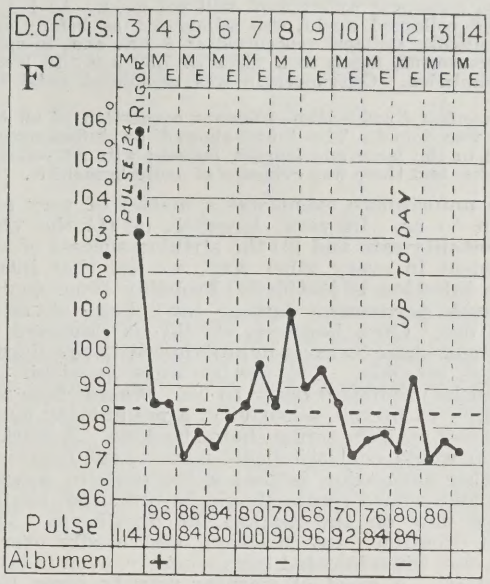


Chart showing secondary pyrexia following intravenous antitoxin in scarlet fever.

into the syringe. In work of this kind it is essential to have a good supply of short sharp, rigid needles of suitable bore and with fairly short points. A good light over the arm is another essential, and it makes for rapid working if there are a number of record syringes available, and a staff trained to wash out and boil the used syringes between injections. When the requisite organisation has been attained in a ward, it is not difficult to do seven or eight intravenous injections in an hour. Sometimes there was difficulty with a vein in a young or fractious child, and in such cases little time was wasted and the serum was injected intramuscularly.

Immediate Serum Reaction.—The intravenous injection is followed in fully 60 per cent. of the cases by a rigor and rise of temperature (which may be as high as 107° F.) within three-quarters of an hour. The colour is not infrequently poor and the pulse rapid. This reaction passes off within about half an hour, and the patient then generally falls asleep. Accordingly, in all cases, as soon as the injection was given, the foot of the bed was raised and the patient was surrounded with hot bottles and blankets until the rigor had passed off. Subcutaneous injection of adrenalin ℥iii. to ℥viii. prophylactically, as soon as the first signs of the protein reaction appeared, was apparently of value in mitigating the reaction. Adults were given nepenthe ℥xxv. or ℥xxx. as a routine as soon as the reaction had passed.

Record of a Fatal Case.

As noted above, one death occurred, apparently due to protein shock, associated with acute bronchitis. The circumstances were these:—

E. M., female, aged 4 years, admitted Oct. 12th, 1928, on the third day of the disease, had a short moist cough. The rash was well marked, the tongue was "white strawberry," and the fauces were intensely injected and showed some muco-purulent exudate. The pulse-rate was 138 and the temperature 100·8° F. On examination of the lungs, rhonchi were heard over all the lobes and fine moist râles were present at both bases. She was given 10 c.cm. of scarlatinal antitoxin intravenously at 7 P.M. At 7.45 P.M. she had a severe rigor, followed by profuse sweating and

collapse. At 8.15 P.M. the pulse was thready, the colour very poor, the pupils contracted, and the eyes turned upwards and squinting, and there were convulsive twitchings of the face and limbs. Half a cubic centimetre of adrenalin was given intramuscularly, followed by a hypodermic injection of camphor, ether, and olive oil, and then a pint of subcutaneous saline. The acute emergency passed, and the child appeared moderately comfortable after an hour, although pulse and colour were still not good. At 1 A.M. the child collapsed again, was stimulated as before, and again rallied. Collapse reoccurred at 5 A.M. and, in spite of all treatment, death took place at 7.30 A.M., 15 hours after admission. Consciousness was unclouded until the end.

Post-mortem Examination.—Venous congestion of all the organs was found. The lungs showed an inflammatory exudate in the large and smaller bronchi without collapse of vesicles, and there was evidence of acute bronchitis.

This unfortunate event was a matter of very real concern to us. In view, however, of (1) the very low mortality-rate and (2) the striking success of the experiment in every other way, we feel that intravenous injection is justified. Probably some deaths and much permanent damage have been obviated by its use. Care, however, should be exercised at the present stage to exclude protein-sensitive subjects as far as possible. Two further ways in which the risk can be minimised occur to us. Where there is a possibility of protein-sensitivity, a preliminary intradermal test with the serum should be done. A marked reaction would contra-indicate intravenous injection. The other suggestion is that a low-protein, concentrated and refined serum should be produced, similar to that now on the market for diphtheria. This seldom occasions any reaction, and hardly ever a severe one, when injected intravenously, even in large quantities. A word of warning may be given here against mixing different makes of serum when injecting intravenously. We believe this to be highly dangerous.

Serum Rashes.— These were very infrequent, occuring only in 11 cases, or 2·8 per cent.

Secondary Pyrexia.—This was a peculiar feature which occurred in 33 cases, or 8 per cent. of the series. It consisted of a three-day pyrexia of 100° F. or more, commencing on the fourth day after admission. Sometimes headache was present, but otherwise there was no complaint. No tonsillitis, adenitis, or other evidence of acute inflammation could be found. The condition appeared to us to be a mild and limited recurrent toxæmia, and seemed to exert little or no adverse influence on the patient. A typical chart (Fig. 3) showing this secondary pyrexia is here reproduced.

Desquamation.—This was generally absent when the antitoxin was given within the first four days of the disease, and slight thereafter, unless the rash was very intense. Since mucous or purulent discharges were practically absent, no importance was attached to desquamation in judging fitness for discharge.

Dick Test.—One hundred cases were Dick-tested just before their discharge—i.e., 15 to 20 days from the onset. Of these, 88 were negative and 12 positive.

Effect on Ward Routine.—This was very marked. Practically no nursing was required after the day of admission. The constant routine work of attending to septic throats, noses, glands, and skin was almost entirely eliminated, and considerable economy of nurses' time was effected.

Effect on Hospital Accommodation.—The reduction of the average stay in hospital to just over a fortnight enabled us to deal easily with a very considerable epidemic. Within a fortnight after the epidemic began to subside we were able to close one ward block, so rapidly were the patients discharged. In future it should be possible to allocate to other purposes half the ward accommodation previously reserved for scarlet fever.

Cost.—The cost of serum per case works out at about 15*s.* This is much more than counterbalanced by the saving effected in the reduction of patient days, staff, staff accommodation, &c.

Summary and Conclusions.

1. Intravenous antitoxin administered in the acute stage of scarlet fever stops the acute process within a few hours, prevents complications and permanent damage to health, and greatly reduces the period of residence in hospital and of abstention from work or school.

2. Certain cases should, however, be excluded until a refined serum which will not give rise to protein shock becomes available.

BLOOD-CHOLESTEROL DURING THE MENSTRUAL AND EPILEPTIC CYCLES.

BY EDWIN GOODALL, C.B.E., M.D., F.R.C.P. LOND.,

MEDICAL SUPERINTENDENT OF THE CARDIFF CITY MENTAL HOSPITAL; LECTURER ON MENTAL DISEASES, WELSH NATIONAL SCHOOL OF MEDICINE; PHYSICIAN FOR PSYCHIATRIC OUT-PATIENTS, CARDIFF ROYAL INFIRMARY.

(*Communicated on behalf of the Clinical and Laboratory Staff of the Cardiff City Mental Hospital.*)

A.—CHOLESTEROL AND MENSTRUATION.

IN a paper in THE LANCET by Robinson, Russell Brain, and Kay, on the Association of Low Blood Cholesterol with the Occurrence of Fits in Epileptics, the incidental statement is made, apparently upon the authority of Okey, that the blood-cholesterol is markedly decreased at or about the menstrual period. This statement we put to the test in our chemical research laboratory (Dr. R. V. Stanford and Mr. A. H. M. Wheatley).

Method.—The total cholesterol in whole blood was estimated, Sackett's 1925 modification of Bloor's method being employed, since Robinson, Brain, and Kay used this in their work and since we proposed at a later stage to inquire, as they did, into the cholesterol-epileptic-seizure relationship. This method has also the advantage of requiring only small amounts of blood. Okey and Boyden [2] used Bloor's method.

The patients were 12 mentally disordered women of the rate-supported class, aged between 22 and 47. They were in good health. Ten were quiet, deluded patients of the chronic class; two were quiet mental defectives. None was recent or acute, and all had been in hospital for more than one year. Each was placed on a diet of, as closely as possible, 17 calories to the pound of body-weight, composed of bread, butter, milk, meat, and potatoes. Each was kept in bed for not less than three days before the withdrawal of blood. These remarks apply likewise to the observations on epilepsy.

The 12 patients were examined for cholesterol in two phases of the menstrual cycle—viz., inter-menstrual (as nearly as possible midway between actual "periods") and intra-menstrual (during the actual time of the menstrual flow, commencing not later than the day after its inception). In each phase blood was taken on three consecutive days under conditions specified below (six estimations to each patient). In the inter-menstrual series all the patients were in bed and on the diet for three days before the first estimation. In the intra-menstrual series these conditions were observed for three or more days (up to ten) before the first estimation. The variation in the time of rest and diet in the intra-menstrual series was occasioned by irregularity in the dates of menstruation. The diet and rest were continued throughout each set of three estimations.

When the patients had all been examined in both phases of the menstrual cycle the observations were collectively known as Series A (72 estimations).

[1] Robinson, S. H. G., Brain, W. R., and Kay, H. D.: THE LANCET, 1927, ii., 325.

[2] Okey, R., and Boyden, R. E.: Jour. Biol. Chem., 1926, lxxii., 261.

the patients were then examined in both phases again, and the second group of observations was known as Series B (72 estimations; 144 estimations in all). The conditions in the two series differed as follows:—

Series A.—Blood taken 1½–2 hours after breakfast.

Series B.—Blood taken before breakfast, the patients being in the fasting condition from tea-time the day before.

In each series the time of taking the blood was about 10 A.M. The mean results of the two series are in most cases in agreement to within about 10 per cent. (in half the cases to within 5 per cent.). The agreement is somewhat closer in the inter-menstrual than in the intra-menstrual results.

Technique.—The blood was collected in prepared tubes, as follows:—

After applying tincture of iodine to the skin several c.cm. (2–8, according to the condition of the patient) were withdrawn from the superficial veins of the forearm with a 10 c.cm. sterile serum syringe, and this blood was immediately transferred to a test-tube containing about 10 mg. of lithium oxalate, and was thoroughly mixed.

Observations.

The green colour developed from the cholesterol which is used for the colorimetric comparison is very variable in shade, sometimes being yellowish-green and at other times bluish-green. This variability often makes an exact colour-comparison impossible, so that a large number of the results obtained can only be regarded as doubtful. Some of the variations found may be due to actual changes in the amount of blood-cholesterol; some, on the other hand, are undoubtedly due to the uncertainty of the colorimetric comparison, and in deciding the reliability of any particular result it is impossible to differentiate between the two causes of variation.

Table I. is based upon the figures representing the amount of cholesterol in hundredths of a milligramme (cmg.) per 1 c.cm., which corresponded with the colorimetric readings. In each of the 12 cases is shown the percentage variation of the maximum and minimum results from the mean of the three results obtained.

TABLE I. (*from Series B*).

Case No.	Inter-menstrual.			Intra-menstrual.		
	Mean.	Max. percentage above mean.	Min. percentage below mean.	Mean.	Max. percentage above mean.	Min. percentage below mean.
24	184	7	10	171	7	12
25	146	0	0	154	11	8
26	167	9	13	157	3	2
27	136	1	1	136	2	2
28	192	1	1	203	2	4
29	155	3	3	149	5	3
30	184	3	3	176	2	3
31	198	4	4	198	3	3
32	149	3	5	153	8	4
33	146	1	1	153	10	12
34	139	2	2	155	2	1
35	169	4	4	170	11	6

Robinson, Brain, and Kay (loc. cit.) obtained the following results on 32 normal female cases: maximum, 243; minimum, 152; mean, 175.

TABLE III.—*Cholesterol in Hundredths of a Milligramme per c.cm. of Whole Blood.*

—	32 normal cases.	12 female mental patients.
Maximum ..	243	206
Minimum ..	152	134
Mean ..	175	163

It will be seen that the figures obtained by us are somewhat lower than the normal values. Our series shows that the amount of cholesterol present in the blood is the same in the inter-menstrual as in the intra-menstrual period.

Table II. compares the amount of cholesterol in cmg. per c.cm. in the inter- and intra-menstrual phases in the 12 cases, the mean of the three sets of figures being given in each case for each phase. (Series B is alone dealt with; Series A is practically in agreement, and is therefore not printed.)

TABLE II. (*from Series B*).

B. CHOLESTEROL AND EPILEPSY.

Robinson, Brain, and Kay found from their study of 11 cases that in 10 the cholesterol-level, both in blood and plasma, fell in the pre-convulsive period, and the fits took place at or about the lowest point in a curve plotted to show the amount of cholesterol at regular intervals.

We examined the cholesterol in the whole blood of six cases (three males and three females) of long-standing epilepsy, with dementia to a greater or lesser extent. In each case three estimations were made in the inter-paroxysmal and three in the pre-paroxysmal phase (36 estimations in all). The time which elapsed between venesection and the fit (pre-paroxysmal period) is set out for each case in Table V. The inter-paroxysmal results (Table V.) were obtained in blood drawn at a time when the patients had been free from fits for some days.

TABLE IV.

Case No.	Sex.	Inter-paroxysmal.			Pre-paroxysmal.		
		Mean.	Max. percentage above mean.	Min. percentage below mean.	Mean.	Max. percentage above mean.	Min. percentage below mean.

			− 1	5				+ 7	22
			− 2	0				+ 4	5½

+ = higher than inter-parox. — = lower than inter-parox.

In five out of the six cases the blood-cholesterol in the inter-paroxysmal phase was fairly constant over the three days on which estimations were made;

in the sixth case (38) one of the values was considerably higher than the other two; hence the variation of the maximum and minimum from the mean was more marked than usual (Table IV). In four out of the six cases the blood-cholesterol in the pre-paroxysmal phase was fairly constant over the three days on which estimations were made; in the two remaining cases (37 and 39) the variation was more marked (Table IV.). It is impossible to say with certainty whether the variations are due to changes in the cholesterol content of the blood or to the unreliability of the method of estimation.

It will be seen from Table IV. that the mean value for the blood-cholesterol in the pre-paroxysmal phases is not markedly different from that in the inter-paroxysmal phases. The variations from the mean tend to be greater in the former.

In Table V. the results are set out in rather greater detail; the percentage variation of each pre-paroxysmal result from the mean inter-paroxysmal result is given, and also the time which elapsed between the venesection and the fit. This table shows that the pre-paroxysmal cholesterol usually tends to be slightly lower than the inter-paroxysmal value. The only marked variations are the 30 per cent. fall in Case 39 and the 19 per cent. rise in Case 37.

Table IV. shows the mean result and also the percentage variation of the maximum and minimum from the mean in the inter- and pre-paroxysmal phases for each patient. Results are expressed in hundredths of a milligramme (cmg.) per c.cm. of blood.

My thanks are due to my medical colleagues, Dr. H. A. Scholberg, Dr. J. S. I. Skottowe, Dr. J. S. Allen, and Dr. Muriel Northcote, for their coöperation. This work has been done on behalf of the Medical Research Council, for whose financial assistance my best thanks are due.

Clinical and Laboratory Notes.

A FURTHER CASE OF *BRUCELLA ABORTUS* INFECTION IN MAN.

BY J. A. CHARLES, M.B. DURH., M.R.C.P. LOND., D.P.H. CAMB.,
DEPUTY MEDICAL OFFICER OF HEALTH, NEWCASTLE-UPON-TYNE;
AND
S. H. WARREN, M.R.C.S. ENG., D.P.H. LOND.,
DIRECTOR, PUBLIC HEALTH LABORATORY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

THE physician and bacteriologist in coöperation have thrown much light during recent years upon the causation of those clinical syndromes in which an unexplained pyrexia has been the major feature. In certain of these cases the Brucella group of organisms in the form of one or other of its principal members—*Brucella melitensis* or *Brucella abortus*—has been directly implicated. The former organism primarily infects the goat and by transmission from that animal gives rise to Malta fever in man; the latter, a cause of contagious abortion in cattle, reaches the human being either through contact with contaminated uterine contents or—more commonly—in the domestic milk. Although during the last few years occasional cases of human abortus infection have been reported from Southern Rhodesia, Germany, Italy, and this country, the greater part of the work on the subject has been done in America and Denmark, where large series of cases have been collected and published by Kern[1] and Kristensen[2] respectively. English cases have been recorded by Bamforth,[3] Wordley,[4] Manson-Bahr,[5] Thompson,[6] and Harrison and Wilson,[7] and to these the following must now be added.

The Case Narrated.

The patient, aged 44, was a medical practitioner, engaged in institutional practice. He was a man of good physique, vigorous, and mentally active. His medical history included inoculation with T.A.B. in 1917 and attacks of variola major and lobar pneumonia at earlier dates. He had never been domiciled out of England except during a brief visit to Belgium in 1906, and the last eight years had been spent in more or less permanent residence at an institution two miles from Newcastle. His tastes were simple, his habits temperate, and the only one of importance and interest was that of drinking a half or even a whole pint of raw cow's milk every evening before supper. There was neither history of contact with goats nor of ingestion of their milk. The onset of his illness could be traced back definitely to Sunday, Oct. 7th, 1928, when he noticed some diminution in his ordinary robust health, and thereafter a steadily advancing malaise, which though increasing day by day, was not sufficient to prevent him from carrying out his duties. Throughout this period, which terminated somewhat dramatically on Oct. 15th, his feelings were those of lassitude, dullness, nausea, and anorexia. An intermittent headache and pain in the left foot when walking were more definite symptoms, the latter being apparently due to a plantar fibrositis. Although the temperature was never taken until Oct. 15th, there was a vague sensation of fever especially in the afternoon and early evening. Slight epistaxis occurred on one occasion, and there was evidence of some intestinal irregularity in that his daily normal stool was replaced by a single large loose evacuation. Before the night of Oct. 15th his sleep had been disturbed on one or two occasions by slight sweats, but on that evening a definite rigor, followed by excessive and exhausting perspiration, led to the taking of his temperature, which was found to be 99·6° F. From that time he remained in bed, and to his previous symptoms of malaise, headache, and anorexia there were added irritability, insomnia, and continuing fever. The morning temperature remained practically stationary at about 99° F., but these remissions were followed by afternoon exacerbations which, becoming progressively higher day by day, ultimately reached 102° F. The pulse lagged relatively behind the temperature, though there was never any indication of a true bradycardia. The drenching sweats, especially at night, continued, but the fibrositis disappeared, and the moderate diarrhœa was replaced by an obstinate constipation. These were the only symptoms and signs during the second week of the disease. At this stage he was seen by a consulting physician on whose advice a specimen of blood was submitted to a local laboratory for agglutination tests with the enteric group. The report of this investigation stated that the serum had agglutinated *B. paratyphosus* A solely, and that in a dilution of 1 in 50. In view of these findings the patient was admitted to the City Hospital for Infectious Diseases, Walker Gate, on Oct. 24th.

On admission his temperature was 100·6° F. and his pulse-rate 96. There were no signs of any clinical significance in the respiratory or nervous systems. The skin was clear and there was no evidence of present or recent rashes or herpetic eruptions. A decided congestion of the pharynx was apparent, and the tongue was dry and heavily furred. Examination of the undistended abdomen revealed some diffuse tenderness in the left hypochondrium and along the line of the descending colon. The spleen, though not palpable, appeared on percussion to have an enlarged area of dullness. The urine was apparently normal on investigation by the ordinary routine tests, and the diazo reaction of Ehrlich was negative. Adventitious murmurs were not audible at any of the cardiac valvular areas, though the heart sounds and pulse were softer than normal. Irregularities of rhythm were entirely absent. The systolic and diastolic blood pressures were respectively 110 and 80 mm. of mercury. A rough leucocyte count showed: total cells, 7500; polymorphonuclears, 4500 (60 per cent.), and a slight absolute increase in the small lymphocytes 2250 (30 per cent.).

Throughout the first week in hospital (Oct. 24th–31st) the patient's temperature continued to range from 98·4 to 103° F., but the evening elevations on the whole were lower and the morning remissions more definite. The sweats, however, persisted as an unpleasant and exhausting feature, and the pulse-rate still appeared to lag relatively behind the temperature. The bowels remained confined though the tongue cleaned, the pharyngitis abated, and the appetite improved. A certain degree of testicular tenderness and swelling was manifest throughout this time. The blood pressure increased slightly until the systolic and diastolic figures were 118 and 90 mm. of mercury. There was no evidence of any Addisonian pigmentation. The blood count showed: erythrocytes, 4,500,000; hæmoglobin 90 per cent.; colour-index, 1; leucocytes, total 6800, polymorphonuclears, 3100 (45 per cent.); eosinophils, 2

per cent.); small lymphocytes, 2500 (38 per cent.); ge lymphocytes, 750 (11 per cent.); transitional leuco- tes, 140 (2 per cent.).

Diagnosis.—Even on his admission to hospital the appear- ce of the patient (which was that of a mentally alert n interested in his condition), the spikey temperature, absence of rash, the meagre abdominal and intestinal ns, the negative diazo reaction, and the comparative ity of paratyphoid A fever in this country, all combined throw doubt on the original laboratory diagnosis. The idal reaction was repeated at the University of Durham cteriological Laboratory on Oct. 25th, when it was found at the serum agglutinated *B. paratyphosus* A and B in utions respectively of 1 in 25 (trace) and 1 in 25 (faint ce). Cultures of blood and fæces made on the same te, and again from fæces on the 30th were all negative the enteric group. In further Widal tests made on t. 31st, the serum diluted to 1 in 25 produced only a slight ce of agglutination with each of the three organisms, *typhosus*, *B. paratyphosus* A and B, and was completely gative in all other dilutions. It was considered that these glutination titres were compatible with a persisting or rexially reactivated immunity to the organisms in estion, consequent on the patient's inoculation against m 11 years previously. The diagnosis of an enteric ection was accordingly discarded. Certain other clinical restigations were undertaken—radiography of the chest, amination of the nasal sinuses, urine cultures, examina- n of blood films for malarial parasites—but the results of se, as also of a prolonged search for the presence of any m of occult or focal sepsis, were all negative.

On Oct. 31st the blood was tested against emulsions of . *abortus* and *Br. melitensis*, and the following results re obtained :—

TABLE I.

Organism.	Serum dilution.							
	1 in 25.	50.	125.	250.	500.	1000.	2500.	5000.
abortus ..	—	—	+	+	+	+	+	—
melitensis ..	+	+	+	+	+	+	±	—

These agglutinations were repeated on Nov. 6th with um which had been heated to 56° C. for half an hour, l also with unheated serum. (The object of heating the um was to ensure destruction of non-specific agglutinins— ., typhoid, dysentery, &c.) The results of these agglutina- ns are given in Table II., and upon them, in the absence

ny caprine source whence *Br. melitensis* might have been nsmitted, the diagnosis of infection by *Br. abortus* made. On the same date (Nov. 6th) cultures of blood urine were made in accordance with the special technique cribed later in the article, and guinea-pigs were injected peritoneally with the patient's blood. The absolute of the diagnosis—namely, the isolation of the causal anism, which was sought by these procedures, was ortunately not obtained. This result was not entirely xpected, as the specimens had been taken towards the of the pyrexial period.

Further Progress.—The subsequent history of the case entirely uneventful. The temperature, having reached mal after a month, did not again exhibit any pyrexia, had been normal for over a fortnight when the patient discharged from hospital on Nov. 24th. With the tement of the pyrexia all the remaining signs and ptoms subsided. The sweating ceased, the orchitis inished, the spleen was no longer enlarged, and the od pressure gradually rose until on discharge the systolic diastolic pressures registered 128 and 90 mm. of mercury ectively. Treatment throughout was directly purely he alleviation of symptoms. Intravenous injection of curochrome had been decided upon in the event of a rn of the pyrexia.

Epidemiological Inquiry.

The patient was accustomed to drink at least half a pint, and frequently a pint, of milk every evening before supper. This was fresh, raw, often warm milk from the afternoon milking of the institutional herd of seven cows. In February, 1928, one of these cows had aborted without apparent cause, and though continuing for a period to give milk in moderate quantities it had ceased to do so about the end of September. No other cow in the herd had aborted, and all were in good health and full milk.

It was decided to submit the blood of all the animals of the herd to agglutination tests with the *abortus-melitensis* group and to carry out an inquiry as to the presence of such organisms in the milk. Local difficulties rendered this comprehensive routine investigation impossible, and it was reluctantly given up. It was found possible, however, to obtain a specimen of secretion from the aborted cow's udder (a liquid which at that date could hardly be called milk), and this was used as the material for further bacteriological investigations.

On Nov. 14th two female guinea-pigs were inoculated intraperitoneally with the fluid from the cow's udder. One, No. 1498, was given 5 c.cm. of the uncentrifuged material, and into the other, No. 1499, 1 c.cm. was injected. The guinea-pigs were killed on Dec. 28th, 1928. Both showed lesions suggestive of a Brucella infection, though actually the one receiving the smaller quantity gave evidence of the more marked lesions. No. 1498 showed definite enlargement of the spleen with dark nodules and a minor degree of enlargement of the lumbar glands. There was no sign of any metritis. No. 1499 showed very marked enlargement of the spleen with well-defined dark nodules. The lumbar glands were slightly enlarged, and inflammatory lesions with white necrotic centres were present in both horns of the uterus. The blood of both animals was kept for agglutination test and cultures were made from the two spleens and from the uterine lesions. A special culture medium—namely, the liver extract medium as used by Huddleston, Hadley, and Torrey,[8] but without the addition of gentian violet—was employed in sloped tubes. These tubes were inoculated in duplicate, one set being placed immediately into a closed glass vessel to which 10 per cent. by volume of carbon dioxide was added from a carbon dioxide cylinder as advocated by Theobald Smith.[9] All the cultures were incubated in the 37° C. incubator. The other batch of cultures which had not been put into the carbon dioxide chamber was examined next day. One of the tubes inoculated from the uterine lesions showed many colonies but none were present elsewhere. The colonies on this tube were then marked with a blue pencil and all the tubes were placed into the carbon dioxide chamber and reincubated. After three days' incubation there was some suggestion of growth, but it was not until the end of four days that the tubes were taken out and examined thoroughly. The tubes inoculated from the spleens all showed well-defined growth in the form of discrete round colonies which were dome-shaped, slightly yellow in colour, transparent, and easily emulsified. Microscopically they were found to consist of small non-motile Gram-negative bacilli. After subculture on to liver extract slopes and incubation in the carbon dioxide chamber a profuse growth was obtained, and from this an emulsion was prepared for agglutination tests. On further incubation a few similar colonies developed on the cultures from the uterine lesions. The blood of both animals showed well-defined agglutinins to both *Brucella abortus* and *Brucella melitensis*. (Table III.)

TABLE III.

1499 ..	±	+	+	+	+	+	±	—	—

(*b*) *To Br. melitensis.*

1498 ..	+	+	+	±	—	—	—	—	—
1499 ..	±	+	+	+	+	±	—	—	—

The organisms cultivated from the two spleens and the inflammatory areas in the uterus agglutinated to titre with the abortus serum supplied by the University of Oxford Standards Laboratory.

We may conclude, therefore, that the isolation of the organisms from the spleen and the presence of

agglutinins in the guinea-pigs' blood clearly showed that the cow from which the sample was taken was infected with *Brucella abortus*, and may presume that this animal's milk was the probable source from which our patient had been infected. We would add that we are well aware that the inoculation of milk into guinea-pigs is not necessarily the best and certainly not the quickest method of demonstrating *Brucella abortus* in cow's milk, but it has been definitely shown to be satisfactory, and at the time the material was obtained for investigation there was no suitable culture medium available.

Our thanks are due to Prof. Harold Kerr, medical officer of health of Newcastle-upon-Tyne, for permission to publish the report of this case, and for his interest in the investigation.

A CASE OF *BACILLUS ABORTUS* INFECTION IN ENGLAND.

BY A. T. TODD, O.B.E., M.B. EDIN.,
LECTURER IN PATHOLOGY AND ASSISTANT PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

IN view of the articles on this subject in THE LANCET of Dec. 29th, 1928, a brief account of a case diagnosed in 1927 may be of interest. The case was seen once only, in consultation with Dr. A. N. Heron of Bristol on Jan. 1st, 1927. She was nursed at her home.

The patient, a spinster aged 31, had complained for three weeks of rheumatic pains, irregular fever, and constipation. A complete record of her temperature was not available but, taken on alternate days, usually in the morning, it varied between 99·6° and 101° F. The case was rather striking on account of the negative clinical findings; a trace of albumin had been noted on two occasions. She had been treated unsuccessfully with hexamine and salicylates. Her previous history was unimportant. The family history showed a tuberculous taint in the father. Examination revealed a few acne-like spots, a furred tongue, tenderness of the pectoral muscles, and slight dullness of the right base, but no abnormality of breath sounds. In all other ways the result of examination was negative. The blood showed 100 per cent. hæmoglobin; 7400 white cells per c.mm. A differential count showed: jügendlich 1·0 per cent., stabkern 5·6 per cent., segmentkern 68·0 per cent., lymphocytes 20·3 per cent., transitionals 3·9 per cent., eosinophils 0·6 per cent., mast cells 0·6 per cent. The red cells showed no abnormality. The urine gave a hydrogen-ion concentration of 7·4, and contained no albumin, sugar, blood, bile, or indican. The amount of urobilin was 0·02 per cent. Deposit showed a little pus, but no casts or red cells. A film showed a few Gram-positive cocci and culture gave a diphtheroid bacillus, streptococci, and a short Gram-negative bacillus which showed the cultural characteristics of *B. abortus* of Bang.

A specimen of the milk consumed at the house gave a positive culture of *B. abortus*. The patient's serum agglutinated a standard culture of *B. abortus* up to a dilution of 1/10,000; it agglutinated *B. melitensis* to a lesser titre, but the figure in my notes is now illegible. *B. typhosus* was agglutinated to 1/50; *B. paratyphosus* A and B were not agglutinated. Her serum agglutinated the *B. abortus* isolated from her urine up to 1/12,000; it agglutinated the *B. abortus* isolated from the milk in dilutions up to 1/8000.

An autogenous vaccine was prepared and administered, but appeared in no way to influence the pyrexia. Treatment was otherwise symptomatic, and the pyrexia continued. In view of the family history and the exhausting nature of the illness, a watch was kept for pulmonary lesions; late in February, 1927, a cough with sputum appeared and the sputum showed tubercle bacilli. She was transferred to the Nordrach-on-Mendip sanatorium.

It is regretted that further work was not carried out on this case; the excuse is that intensive work on another problem was in progress at that time.

I have to thank Mr. E. Guise, of the Department of Pathology, for help in the isolation and serological investigations of this organism. It may be added that agglutination tests with the serum of a few other cases complaining of "rheumatism" at this time gave completely negative results with two strains of *B. abortus*.

A BACTERIOLOGICAL INVESTIGATION OF THE PRESENT INFLUENZA EPIDEMIC.

BY DAVID THOMSON, O.B.E., M.B. EDIN., D.P.H.
HON. DIRECTOR, PICKETT-THOMSON RESEARCH LABORATORY, ST. PAUL'S HOSPITAL, LONDON;
AND
ROBERT THOMSON, M.B. EDIN.,
PATHOLOGIST TO THE LABORATORY.

SEVERAL years ago we began to record systematically by means of extensive microphotography the bacterial flora of the human body.*

Special attention was devoted to the respiratory tract. After taking thousands of photographs it was concluded that the bacterial flora, and more especially the streptococcal flora of the respiratory tract, was enormously complicated, containing over one hundred varieties. The task became so gigantic that we began to realise that unless simpler and more rapid methods of recording could be devised we would never be able to clear up the extraordinary chaotic condition of our knowledge of the subject.

A New System of Investigation.—Fortunately, during the past year we have managed to achieve the simplicity and speed of work. The system we now adopt is to photograph the cultures from the human material on Crowe's chocolate blood-agar medium. This medium we have found is by far the most differential of all culture media. It has an extraordinary power of making the various species of germs show their individuality by the appearance of their colonies. The variety and even beauty of appearance and design of the colonies as seen on the medium through a stereoscopic microscope is very striking. We commenced, therefore, to photograph the cultures on Crowe's medium on an extensive scale. Our methods of taking this type of micro-photograph have continuously improved and have now attained a high degree of perfection and simplicity. During the past eight months we have worked on a definite system as follows:—

1. Cultures are taken from the throat and sputum of one of ourselves every week during the whole year round. The photographic records of these cultures on Crowe's medium are kept in albums and copious notes are taken of the nature of the bacteria found.

2. Photographic records of cultures from the sputum and throats of other members in the laboratory are taken at less frequent intervals.

3. When a cold or feverish attack occurs in any member of the staff frequent cultures are then taken and photographed.

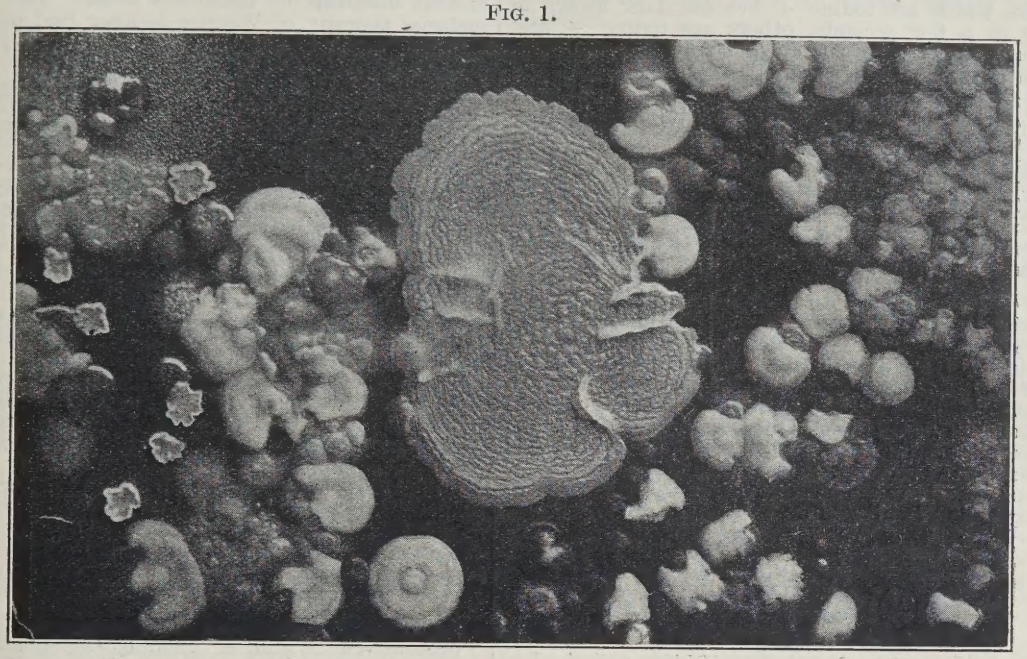
The photographs taken during the period of catarrhal infections are then compared with those taken when the individual was in good health, to see if any new bacterium has arrived in mass, which would account for the catarrhal condition.

Results.—The results obtained by the above method of investigation are very instructive and may be described shortly as follows: 1. The bacterial flora of the respiratory tract is chiefly streptococcal. The streptococci as a rule make up 90 per cent. of the total flora. 2. The streptococcal flora is constantly varying every week, even in health. 3. When a definite catarrh or cold occurs one can as a rule (on investigating the photographs carefully) place one's finger on the suspected organism. 4. Cultures from the nasopharynx or sputum of persons suffering

* These photographs are being published extensively in the Annals of the Pickett-Thomson Research Laboratory. The journal was started chiefly with this purpose in view, as the expense of plates in ordinary publications is prohibitive.

from the influenza of the present epidemic invariably show large numbers of colonies of a definite streptococcus which appears to us to belong to the pneumococcus group. 5. Cultures from persons suffering from sporadic colds previous to the epidemic did not show this pneumococcus-like organism, but other varieties of streptococci were usually incriminated. 6. The organism which is occurring in large numbers in the present epidemic is quite different from the streptococcus described by us as causing the influenzal colds of two years ago. 7. We would suggest, therefore, that so-called influenza epidemics may be due to virulent streptococcal infections of the respiratory tract, and that these streptococcal infections may vary with different epidemics.

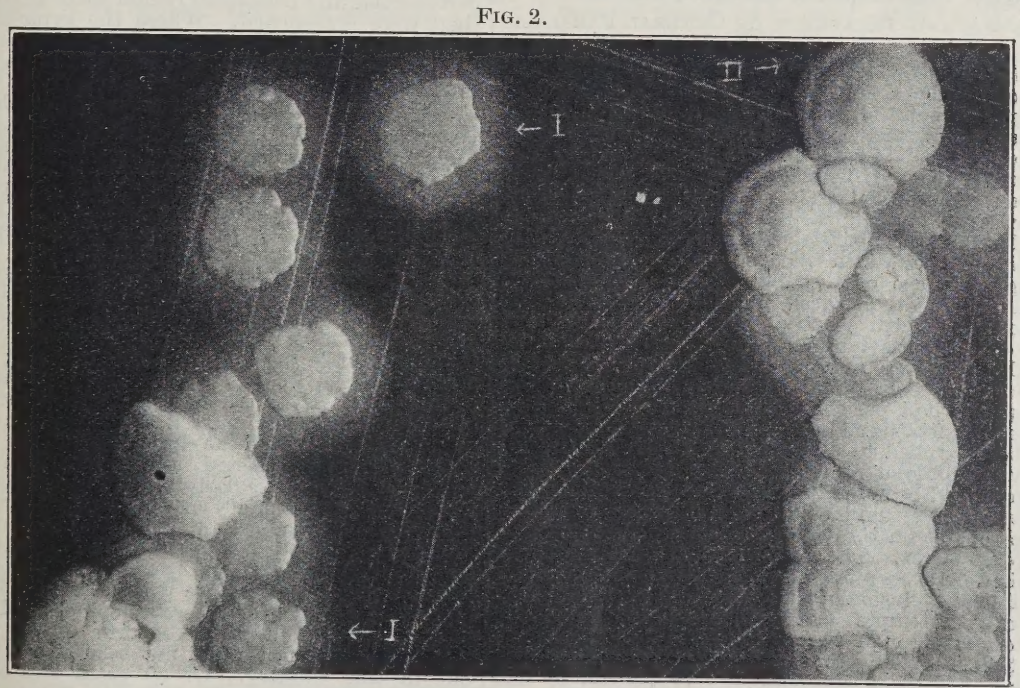
FIG. 1.



Culture on Crowe's medium from throat, September, 1928, before influenza epidemic. The colonies seen on Fig. 2 only appeared constantly in the present epidemic. Figs. 1 and 2 are magnified 16 diameters.

A New Iodine Test.—In the course of our investigations we discovered a rapid new test for the differentiation of the colonies of streptococci and other

FIG. 2.



Culture on Crowe's medium from nasopharynx of case of influenza, January, 1929. I shows type of colony constantly present in large numbers, apparently a species of pneumococcus. The photograph does not show the highly glistening appearance of the colonies, partly because the plate had dried somewhat before the photograph was taken. II is a diphtheroid bacillus.

organisms. This test, which is described in full detail in the Annals of the Pickett-Thomson Research Laboratory, Vol. IV., consists simply of placing a drop of Lugol's solution over the colony. Some colonies which are iodine + become dark brown in colour in a few seconds, others are iodine − and remain unaffected by the Lugol's solution.

The Question of Mutation.—Our observations do not lead us to believe that mutation occurs to any great extent in the streptococcus group of bacteria. They remain extraordinarily true to type in their colony appearances on Crowe's medium. We have photographed over 50 strains of streptococci from the National Collection of Type Cultures (Lister Institute) at intervals of a year, and we find that the colonies remain identical in appearance after continuous subculturing for that period of time.

We did not intend to publish any work on the bacterial flora of the respiratory tract until we had obtained many more records, but we consider it our duty to write the above short note drawing attention to the constant presence of a pneumococcus-like streptococcus in the sufferers from the present epidemic. This organism is bile soluble. The colonies on Crowe's medium are flat, moist, opalescent, and glistening, and surrounded by a wide greenish-yellow zone of bleaching. The illustrations reproduce two photographs of cultures on Crowe's medium.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF PSYCHIATRY AND NEUROLOGY.

A JOINT meeting of these Sections was held on Feb. 12th and 14th. On Feb. 12th the chair was taken by Sir MAURICE CRAIG, President of the Section of Psychiatry, and on Feb. 14th by Mr. DONALD ARMOUR, President of the Section of Neurology. The subject of discussion was the

PROGNOSIS AND TREATMENT OF GENERAL PARALYSIS OF THE INSANE.

Dr. W. H. B. STODDART said that formerly it had been generally agreed that a diagnosis of general paralysis meant 100 per cent. incurability and death within a few years. Natural remissions were known to occur, but information was lacking as to the percentage of cases in which they took place. The London County mental hospitals reported that 2·6 per cent. of their cases had improved before the introduction of malarial therapy. Dr. Stoddart himself had obtained 25 per cent. of remissions through the use of hexamine, given with brandy, and 17 per cent. of these had not relapsed. Other methods for which curative value had been claimed were either antisyphilitic or pyrexial. The usual specific drugs were of no avail because they could not enter the cerebro-spinal fluid. Injection into the lumbar sac had proved too dangerous. Marinesco's method of intrathecal injection of salvarsanised serum had been applied to paralytics by G. M. Robertson, and very different reports had been received. Many attempts had been made to introduce salvarsanised or mercurialised serum into the subdural space or lateral ventricle, but on the whole clinical amelioration had been but slight. The cerebro-spinal fluid might be modified or even rendered normal, but the effect on the clinical evolution of the disease was very doubtful. Recently, attempts had been made to introduce substances through the occipito-atlantoid ligament, but this was dangerous and unnecessary, and the method had been discredited. Tryparsamide had been introduced in America for neurosyphilis, and varying views were held about its value in general paralysis. There was a risk of optic atrophy in 4 or 5 per cent.

The value of pyrexia had been known for many years; in 1848 there had been a discussion of the favourable effect of malaria on insanity, and physicians of the time had discussed the advisability of removing mental hospitals to malarious areas. The induced malarial therapy of Wagner-Jauregg had been tried in a number of hospitals in London and 33 per cent of the cases had been discharged much improved, the figure rising to 60 per cent. if only recent cases were included. Even if no remission took place there was marked improvement in the general condition, and subsequent salvarsan treatment reduced the mortality from 32 to 6 per cent. Viennese workers claimed 83 per cent. of remissions with return to work. There seemed no choice between the use of mosquitoes and of malarial blood. Some patients would not take malaria properly, and for these all ways of inducing pyrexia had been tried: streptococcal, staphylococcal, typhoid, rat-bite fever, *Bacillus pyocyaneus* or *proteus* and tuberculous vaccines, and the subcutaneous injection of sodium nucleinate, proteins, milk, and other substances. With almost any form of treatment remissions could be obtained in about 20 per cent. but the rate was very much higher with malaria, and this must be regarded as the treatment par excellence. The contra-indication was any poor general condition such as advanced age, heart or kidney disease, tuberculosis or intercurrent malady, or undue tendency to paralytic wasting. Often the cerebro-spinal fluid was found to be normal some months after malarial treatment, but no importance was to be attached to a treatment that produced a normal cerebro-spinal fluid without any clinical effect.

Sir JAMES PURVES-STEWART suggested the name "progressive syphilitic meningo-encephalitis" to clarify our conception of the condition. There were two types of syphilitic encephalitis, he said: Interstitial, which was amenable to antisyphilitic remedies, and parenchymatous, accompanied by toxic and later by degenerative changes in the nerve-cells. The consensus of medical experience showed that in the second form the most assiduous course of anti-syphilitic drug treatment usually failed to arrest the progress of the disease. This was because the drugs failed to reach the diseased nerve-cells owing to the perivascular and perineural lymph space behind which they were entrenched. Where the syphilitic toxin could get it was reasonable to expect the antitoxin to go; at present, however, the biochemist had not yet produced this substance. Sooner or later it would be isolated and would prove as valuable as diphtheria antitoxin. More modern methods attempted to prevent neurosyphilis by stamping out the disease in its early stages—despite the claim recently made by a Norwegian investigator that early treatment failed to cure the original disease and diverted it to unnatural channels, thus actually producing neuro-syphilis. True specific treatment had not yet been found, as shown by the fact that the serological reactions often remained positive; so long as this was the case no one was justified in claiming "cure." The early preparalytic group was the most hopeful; there was little justification for submitting to treatment patients in whom cortical degeneration had commenced. Pyrexial treatments—of which benign tertian malaria had proved the most convenient—undoubtedly modified the clinical symptoms, but some patients were unaffected, and the method was not devoid of risk, particularly from cardiac failure. The reason for the diversity of opinion on its value was the varying standard of so-called recovery, which might mean simply transfer to care of friends or might ignore serological findings. Sir James Purves-Stewart had not met a single case where malarial treatment alone had brought the cerebro-spinal fluid back to normal. The optimistic reports of tryparsamide treatment in America had not been altogether borne out in this country. Of 20 cases treated at the Maudsley Hospital by W. S. Dawson two had died, 13 had shown clinical improvement, and seven serological improvement, but only in two had the Wassermann reaction become negative in the cerebro-spinal fluid.

In no case was any result obtained that might not have been obtained by the administration of other compounds. The best method was simple intravenous administration of 1 to 3 g. weekly, perhaps for a year, followed up by a course of bismuth, arsenic, or mercury.

Intracisternal Injection of Salvarsanised Serum.

Sir James Purves-Stewart said that salvarsanised serum compared very favourably with the other two methods of treatment, and presented detailed tabulated reports of 24 private patients treated by intracisternal injection, a technique that was not difficult when once mastered. He had always followed up malarial or any other form of treatment by a course of injections of autogenous salvarsanised serum, given fortnightly for six or eight fortnights. Usually the patient showed no reaction—at most a mild pyrexia. Antisyphilitic treatment was given in the intervals and the results were carefully checked by serological examinations of the blood and cerebro-spinal fluid. The amount of salvarsan present in the serum must be extremely small; the effects were perhaps due to antibodies or to protein shock. If the serum were put into the lumbar region, very little of it reached the ventricles. Serological without clinical improvement might be obtained from the use of this method alone, but the best results came from malarial therapy followed by injection. Whatever method was used, the standard of recovery should include serological reactions in the blood and cerebro-spinal fluid as well as clinical remission.

Erroneous Diagnoses due to Serological Examinations.

Dr. JOHN BRANDER said that serological examinations had introduced into the diagnosis of general paralysis an added source of confusion, and there had been a tendency for some years to include neurological and mixed types merely on the basis of serology. These latter used to be called "insanity with gross brain lesion"; they usually responded to treatment, and their prognosis was much less grave than that of general paralysis. The relative proportions of the two groups in any given series might produce very varying results. Routine examinations had shown that many conditions other than general paralysis might present a similar serological picture, and errors in diagnosis were much more frequent than was supposed. For instance, a maniacal case of dementia præcox had been admitted to hospital 19 years ago; later he had been diagnosed on serological findings as general paralysis. Without any treatment the patient was still alive and well, and still a dementia præcox, though now with a normal cerebro-spinal fluid. Dr. Brander's experience gave no support to the theory that general paralysis was changing its nature. Instead of assuming a change of type, we should guard against change of diagnostic standards.

He had examined two series of records of paratics at Bexley Heath, before and after malarial treatment respectively—i.e., in the years 1910–14 and 1920–24 when malaria had been given to all who were not too exhausted for it. On the whole the expansive types did best and the tabo-paretic and stuporose worst, but the type of case did not seem to have much influence on the prognosis. Sometimes later cases did better than apparently early ones. There was no association between the duration or severity of the malaria and the results. Of those followed up, 0 per cent. showed a decrease of the Wassermann reaction in the cerebro-spinal fluid, while 10 per cent. showed increase. Twice the fluid had become entirely normal. The gold curve and the protein content had improved in 70 per cent. and the cell-content was diminished in all. The Wassermann reaction in the blood had decreased in 50 per cent. and increased in 1 per cent.; it had become negative in one patient. Of the 19 cases remaining in hospital 15 showed marked diminution of previously gross changes in the cerebro-spinal fluid, five had a negative Wassermann reaction in the fluid, and four a negative gold curve. There was no apparent relation between these changes and clinical progress. Malaria alone seemed able in many cases to establish a gradual elimination of the virus of syphilitic encephalitis, but if the disease-process had attained a certain degree of severity the patient might continue to manifest progressive symptoms which were not of an actively syphilitic nature.

Dr. E. D. MACNAMARA said that induced malaria offered more hope of amelioration than any other form of treatment, especially if some form of anti-syphilitic therapy were given as well. Relapsing fever and antichancroid vaccine were said by some workers to be less dangerous than malaria. The spirochæte had been found in the cortex of patients who had had malarial treatment. Natural malaria before or after syphilis did not modify the latent period between infection and the appearance of general paralysis. The early stage might last for years and be improved by any kind of treatment, including the lapse of time. It was questionable whether this stage was really an early stage of general paralysis or only a meningovascular disease which might never become paralysis. Serological changes in the cerebro-spinal fluid did not always herald general paralysis or tabes. The recovery-rate now was much the same as it had been in the first third of the last century; possibly it was high because we now included many cases which were not really general paralysis at all.

Major F. H. STEWART described a modification of malarial treatment which gave equally good results with less danger and suffering to the patient. The infection, induced by 6–10 c.cm. of malarial blood, was stopped with quinine after one or two rigors and active tryparsamide treatment was instituted. The patient was reinoculated at intervals of two months until he recovered or appeared hopeless. The aborted fever was usually sufficient to restore ability to work or to return home. The later malarial attacks tended to die out spontaneously.

Dr. G. DE M. RUDOLF pointed out the difficulty of saying that a paralytic had "recovered," as untreated cases had been known to have remissions extending over many years. The only "recovery" was a good remission lasting to the average age of death; return to clinical or serological normality did not signify recovery. He then related the findings of the committee appointed in 1925 to report on the value of malarial treatment in the London County mental hospitals. Of 227 patients not treated with malaria 2·6 per cent. had been discharged; of 191 treated with malaria 33·5 per cent. had been discharged. Of 191 unselected cases at Claybury 31·4 per cent. had been discharged. Of 89 who had had malarial treatment alone 37·1 per cent. had been discharged; of 28 who had had malaria and sulfarsenol 59·6 per cent., and of 14 who had had malaria, mercury, iodide, sulfarsenol, and tryparsamide 37·5 per cent.

Dr. C. C. WORSTER-DROUGHT described his experience of malaria followed by intravenous novarsenobillon at a neurological hospital. The diagnosis had been based on clinical condition, a positive Wassermann reaction in the blood, and cerebro-spinal fluid and a paretic type of Lange gold curve. Of 35 cases treated in 1923–24 20 per cent. were now at work, 50 per cent. were improved but could scarcely be called useful members of society, 20 per cent. were in mental hospitals or dead, and 10 per cent. had not been traced. There was a perplexing difference between these results and those reported from Vienna. The Wassermann reaction had become negative in a large proportion, but not until after two years. The somatic type with predominating physical symptoms had an infinitely better prognosis than the mental type. Blood-transmitted infection was preferable because the rigors developed more rapidly and seemed to be less exhausting and because they were more easily controlled.

Experience with Relapsing Fever, Saprovitan, and Milk.

Dr. A. A. W. PETRIE described the reaction of patients to relapsing fever; three or four pyrexial periods usually occurred, but the only sequela had been temporary Bell's palsy in four cases. Seven patients had been

discharged, five had shown improvement, nine had been unchanged, two had become worse, and three had died. At times inoculation with relapsing fever might prove dangerous and difficult to control. Of 11 patients injected with saprovitan only one had shown real improvement, although reliable pyrexia had been produced. Milk injection had given little result, and the pyrexia produced by this method seemed to depend upon the presence of organisms in incompletely sterilised fluid and not upon a true protein reaction.

The Board of Control Investigation.

Surgeon Rear-Admiral E. T. MEAGHER described the investigation he had made for the Board of Control into the results of malarial treatment in the 41 mental hospitals which had used it, compared with the results of other treatments in the 97 other hospitals. All the cases had been followed up and those discharged had been personally visited by himself. In the two years 1923–24 there had been 1173 direct admissions of general paralytics; of those not treated by malaria 87 per cent. were dead, 10 per cent. remained in hospital, and 3·4 per cent. had been discharged. These figures, therefore, constituted a standard by which to measure the results of malarial treatment. Of the 438 patients treated with malaria up to the end of 1924 43·6 per cent. were dead, 31·7 per cent. were still in hospital, and 24·7 per cent. had been discharged. Even in the best of all the non-malaria hospitals the percentage of dead was 65. The same superiority of malarial treatment was revealed whatever tests were applied to the figures. The patients remaining in hospital lived more natural lives and were in a better state up to the time of their death. Of the 134 discharged 108 remained discharged, so that only one in five of them might be said to have "failed." Of the cases not treated with malaria one-half failed. Seventy-seven were following their former avocation, 10 were degenerating, and 11 had not been traced. The recovered ones all showed a surprisingly high standard of neatness in dress, of insight, judgment, and memory, and expressed anxiety as to the future. Their speech was normal and they had no tremor, though many looked as if they had been through a severe illness and were more tired than before. Of the total of 1597 patients treated with malaria in the quinquennium 1922–27 34 per cent. had died, 41 per cent. remained in hospital, and 25 per cent. had been discharged. Of those who had died one-quarter had died within a month of malarial inoculation, and this process certainly seemed to precipitate death in many cases, although Wagner-Jauregg claimed that he had eliminated early fatalities by the routine use of cardiac stimulants at the onset of each febrile attack. There was evidence on all hands that malarial treatment required reinforcement; all the continental clinics were using arsenic in some form as well. The result of the inquiry might be summarised: malarial therapy is of value in extending life, in improving the mental and physical state of the patient, and in allowing 20 per cent. of cases to resume normal life; it appears to be the best form of treatment at present known.

The Use of Tryparsamide.

Dr. THOMAS TENNENT said that tryparsamide had first been used for neurosyphilis in 1923. Since Dawson's work 33 more cases had been treated at the Maudsley Hospital by 12 weekly injections of 3 g. Malaria was used as well and the tryparsamide was continued throughout the fever. There was no evidence of cumulative effect. Treatment could be continued for two or three years if the serological tests remained positive. Remissions had been obtained in 32 per cent. of cases, and these patients had been living normal lives for one to four years. The chances of improvement definitely diminished with delay in initiating treatment. Many patients showed clinical improvement without serological changes, but all of them had a reduction in the cell content; the Wassermann reaction and globulin came next in order of improvement and the gold reaction was the most resistant. The Wassermann reaction remained positive in the blood more often than in the cerebro-spinal fluid. It was impossible to say at what point serological improvement would take place, and there was no parallelism between serological and clinical improvement except that in the later stages all patients who improved physically also showed serological changes. The converse, however, was not true. Two cases of amblyopia had occurred, but had improved when the treatment was interrupted. Tryparsamide was a valuable drug, but was best combined with pyrexial treatment.

Dr. J. G. GREENFIELD said that most of the malaria-treated paralytic patients who came to post mortem at Queen-square had died from lung complications. The chief changes in the brain were enormous excess of small round-celled infiltration, in which the leucocytes exceeded the plasma cells. In later stages early, or even gross, gummatous change might be seen. There was a rapid and most striking disappearance of spirochætes. It was not surprising that this acute encephalitis with malaria infection caused a great tendency to death from intercurrent infection. It explained the necessity of reinforcing malarial treatment by salvarsan. The changes in the cerebro-spinal fluid were more evidences of "scarring," of the process of clearing up the inflammation, than of continued active infection.

Dr. DAVID NABARRO said that the cerebro-spinal fluid of every syphilitic should be examined at the onset of treatment and at the time of discharge. Evidence of central nervous system involvement was often seen at Great Ormond-street in the form of fits, spasticity, or mental deterioration. If the Wassermann reaction were positive in blood and fluid and the gold curve were paretic, the child was then regarded as a probable paralytic. Cisternal puncture had been done on a number of children and was not difficult. He described the treatment of several children, particularly one reported in THE LANCET [1] who was still well and progressing. Malaria had been given to four or five general paralytics without marked benefit. Intracisternal puncture had proved much more satisfactory, but the best treatment was to forestall neurosyphilis altogether.

The Present Wagner-Jauregg Technique.

Dr. HANS DEUTSCH (St. Louis) described the method employed at Vienna, as differences in technique might account for varying results. The malaria was always inoculated from patient to patient; after several passages the disease was no longer transmissible to mosquitoes and became extremely sensitive to quinine. Three half-grain doses would stop the rigors. If the patient did not react to subcutaneous inoculation, 5–10 c.cm. were given intravenously. If this produced no result, mixed typhoid vaccine—about 25 million—was given, and this usually produced a pyrexia on which malarial rigors supervened. The number of rigors was usually 8–12, but the patient's condition might make it necessary to interrupt the treatment and resume it after a few months' rest. This reduced the mortality-rate, especially in elderly patients, and the only difference in the second inoculation was that it usually produced a rigor without the help of TAB. Digitalis was given to every patient and six salvarsan injections were always administered. Malarial therapy was not a substitute but an aid to specific treatment in syphilis. Malaria was never given alone. A second course, a year or more after the first, was beneficial and prolonged the remission. Patients reported regularly for serological and mental tests. If no rigors could be obtained with malaria relapsing fever was given and followed by salvarsan. The spirochæte was a mesoderm organism which could only enter the ectoderm when the glia had been broken down. The benefit of the treatment lay in stimulating the ectodermal defence preventing the spirochæte from entering the cortex and limiting it to the perivascular space when

[1] THE LANCET, 1927, ii., 692.

alvarsan could get at it. It was not allowable to peak of "cure" but merely of "remission," for ervous tissue could never regenerate.

The Concept of Neurosyphilis.

Dr. GLEN DUNCAN observed that an "early" case vas not necessarily one which had only had mental ymptoms for a brief period; the severity and apidity were of greater prognostic significance. The ental hospital could not continue treatment up to ecovery; it was bound by law to discharge patients s soon as they were fit for liberty. It was for the eurological hospital and general practitioner to see hat treatment was continued, and there should be loser coöperation for this purpose. There was in sychiatry a great tendency for treatment to be ampered by stock diagnoses. Neurosyphilis could asily be diagnosed, but there was a definite proportion f cases which could not certainly be labelled as general aralysis. If—as the discussion had suggested—here was no such pathological entity as general aralysis, then much less was there any such clinical ntity. Could we not take our stand solely on the oncept of neurosyphilis, asking: Is this patient ikely to be improved by drug treatment alone, and, f not, proceed to other forms of therapy, including nduced pyrexia. Practical application of this oncept of neurosyphilis did not exist in mental ospitals.

Dr. W. D. NICOL said that advanced cases should lso be given the benefit of treatment. Obese patients eacted badly to malaria. A small dose of quinine—.g., grs. 5 by the mouth—during treatment was one f the most important factors in lowering the death-ate. It caused a remission of 14–18 days during which he patient recovered from the strain and then started is malaria again with less severe rigors. Failure of he temperature to reach normal was a warning that omething was going wrong. Mosquitoes had been ised exclusively at Horton, and cases tended to elapse six or seven months after the febrile attack. The fact that mosquito results were 10 per cent. better han blood cases was perhaps due to this relapse, ndicating some continuous process. Experiments vere being made with a quartan strain which gave ess severe rigors and a two-day rest interval. Patients olerated quartan fever very well, and Kirschbaum in Hamburg had reported 50 per cent. of remissions from ts use. It would be useful for patients who did not mprove with benign tertian or would not reinfect vith it. About half the manic, one-third of the lepressed, and 12 per cent. of the grandiose patients vould have remissions.

Dr. KUBIE (New York) emphasised the difficulty f selecting true cases of general paralysis out of ll those in which the nervous system was involved. Even with positive serology a certain diagnosis could ot be made in the absence of intellectual defect. Those who had mental defect must be divided into the lelirious and the progressively deteriorating non-lelirious. The state of the former was not always a lorid hallucinatory delirium; there were all gradations etween that and the slow type. True deterioration vas only reached as the result of a long, slow, rogressive cortical destruction, but many neuro-yphilitics who were not paretics, as well as many aretics who were not degenerated, would show elirious episodes in which the signs of deterioration vere closely simulated. The action of the arsenicals vas a mystery, seeing that they were almost non-iffusible substances put into the blood stream, which vas binding them to its proteins and getting rid of hem in every possible way all the time. By the ime an injection was finished a great deal of the dose ad already left the blood stream. Their undoubted iological value was a pure empiricism; it was just s logical to use plain serum as salvarsanised.

Replies.

Dr. STODDART, summarising the discussion, said hat of all the treatments devised for general paralysis alaria had the best record. There was also a onsensus of opinion that some reinforcement was necessary. There might be rather more erroneous diagnosis than was usually recognised, due perhaps to attaching too much importance to serological tests. He suggested the use of malarial therapy followed by hexamine, and withdrew his statement that intracisternal puncture was dangerous and unsatisfactory.

Sir JAMES PURVES-STEWART spoke of the extraordinary unanimity that had been shown on the value of pyrexial treatment, and of malaria in particular. Diagnosis must be based on clinical and serological grounds and on neither alone. The extent of recovery possible in any individual case did not depend on the treatment, but on the amount of anatomical survival of brain structures at the commencement of the treatment. The patient must be treated before degeneration had set in.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

AT a meeting of this Section on Feb. 15th, Dr. J. S. FAIRBAIRN, the President, being in the chair, Prof. JAMES HEYMAN (Stockholm) read a paper on

EXPERIENCES OF RADIOLOGICAL TREATMENT IN GYNÆCOLOGY.

Cancer of the uterus, he said, belonged to the category of carcinomata that could be cured—i.e., for five years or more—by radiotherapy. The treatment brought about a healing process characterised by selective destruction of the tumour cells and plastic regeneration of the tissues. In most cases a moderate atrophy of the uterus and vagina remained. Failure to cure might result from many factors—too large or too small doses, unsuitable intervals, unsuitable filtration, or inferior technique. Unskilful treatment might cause severe damage and suffering to the patient, including necrosis, sloughing, and fistulæ, and the effects—good or ill—of radium only became apparent after a long latent period, perhaps of several years. The early workers had not known how to avoid the dangers, and the damage they had inflicted had done much to discredit radiotherapy. Thanks to the wise and cautious pioneer work of G. Forssell, Sweden had been particularly fortunate. Forssell had at first treated only inoperable tumours, but when undoubted results had been obtained and the technique established, he had begun with borderline cases, and had finally gone on to operable cases, when the radiological results had proved as satisfactory as the surgical. Very few operations for extensive cancer of the cervix were now performed in Sweden. Nevertheless, between 1914 and 1923 the inoperable and borderline cases treated had been 74·5 per cent. of the total, and it was almost entirely on the inoperable case that the Stockholm technique had been elaborated. Several patients treated during 1914 and 1915 were still alive.

Cancer of the Cervix.

Between 1914 and 1923 Radiumhemmet had treated 737 cases of carcinoma of the cervix, this series including every case, even those who had only had a single palliative application or who had interrupted their treatment before it was finished, but excluding prophylactic treatments before operation. All the patients had been under observation for at least five years, and the diagnosis had been histological in almost every case. Every patient had been followed up, and the Government had paid the travelling expenses of poor persons to Radiumhemmet. Of the 737 patients, 170 were alive and well five years after treatment—i.e., 23·1 per cent. Deducting cases subsequently operated on and adding some which had been too hopeless for treatment, the net five-year cure figure for all cases came to 20·6 per cent. There had been a primary mortality of 2·1 per cent. Of the 188 operable cases treated, 76, or 40·4 per cent., had been cured for five years. The figure for inoperable and borderline cases was 16 per cent., or 13 per cent. for inoperable cases alone.

The radium salt was enclosed in Dominici tubes and special applicators of many different shapes and sizes. The governing principle of treatment was a

small number of relatively heavy doses in a relatively short time, adjusted with reference to the reaction of the patient. Three applications were given in a month, with intervals of one week between the first and second, and of two weeks between the second and third. Each application lasted from 19 to 23 hours and was given through a 3 mm. lead filter within the uterus, as well as in the vagina, if possible. Every effort was made to cover the whole surface of the tumour and to get as close as possible to the pelvic walls by expanding the vagina laterally. The application varied considerably in different cases, the applicators and tubes being selected in accordance with the size and appearance of the tumour and the general condition and complications. The method was certainly simpler than a Wertheim's operation, but called for far more than mere possession of radium and theoretical knowledge. An inexperienced operator had brought down the percentage of cures at Radiumhemmet in 1916–17, and reports from different clinics varied considerably for similar reasons. Intubation of radium needles had been introduced recently, and attempts had been made to concentrate the treatment into two applications. In 1919–22 a combined treatment of radium and X rays had been tried, and this seemed to be of value in certain cases. Percutaneous treatment at a distance had shown remarkable primary results but required at least 2 g. of radium.

Cancer of the Body of the Uterus.

Forty-six cases of cancer of the body had been treated between 1913 and 1921; the 54·3 per cent. of these which had been operable were divisible into the clinically operable and the technically operable. The latter included cases where operation was unsuitable on account of complications in other organs, old age, or adiposity; they accounted for 34·8 per cent. The five-year result for all cases was 43·5 per cent. cured, and for the operable cases 60 per cent. Owing to the difficulty of obtaining microscopical diagnosis in these body cancers the figures might prove less accurate than those for the cervix. The technique was much the same as that for cancer of the cervix, but the vaginal dose was limited to two-thirds of that usually given for cervical carcinoma—i.e., about 3000 mg. e. hrs. The patient should be operated on if, two months after radium treatment, she still had discharge or hæmorrhage, or if signs of recurrence, such as pyometra, appeared later. Local radium treatment could be repeated if operation were impossible, apparently with less risk than that attending repeated vaginal treatments.

Carcinoma of the Ovaries.

The ovarian series was small and classification difficult, so that statistics of value could not be prepared. Radiological treatment alone would not yield lasting results; it must be combined with surgery. An inoperable case was first treated by X rays, the abdomen being divided into fields of about 10 by 10 cm. The dose and intervals had to be carefully adjusted to the general condition, and a leucopenia or a relative lymphopenia was an indication for decreasing the dose or increasing the interval. The initial dose was usually one-tenth or one-eighth of a skin erythema dose on one of the fields with a 0·5 mm. copper filter and 40–50 cm. skin focus distance. If all went well the dose was slowly increased to a sixth, a quarter, and a third, until a total quantity of about one skin erythema dose had been given to each field. If the tumour became small and movable, operation was performed about four weeks after the last treatment, when the effect of radiation was at a maximum. After operation X rays were continued and radium was applied as well, usually one intra-uterine application for 30 hours—about 1500 mg. e. hrs. Often it was wise to be content with palliative doses only, as attempts to remove the growth caused a worse general condition than before. Prophylactic treatment consisted in one intra-uterine radium application and a series of X ray treatments from one posterior and two anterior fields.

The conclusion was that radium alone was satisfactory in cancer of the cervix, but not elsewhere. Carcinoma of the vulva required combined treatment with electro-endothermy, X rays, and radium, local and distant. Myomata were treated almost entirely by X rays. It was of the utmost importance that treatment of gynæcological cases should be in the hands of a gynæcologist trained in radiology, who should have at his disposal an independent department equipped with every technical resource, specially trained assistants, and a follow-up organisation. The results obtained at Radiumhemmet were to be ascribed above all to the fact that the treatment of gynæcological cases had been attached to a radiotherapeutic clinic.

The Technique Used at St. Bartholomew's Hospital.

Dr. MALCOLM DONALDSON described the development of radiotherapy at St. Bartholomew's, and said that improved results had been obtained by using smaller quantities of radium for a longer time. In carcinoma of the vulva, for instance, 10 mg. in a dozen or more needles spread over 25 sq. cm. for three weeks had given the best results. Needles were used instead of plaque applicators because they gave a more uniform irradiation. The statistics from the small series so far treated were not as good as those from Stockholm, but the method had not yet been adequately tested.

The patient's vagina and cervix were cleaned up by douches for a few days, and under the anæsthetic was swabbed with picric acid. In every case a small piece of growth was removed for microscopy, and 50 mg. of radium inserted. Sixteen small needles each containing 2 mg. and with an active length of 3·2 cm., were placed around and sometimes in the growth, and six larger ones, containing 3 mg. each and with an active length of 4·8 cm., were put in the fornices to radiate upwards and outwards into the base of the broad ligaments. The vagina was then packed with gauze soaked in 1/4000 flavine and left for 144 hours. The cervix and vagina practically always healed in six or eight weeks, but late results were less satisfactory. The total dose seemed to have little to do with survival-rate, but the time factor was very important in the more resistant growths, though less so in the quickly growing ones. A number of other factors might be important but had not yet been investigated; these included the type of cell, the splitting of the dose, and the possibility of greater radio-resistance in the depths of the tumour and of "cancer-resistance" in the patient. Probably the most important factor was the advancing edge of the growth, which was very difficult to destroy entirely. This might be attacked by X rays or by intra-abdominal radium. Investigations were being made into the effect of inserting needles through the parietal peritoneum all round the pelvis at intervals of 1·5 cm., leaving them sutured to the peritoneum for a week. Fourteen cases had been thus treated. Happily the day for convincing people that radiotherapy had value was now past, and discussion centred only on the best method of applying it. The St. Bartholomew's technique was shaped with the idea of finding out the principle underlying the vulnerability of the individual cell and of applying that principle to the advancing edge of the growth.

The Use of X Rays, with or without Radium.

Dr. P. I. LEVITT described the application of X rays and of X rays plus radium to carcinoma of the cervix. Of cases treated between 1924 and 1927 with X rays alone only one was alive, but of eight treated by the combined method three were alive and well, while five out of six treated for cancer of the body of the uterus were alive, four without recurrence. Recurrences after radium were exceptional and were peripheral, just outside the zone of power; perhaps they would be less frequent if the radium were preceded by X rays. An interval of six weeks was left between the X ray and the radium to allow of maximum shrinkage of the tumour.

Neither radium nor X rays could replace the other, but they were admirably suited for combination.

Mr. COMYNS BERKELEY asked a number of questions (see Prof. Heyman's reply) and exhibited a diagram and photograph prepared by Dr. Russ to show the area irradiated by intra-uterine and vaginal applications of radium, and suggesting that it was a mistake to use two tubes in the uterine applicator.

Mr. VICTOR BONNEY spoke of the enormous difference of opinion on what was "operable," and questioned Prof. Heyman's classification of inoperability in many cases. It was impossible to tell per vaginam whether glands and thickenings were malignant or not. The standard of operability in a radiological clinic was far lower than in a surgical one. He himself had operated on 63 per cent. of all the cases he had seen. Radiologists usually failed to state their radiation-rate, leaving it to be assumed that they irradiated every case. He asked the effect of radium on the regional glands, which were carcinomatous in 40 per cent. of cases. The radiologist was running the surgeon very close but had not caught him up yet.

Mr. HERBERT SPENCER said he had used radium for 12 years—long enough to regret some of the Wertheims he had previously performed. He asked Prof. Heyman how he protected the rectum, and mentioned two patients with cancer of the body and secondaries in the vulva and vagina, who had been treated by hysterectomy, X rays, and radium and were well ten years later.

Mr. STANLEY DODD described results in 75 inoperable cases treated with radium in the last four or five years. The greatest success had been attained with a small initial dose, increased after an interval, and the spreading epitheliomatous type reacted better than the hard crateriform intracervical growths. The cervix had been needled with 30–45 mg. for a week, and three weeks later the glands had been removed from the abdomen and radium applied inside if necessary. Irremovable glands could be treated by needling or by tying in a catheter through a stab wound.

Mr. SIDNEY FORSDIKE asked if radium in the vagina would affect iliac glands.

Dr. V. B. GREEN-ARMYTAGE described a recent tour on the Continent. In Berlin pan-hysterectomies were still performed, and they would have nothing to do with radium and X rays, but elsewhere Wertheims had been abandoned and the Stockholm technique was followed.

Prof. Heyman's Reply.

Prof. HEYMAN, in reply to Mr. Comyns Berkeley, said that combined treatment with X rays and radium had been started in 1919 and abandoned in 1922 because the results had not seemed good, but a longer series was wanted, and another had been started. An X ray application between two doses of radium seemed to give better results. The main difference between the Paris technique and the Stockholm was that the Parisian workers gave a concentrated treatment for five days, whereas Stockholm gave three applications in a month. Their total dose could not be compared with his, but the results came very near. Paris and Stockholm were the only clinics that used heavy filtration. The use of 3 mm. of lead was quite empirical, but because all their dosage was calculated on that thickness of filter and the results were satisfactory they continued to use it. The 1916–17 results were inferior, because in those years more patients had been admitted than could be dealt with properly and too small doses had been given. There was nothing more dangerous than to take bits off a tumour during radiological treatment; for that reason the tumour mass was never removed manually, and it disappeared quite as well without this aid. He did not agree with the Parisian classification of tumours into endo- and ecto-cervical or with the view that the former could not be treated radiologically. He had tried taking a plastic (or dental wax) impression of the tumour and embedding the needles in it, but found that by the time two lead sheets had been placed between the mass and the growth he might as well have applicators; also the upper part of the mass was almost too large to get in and out of the vagina. Radiology was a specialty of its own, and the question of specialisation was most important. It should have its own clinic, and every representative of other specialties on its staff should be radiologically trained—which in Sweden meant three years' special work.

Replying to other questions, Prof. Heyman said he did not remove the uterus because he could not approach a growth through a short, sensitive vagina. Every method had its value, and everyone must work on his own lines for five years, then observe for five years, and then begin to discuss values. He had used needles in special cases, but had found long needles come dangerously close to big vessels and ureters. He did not agree that local recurrence was rare after radium. The only way to compare statistics was to give figures of absolute—i.e., five-year—cure. The rectum was protected by the dose, the filter, the applicator, and the method of application, and also by plugging the posterior part of the vagina well with gauze to ensure proper distance between radium and rectum. In a series of 200 cases he had seemed to get the same result with two applications as with three, but he could not recommend this until he had observed a much greater number.

SECTION OF BALNEOLOGY.

AT a meeting of this Section held on Feb. 14th, Dr. KERR PRINGLE, the President, took the chair, and a discussion was opened by Dr. R. G. GORDON on

OSTEO-ARTHRITIS.

The condition, he said, was not a clear clinical entity; it had no clear pathology which was known; in fact, there was little that was clear about it. It should mean an inflammation of the bones and joints, and this, he submitted, was a misnomer. The conditions classed under this title were not directly the results of inflammation, but were degenerative processes. The primary process was a wasting of bone-tissue, followed by a secondary attempt at repair of the destruction by throwing out new bone of irregular structure. There might be two factors, acting reciprocally—namely, damage to the joint, and inadequate blood- or lymph-supply. Osteo-arthritic changes tended to start at the central part of the cartilage, which was the least nourished part of the joint; often patients were able to give a history of injury or strain. Hip-joint disease was common among hunting men who were often in the saddle. A very small proportion of hips the seat of this condition appeared to have been the sites of any congenital abnormality. Coxa plana in the child caused very few symptoms. Thirty-four out of 100 cases showed an architecture of the joint suggestive of old and mild coxa plana. Conditions of defective structure in the child might well form the basis in later life of osteo-arthritis in that joint following strain. Flat-foot was another of the effects of strain. And it was found that bones bearing a large proportional weight showed lines of stress, as in blacksmiths' elbows and miners' shoulders. In the attempts at repair, Nature threw out more bone than was actually required; hence osteophytic outgrowths and increased density of bones. The villous arthritis which accompanied the changes met with in middle life, dependent on metabolic changes, led to osteo-arthritis if the process was not arrested. Pain was a very valuable symptom, but the extent of changes sometimes revealed by X rays, when but little pain was complained of, was surprising. The cartilaginous covering of joints was more sensitive to pain than were bony structures, but there was a relationship between the nutrition, the pain, and the sensitiveness of the joint. Charcot's joint in tabes and syringomyelia he looked upon as osteo-arthritis occurring in an insensitive joint—one which had been progressively disorganised by excessive exercise.

Treatment must be directed to preventing strain and to improving the nutrition of the joint. For avoiding strain well-fitting splints were most useful, as, for instance, the calliper splint. If infection was not the direct cause of osteo-arthritis, it could not be expected that the removal of septic foci or the administration of vaccines would have the same influence as in conditions owning infection as a cause, though for a time vaccines might result in an improvement of the general health. Many sufferers from osteo-arthritis could not stand the rigors of protein shock. Thyroid extract improved the general circulation and so indirectly affected the joint processes for the better. The hot douche was useful, but the current must be of the right strength, a strong current irritating the joint. He strongly favoured diathermy. Massage should be applied to neighbouring muscles, rather than to the affected joint. With regard to surgery, it must be remembered that the condition of these patients rendered them unable to stand severe operations. Arthrodesis and osteotomy seemed to be the only operations which were serviceable.

Discussion.

Dr. J. A. THOMSON said that often the radioscopic picture in osteo-arthritis was more an indication of the patient's resistance than of the disease itself. The level which radiology had now reached entitled it to a place in laboratory study concerning the origins and course of disease processes. He displayed on the screen a large number of radiographs of different joint conditions, and interpreted them. Incidentally he said that the presence of osteophytic growths in women was quite rare; he had seen only two cases.

Prof. TOM HARE and Dr. HENRY COHEN contributed a paper on the chemical estimation of synovial fluid and blood serum of horses affected with chronic arthritis. The investigation had been undertaken to ascertain the ætiology and pathogeny of equine chronic arthritis. The synovial fluid from an affected joint in each of 11 horses, and of the tendon sheath fluid of two bones, were chemically examined, also the blood serum of four of them. As controls they took five healthy horses of similar age and breed. The methods of procedure were minutely detailed. The conclusions arrived at were as follow: The synovial fluid and blood serum of the arthritics showed slightly lower chloride values than the normal. The phosphates, non-protein nitrogen, glucose, calcium, and uric acid of the synovial fluid and blood did not markedly depart from the normal. Excepting in one case the chloride values were higher for synovial fluid than for blood serum, in both arthritic and normal horses. Tendon sheath fluid seemed to have a constitution similar to that of synovial fluid of joints. Dr. Cohen elaborated the subject from the clinical side on the basis of his own experience. He drew special attention to the significance of early rigidity of the joint as an indication that something was wrong.

Dr. G. E. VILVANDRÉ claimed that osteo-arthritis was a definite entity, and it could not be expected that radiographs would infallibly reveal its early stages.

Dr. P. FIGDOR agreed as to the importance of trauma in these cases; in fact, he considered that osteo-arthritis was always a traumatic condition, and must be regarded and treated as a local condition, just as fracture. In osteo-arthritis of the shoulder-joint his cases had had pain two or three months before the onset of the bone condition, but this pain was below, not in the joint. In the hip-joint the pain was located in the thigh and remained the prime symptom throughout the disease. He had always treated his cases with diathermy; it was the only form of electrical current which the administrator could direct and control.

Dr. J. F. BRAILSFORD said that radiograms of most cases of osteo-arthritis of the hip-joint showed no evidence that coxa plana or congenital dislocation had existed previously. That osteo-arthritis did occur, probably in greater frequency in such hip-joints, as in other abnormal joints, was most likely due to the increased and abnormal strain to which they were subjected owing to the deformity. It had been stated that radiography was not of much importance in the diagnosis of this condition, since, when changes were visible, the disease had advanced so far that little improvement was possible. But the changes shown in the radiogram were typical of the condition and therefore most valuable in differential diagnosis. Patients were often seen who complained of pain in a joint or joints sometimes commencing without any definite injury, though as a rule a history of excessive and strained movements could be obtained. The radiogram of the painful joint showed no abnormal change, but a hidden focus of infection was often discovered, and in the case of dental sepsis, if the tooth from which the absorption was taking place was extracted, the painful condition of the joint cleared in a phenomenal manner, even though it had failed to respond to other measures. Dr. Brailsford was inclined to believe that this was the earliest sign of osteo-arthritis and that if this stage was missed insidious destructive changes took place in the joint. Often the patient experienced long periods of comfort between bouts of pain and it was probably on this account that he failed to subject himself to active treatment. It was only when there was limitation of movement and marked osteo-arthritic changes that they first appeared for radiographic examination.

Dr. C. W. BUCKLEY said the time for treatment of osteo-arthritis of the hip was before the radiogram showed anything abnormal there at all.

Mr. B. WHITCHURCH HOWELL thought that the cause of osteo-arthritis was always traumatic, occurring generally in the middle-aged or the elderly; unfortunately it was not presented for treatment until the disease condition had become well established. If only cases could be brought under treatment at an earlier stage, much more could be done for them than at present. The earliest sign of osteo-arthritis of the hip was trauma followed by synovitis of that joint; but at this stage the patient regarded it as trivial, and did not seek proper advice. Osteo-arthritis of the shoulder he regarded as very prevalent, though often overlooked. The orthopædic surgeon should insist on fixing the arm well above the patient's head, so that a free range of movement would result; if itwas strapped to the body the result would be unsatisfactory.

The PRESIDENT expressed his disagreement from those who maintained that osteo-arthritis was a local disease; he held strongly that it was a general disease with local manifestations. If a person with a traumatic injury to one hip were examined generally it would be found that the skiagram showed changes in the hip complained of, and that the other hip also gave indications of the same disease, though it had sustained no injury. He had a word of criticism as to the quality of the radiograms brought by patients; often a fresh set had to be taken, not only to see the extent of the damage, but also to prove to the patient that disease was present in the joint.

Dr. AGNES SAVILL spoke highly of the value of diathermy in joint conditions. It not only raised the body temperature in a general way, but also stimulated the various important secretions. Patients submitted to this treatment always spoke gratefully of the feeling of well-being it produced. To some of her arthritic cases she had given every kind of endocrine, auto-intoxication, and vaccine treatment, with little effect; but they had soon begun to improve on diathermy.

Reply.

Dr. GORDON, in reply, said he agreed with Dr. Cohen that the clinical signs must not be neglected. Stiffness of joints could not be looked upon as a sign of osteo-arthritis; there were many stiff joints in which the more grave condition did not supervene. He hoped the Section would not conclude from what had been said in its favour that diathermy was *the* treatment for osteo-arthritis, though he agreed it was a valuable adjuvant. In treating osteo-arthritis one must deal with the patient as a whole. He was in full agreement with Mr. Whitchurch Howell's remarks, especially as to the posture in which the arm must be placed for osteo-arthritis of the shoulder.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

At a meeting of this Society on Feb. 15th the chair as taken by Dr. J. HOWARD-JONES, the President, nd a discussion on the

CONTROL OF SMALL-POX

as opened by Dr. A. F. CAMERON. He said he referred the word "prevention" to "control" ecause the latter had no ideal before it and the whole bject of the medical officer was to prevent the spread f disease from a focus of infection. If he prevented econdary cases he had done all that could be asked f him. The present discussion might be said to ndicate an uncomfortable feeling that our methods ere not to be relied on and that their failure lay the system of control as laid down in public health gislation. The law gave to medical officers of ealth power to acquire information, to segregate fectious patients, and to carry out disinfection. he schedule of diseases for which this power was iven illustrated the lack of elasticity in the law and as one of the causes of the trouble with existing nall-pox. The Acts had come into force in 1889 nd 1891, when it was believed that destruction of ne materies morbi was essential to stop the spread f infection. The method by which the process of fection was naturally brought to an end had not nen been understood. Disinfection was the funda- nental principle upon which the law was based, nd in treatment the greatest attention was paid o the locale of the disease in order to kill the organism. f the poison could not be killed because it was idden in a living individual, that individual was egregated in hospital until the disease was at an nd. Knowledge had progressed but the law emained. Failure of secondary cases to appear as due to a pre-existing immunity in those who ame into contact with the patient. In hospital zone of control was set up around the patient, and this zone the immunised workers carried out isinfection. The two factors in segregation were, nerefore, disinfection and immunity, of which the tter was the variable factor. The efficiency of egregation varied proportionately with the degree f immunity in the zone of control. This might be atural or artificially produced. If the latter were vailable, perfect immunity in the zone of control ould be guaranteed, and for this reason segregation ust be more effective in small-pox than in scarlet ver or other diseases against which certain immunity ould not be produced artificially. In effect, therefore, egregation was only effective as a preventive of read when immunity could be guaranteed—i.e., hen spread could be prevented without it. The inimum degree of immunity required to prevent ne spread of infection was immunity of contacts, nd this could be guaranteed to prevent spread nly if it had been secured before the advent of fection. Removal to hospital was only useful if ne temporary respite from spread thus obtained were tively used to build up a zone of control.

The legal preventive measures were fundamentally fective and out of date, and there was little hope improvement until the law definitely recognised at immunity of those in contact with the focus infection was the primary factor in the prevention spread. It was a disadvantage that immunisation gainst small-pox depended on a living virus which d a pathology of its own. The people of the untry must, however, choose between continued ccination—until the bacteriologists produced a tter immunity method—and having small-pox as e of our commonest diseases. The single-insertion ccination had no advantages except that parents ight accept it more readily for infants, and its otective power was quite unknown; it reduced the ance of a take by 50 per cent. The mild disease evalent in this country now was indistinguishable, clinically and experimentally, from the more severe type, so that the name given to it did not matter and it must be dealt with administratively as small-pox. If compulsory power were applied to the immunisation of contacts the vicious circle would be broken. The mild type of small-pox had bred true for ten years and was of very little importance to the patient or the public health, but had been converted into a dangerous disease by a defective law. Its one important feature was its detrimental effect on trade and commerce, but that was a matter for business men and trade conferences to discuss. Doctors could show them how to prevent the disease if they thought it worth while; otherwise it was of no more importance than chicken-pox or rubella.

Small-pox and Small-pox Administration at the Present Time.

Dr. G. F. BUCHAN reviewed the history of small-pox in this country. Associated with the prevalence of mild small-pox since 1919 there had been smaller outbreaks of the classical variety. Mild outbreaks had been observed from early times, and variations in virulence were a constant feature of most epidemic diseases—e.g., influenza and scarlet fever. Animal experimentation seemed to prove that the virus of mild small-pox was identical with that of the severe disease. Arguments in favour of identity were: the same period of incubation, the same characteristic prodromal symptoms; the appearance of eruption at the same time, and its typical appearance. In this country, however, the prodromal symptoms in the mild form might be so trivial as to be overlooked even by the skilled observer, and the eruption did not conform to the classic description in its form of development. It was not yet known whether one type could give rise to the other or not. The Willesden outbreak did not support the hypothesis that the mild form could become the classical, because it was quite common in all diseases for an epidemic to start from one very mild case. The most important evidence was that of R. P. Garrow, who had stated that mild small-pox did not confer immunity against vaccinia for more than 8 to 12 months. This, however, did not establish the view that the two were different diseases, but rather that one was a variant of the other.

Present administrative measures included early diagnosis, removal to hospital, disinfection of premises, inquiries as to source of infection, prompt search for, and surveillance of, contacts, and vaccination. The "missed case" was undoubtedly the chief factor in the spread of small-pox, and facilities for skilled diagnosis were most important. There ought to be enough hospital accommodation for isolation of the early cases with a view to checking an epidemic. When the disease had got a hold there was reason to doubt whether hospitalisation was worth while for the mild form. No reliance could be placed on disinfection of premises, which might well be abolished for all infectious illness. Inquiry as to the source of infection was very valuable but by no means always successful. All contacts should be regi tered and visited daily for 16 days. Small-pox was not infectious before the rash appeared, and sufferers from prodromal symptoms should be isolated as suspects. Vaccination within three days of infection would prevent or modify an attack; the importance of finding and vaccinating contacts immediately could not be overestimated. Vaccination had hitherto been exploited as the lesser of two evils, but the prevailing type of small-pox was so mild that vaccination caused more absence from work than the disease. Headache and pain in the left abdomen, neck, and axilla were common after vaccination, and a few deaths from it occurred every year, apart from the occasional encephalitis associated with although probably not entirely caused by it. Nowadays small-pox caused fewer deaths than mumps or chicken-pox and, under all the circumstances, the recommendations of the Vaccination Committee were the only reasonable line to take. They advocated

three insertions, one in infancy, one between the ages of 5 and 7, and one on leaving school, instead of the usual four insertions in infancy.

Dr. A. E. BRINDLEY urged the necessity for power to obtain knowledge of intimate contacts; an astounding amount of prevarication was encountered, and the mischief was usually done before the case was seen. In Derby there had been 2008 cases of small-pox without death or marked disfigurement. Some cases had no eruption and others had a rash which no one could have recognised as small-pox if the case had not been a known contact. It should be an offence to give false information to the health authority. Power to obtain information was held by port sanitary authorities, and had been recommended by several conferences on small-pox. If the medical officer of health knew his contacts he had the reins in his hands. The statutory four insertions deterred people from submitting to vaccination. Small rural authorities could not possibly deal with this disease, and their areas formed reservoirs of infection. County councils should be made the responsible authority.

The Case against Hospitalisation and Vaccination.

Dr. R. P. GARROW argued that the reason for the discussion was that under the name of small-pox there were to-day two diseases which were quite different from the point of view of control. Their exact biological relationship was a matter of academic importance only. What were all diseases from the evolutionary aspect but fixed variants? If mild small-pox remained mild small-pox, surely it could be given a definite name, and until it was given a name it could not be treated differently from classical small-pox. A disease sui generis was one that gave rise to itself and to nothing else. "Influenza" was a name given to an infinite variety of diseases, and practically every case of mild small-pox had been labelled "influenza" in its first few days. The most important measure for mild small-pox was to give up hospitalisation. People realised that three weeks in hospital was "worth it," and refused vaccination for that reason.

Dr. R. W. JAMESON said that the recommendations of the Committee meant the immediate vaccination of 30 million people, and the further vaccination of five million annually, which was manifestly absurd. Non-epidemic vaccination was ridiculous and created antivaccinationists. Vaccination in infancy did not last a lifetime. Vaccination involved a 1/40,000 risk of encephalitis, erysipelas, and other complications, while mild small-pox involved no danger and little discomfort. We had no right to vaccinate against variola minor. Contacts had every chance of vaccination if severe small-pox arose. The public recognised the difference between the two diseases and would not object to vaccination in a grave epidemic.

Dr. J. T. NASH said that patients with mild small-pox would choose hospital instead of vaccination every time. He hoped the Society would seriously consider whether vaccination was justifiable when it was often worse than the disease against which it protected. He had noticed that the eruption of variola minor sometimes matured very rapidly, especially in old people, so that after 16 hours the pustules looked four days' old.

Dr. R. M. PICKEN said that it would be scientifically unsound to describe the two forms by different names, although undoubtedly they were administratively quite different. He knew no other two diseases against which immunity could be produced by the same procedure and which immunised against one another. Many cases of the most virulent type might be missed because there was no eruption, and mild missed cases might occur amongst the unvaccinated as well as the vaccinated. Universal vaccination must be advocated for classical small-pox, and the procedure must be modified for the present type. The public were quite intelligent enough to appreciate this. There was something to be said for abandoning hospitalisation, but this mild disease had at any rate provided a valuable opportunity for making local authorities bring their hospitals up to standard. When classical small-pox came again—as it undoubtedly would—we should be better able to deal with it as a result of this mild type.

The PRESIDENT spoke in favour of vaccination of contacts and isolation of cases, and said that the method of vaccination should be improved.

Dr. CAMERON and Dr. BUCHAN briefly replied.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held at the B.M.A. House on Jan. 22nd, Miss F. HUXLEY, the President, being in the chair.

A paper was read by Dr. DOROTHY DOUGLAS on the working of the

Mackenzie Institute of Clinical Research at St. Andrew's.

After outlining briefly the foundation of the Institute, and commenting on the life and work of its great originator, Dr. Douglas went on to explain the aims of the organisation. These were, principally: (1) to obtain a large series of accurate life-histories of the health of individuals, whose circumstances, habits, and, if possible, antecedents were known; and (2) by an intensive and minute study of cases of disease, especially in its early stages, to arrive at a better knowledge of the meaning of symptoms, as opposed to physical signs.

Disease states might be divided into two groups: first, those in which there are symptoms only, without physical signs, and therefore only disorder of function; and secondly, those in which physical signs could be elicted, and therefore structural change might be postulated. It was always Mackenzie's aim, by an early recognition of the first group, to prevent the occurrence of the second. St. Andrew's was chosen as the site for such a research, chiefly because it is a very small and somewhat remote town. This makes it comparatively easy to follow up patients and to discover facts about their families and circumstances; moreover, it is there possible to keep in touch with individuals over a large number of years, since the population is more or less stationary. For much the same reasons it was decided to staff the Institute entirely from general practitioners of the town, since they would naturally be the first to see the earliest symptoms of disorder. At the present time it was found practicable to employ in addition a full-time pathologist and bacteriologist, a radiologist, and a pediatrist. The services of the general practitioners were entirely voluntary, and the general feeling locally, both among the doctors and the general public, was that the work, besides being part of a most necessary research, acts as a stimulus to thought and discussion, and much increased the interest of the routine of general practice. Many important papers had been published by the Institute since its foundation, and a comprehensive mass of material in the shape of accurate clinical notes of a large number of cases of special interest had been gathered together. This material was available to investigators following out a particular symptom or disease. It was to be hoped that such unique opportunities for clinical research as were offered at the Institute would be utilised to the full.

BRISTOL EYE HOSPITAL.—The annual report shows that last year 13,116 out-patients attended, an increase of 1000 over the preceding year; there was also a substantial increase in the number of in-patients. The need of larger premises is urgent, and the number of beds needs to be doubled, but enlargement has been postponed until the whole question of the Bristol hospitals has been considered by a body which is in process of formation.

Reviews and Notices of Books.

Radium Treatment of Cancer.

By Stanford Cade, F.R.C.S. Eng., Assistant Surgeon to the Westminster Hospital. London: J. and A. Churchill. 1929. Pp. 158. 15*s*.

No time could have been more opportune than the present for the appearance of this book by Mr. Stanford Cade. Every hospital in this country is either procuring, or endeavouring to procure, a supply of radium, great or small. It is one thing to possess radium, but quite another matter to employ it scientifically and therapeutically. There is no question that this sudden popularity of the precious element is not without danger. In the hands of skilled workers radium is wonderfully useful, but in those of the amateur it is apt to be useless or worse. Much of the value of the work before us is due to its being a record of the experience of an operating surgeon, who has, after much experience, decided that in certain situations of the body cancer is as well treated by radium as by the scalpel, if not better treated. Mr. Cade reminds his readers that radium therapy is still in its infancy, and its employment demands special knowledge and special methods of technique; and he admits that what he teaches to-day may be merely of historical interest before many years or even months are passed.

After a useful chapter devoted to the various general methods by which radium salts or emanation may be applied to a tumour, and a description of the different forms of application, Mr. Cade takes in order the various lesions that he and his colleagues at the Westminster Hospital, and workers at St. Bartholomew's Hospital and the London Radium Institute, among others, have been treating for the last five years or more. He begins with cancer of the buccal cavity, and this is perhaps the most interesting and important chapter of all, since the immediate and local results procured by radium on the primary growth in this neighbourhood altogether surpass those due to surgery; but he freely admits that the problem of how best to deal with the lymphatic glands is not yet settled. The technique for radium treatment of cancer of the tongue is elaborate, and should be carefully studied by a surgeon before he undertakes the treatment of a case without previous experience. In the chapter devoted to treatment of carcinoma of the larynx, the author quotes at some length from the published writings of Mr. Douglas Harmer, who has demonstrated remarkable results in cases of intrinsic carcinoma of the larynx, after irradiation by means of a window cut in the thyroid cartilage. In two other conditions radium has proved its great value—cancer of the breast and cancer of the cervix of the uterus. In malignant disease of the rectum the results have so far been less satisfactory, and no single method of approach has yet been decided upon, although Sir Charles Gordon-Watson has achieved several remarkably good results with platinum needles, and also with radon seeds.

A prolonged excursion deep into the physics of radium is not to be expected in a text-book of this kind, but in Mr. Cade's description of the time factor he neglects to include any reference to the filter; an omission which must be a slip, since it is of paramount importance to know if platinum, gold, silver, or lead is to be used, and the thickness in millimetres in each case.

We strongly advise any surgeon who thinks of taking up the treatment of cancer by radium to read carefully this excellent text-book. An important feature is the large number of coloured plates and diagrams by which the book is profusely illustrated.

Modern Views on Digestion and Gastric Disease.

Second edition. By Hugh MacLean, M.D., D.Sc., F.R.C.P., Professor of Medicine, University of London; and Director of the Medical Clinic, St. Thomas's Hospital. London: Constable and Co., Ltd. 1928. Pp. 182. 12*s*.

The value of this book depends not so much on a wide survey of gastric physiology and pathology which its title might lead one to expect, as on the clear and concise manner in which a method of treatment, based on known facts of physiology and pathology, is set forth. The attempt at simplification has brought in its train dogmatism on some controversial topics, but, on the whole, this attitude may be justified, so great is the need for definite guidance in treatment of disorders of the intestinal tract. In this edition the views previously expressed on duodenal regurgitation as a physiological process have been abandoned; the reasons for this change of outlook are clearly given. Facts are advanced to support the theory that the stomach, besides secreting hydrochloric acid, also secretes sodium chloride, and that although there is no quantitative relationship between the hydrochloric acid and pepsin, the latter bears a very definite relationship to the amount of sodium chloride. A chapter is devoted to the fractional test-meal. Prof. MacLean fully agrees that this method is of great value in the scientific investigation of gastric disease. He still considers, however, that the deviations between normal and pathological are not sufficiently well known to render the method of very much greater value than the simpler single estimation in ordinary clinical work. The chapter on treatment confirms and emphasises the results obtained by intensive alkali therapy on the lines first advocated by Sippy, and Prof. MacLean claims that even patients suffering from pyloric stenosis are often greatly benefited by this treatment. Alkalosis is described as a very rare complication and some useful notes on its recognition and treatment are given. The excellent X ray photographs of gastric conditions supplied by Dr. Geoffrey Fildes add greatly to the value of the book.

Infant Welfare.

Infant Feeding and Nutrition. By Howard B. Gladstone, M.D. London: W. Heinemann, Ltd. 1928. Pp. 118. 7*s*. 6*d*.

In this book Dr. Gladstone presents the result of many years' experience at the Sydenham Infant Welfare Centre, in a form which gives practical guidance to practitioners in the subject of infant feeding. He does not adhere closely to any particular system, but describes a large variety of methods of feeding with fresh and dried milk, including both percentage feeding and simple dilutions, in all of which he has obtained success. A considerable part of the book is devoted to the consideration of different varieties of dried milk and proprietary foods, and their relative merits. The progress of a number of individual cases is recorded, and illustrated by feeding and weight charts. The last chapters give a brief summary of the rôle of vitamins and of heliotherapy in infant nutrition.

Sozialhygiene im Säuglings- und Kleinkindesalter. By Eugen Stransky, Vienna. Leipzig and Vienna: Franz Deuticke. 1929. Pp. 129. M.8.

In this monograph Dr. Stransky reviews the effect of social and administrative work on disease and mortality in infants and small children, as shown by statistics drawn from various parts of the world, and he gives some account of methods of which he has had experience in Austria. The most striking fact which emerges from his comparative tables is that the mortality in the new-born and the first month has remained stationary throughout the world, in contrast to the very great reduction which has taken place in the total infant mortality during the last decade. The

extent to which this neonatal mortality might be reduced by antenatal centres and obstetric institutions is discussed. The author recognises candidly that a complete abolition of infant mortality would exert a deleterious effect on natural selection, but he believes that a rate of 30 per 1000 births (contrasted with 100 in Germany and Austria) would be an adequate safeguard. The last portion of the book is devoted to children of the pre-school and early school ages, and is largely concerned with the prophylaxis of infectious disease and the assistance obtained from laboratory tests such as those of Schick and Dick. The author is convinced that under modern conditions it is essential that all children of the labouring classes shall be brought under highly organised medical control.

ETYMOLOGICAL DICTIONARY OF CHEMISTRY AND MINERALOGY.

By DOROTHY BAILEY, Sc.B., Ph.D., and KENNETH C. BAILEY, M.A., Sc.D., Fellow of Trinity College, Dublin. London: Edward Arnold and Co. 1929. Pp. 307. 25*s*.

THE aim of the compilers of this dictionary is primarily etymological. They desire to inform the reader who is curious about such things the derivation of chemical and mineralogical names. Trade names have been omitted with the exception of a few of the more important, such as aspirin, the derivation of which is set out as follows: "Aspirin, trade name for acetyl-salicylic acid. A(cetyl) and spiræic acid (old name for salicylic acid found in *Spiræa ulmaria*) Pflüger's Archiv, 1899, lxxvi., 307." Another interesting note concerns "Sklodowskite, hydrated silicate of uranium and magnesium. After Mme. Marie Curie (née Sklodowska), famous for researches on radio-active substances." As regards stovaine the authors state "Derivation not discovered; possibly from English *stove*, in jesting allusion to the name of the discoverer, Fourneau, & -aine (as in cocaine)." They have made a good guess, of which the confirmation will be found in THE LANCET (1920, i., 358). The derivation of Jade "from the Spanish *Piedra de ijada*, colic stone from the belief that it protected from nephritic colic," is curious. The word "Spelter," the commercial name by which zinc is more generally known in the metal market, might have been included. Spelter is, etymologically, curiously akin to pewter, which is not always only an alloy of tin and lead. The dictionary is certainly interesting and useful. It does not contain all the names of the minerals and synonyms which are to be found in Dr. T. Egleston's Catalogue published in 1892, but it gives entertaining notes which the catalogue omits on the etymology of some of the names.

THE WOMAN A MAN MARRIES.

By VICTOR C. PEDERSEN, M.D., A.M., F.A.C.S. London: Jarrold and Sons, Ltd. 1928. Pp. 247. 6*s*.

THE presupposition of this book is that ignorance is at the root of most evils. It contains six chapters, the titles of which are: ignorance of biology and physiology, ignorance of social development, ignorance of social conditions, ignorance of venereal disease, ignorance of marriage, and ignorance of the relief. The relief would appear to be constituted by those measures propounded by education, the law, and the Church for the solution of the problems of sex. Enlightenment on these six topics will, it is submitted, give rise to the conviction that "immorality is a nightmare in the recorded history of man," and that "monogamy as a social product and marriage as a personal contract based upon it are fundamental to the most civilised society of to-day." The method of exposition combines a presentation of the alleged basic scientific facts of sex with a narration of case-histories of marital disharmonies after the manner of Judge Ben Lindsey. The author is an American, and the book is written from an American point of view. The case-histories it contains are of American couples, and the legal solutions discussed are from American State and Federal laws. The book will chiefly be valuable to English readers who are interested in America.

THE SHADOW OF THE WORLD'S FUTURE.

By Sir GEORGE HANDLEY KNIBBS, C.M.G., F.R.A.S. London: Ernest Benn, Ltd. 1928. Pp. 131. 10*s*. 6*d*.

IN the words of its author, "this book is an exposition of the consequences of the limited population-carrying capacity, under various conditions, of our earth." Man's agricultural, forestal, and animal needs, the world's cereal and food crops and its mineral needs, and the complicated problems of international migration are dealt with from the statistical point of view in successive chapters. The conclusion reached is that in a short time the multiplying force of man will receive a tremendous check. When the shadow of over-population looms large, the world politic will be confronted with a complex problem possessing racial, economic, and moral aspects. It will have to decide whether it is better that there should be larger numbers and more modest living, or fewer numbers and lavish living; and whether world morality should aim at the enjoyment of life by a great multitude or at the restriction of life experience to a few, who may live in relative opulence. Whether the world politic will make its decision through the unconcerted action of separate individuals responding, each in his own way, to economic pressure, or by edicts emanating from a central world-state, or from different governments, the author does not venture to prophesy.

A COLONIAL YEAR BOOK.

The South and East African Year Book and Guide for 1929, with Atlas. Edited by A. SAMLER BROWN, F.R.M.S., and G. GORDON BROWN, F.R.G.S. London: Sampson Low, Marston and Co., Ltd. Pp. 912. 2*s*. 6*d*.; by post, 3*s*.

THIS volume is written simply to give information for passengers by the Union Mail Steamship Co., but it really forms an excellent history of those of the Colonial possessions which are brought into contact with the home country by the various routes of the company. It is not merely a detailed handbook to the ports of call, but it deals with the early history and subsequent developments of the countries concerned, giving an intelligible story, for example, of Cape Colony, Natal, Zululand, and the Transvaal, followed by an excellent account of the Union of South Africa and of Southern Rhodesia, formerly the British South African Company's territory. East Africa is treated with similar fullness, Kenya Colony, Uganda, Tanganyika, and the adjoining territories being described. Throughout we have notes upon climate, agricultural administration and farming, emigration, the acquisition of land, mining, and, lastly, the diseases that may be incurred, the whole being rounded off with general information as to the fauna and the sport in these vast countries. The book is sold at a low price in the hope that the act of placing such an exhaustive work at the easy disposal of the public may assist in a great migration movement within the British Empire, with the view that such a movement is a vital necessity at the present time. It contains nearly a thousand pages with plans and diagrams, and a specially prepared atlas of 64 pages and maps in colour.

THE book on "William Harvey," by Archibald Malloch, reviewed in THE LANCET of Jan. 19th, is now published in this country by Mr. Humphrey Milford (Oxford University Press) at 7*s*. 6*d*.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 23, 1929.

EXPOSURE TO COLD.

ARCTIC conditions in the temperate zone of Europe during the past fortnight have led to an unwilling study of the effect upon the human body of exposure to cold. This effect is popularly supposed to be a primary one of stimulation to metabolism and to the nervous output of energy, followed, as the exposure is prolonged and increases in severity, by a reaction in which the general functions of the body become depressed and the liability to disease processes, especially of an inflammatory nature, is increased. The occurrence of large numbers of cases of so-called trench-foot during the late war induced some experimental investigation of this condition, but the conclusions reached by various workers showed little agreement. Attention was mainly confined to the local lesion; hardly any reference was made to widespread effects upon the body as a whole. Most animals have resisting powers of a high order, and the general effects of cold when they occurred were attributed to secondary causes rather than to the cold itself. The first systematic inquiry into the effects of cold upon individual tissues was made by Mr. NORMAN LAKE towards the end of the war period.[1] Working with tissues growing in vitro, and thus isolated from any vascular reactionary effect, he was able to prove that there was a critical temperature in the neighbourhood of minus 6° C. (equivalent to 21° F.) below which cellular life, in all higher forms of life, was destroyed. At temperatures a little above this limit tissues could be stored for prolonged periods without showing any diminution of vitality when again thawed. Explanted portions of embryo heart, kept growing and pulsating in the incubator for two or three days, could be stored in a state of suspended animation for two to three weeks at minus 1° C. only to resume normal growth and pulsation immediately they were again raised to the appropriate temperature. The complete excised heart subjected to similar treatment began again to beat normally when thawed and perfused with nutritive fluids at the proper pressure, and this was found to be true of all tissues. Below the critical temperature mentioned protoplasm itself freezes and its intimate colloidal structure is destroyed, so that while it remains chemically unchanged the physical architecture, so essential for the continuance of vital processes, is disrupted. A somewhat similar change can be seen during the freezing of a simple substance like gelatin when, at the critical temperature, the translucent mass suddenly becomes opaque owing to the disruption of the continuous phase of the colloidal system. In this case the colloidal structure is again attained upon warming, but the change in cytoplasm is irreversible. From a theoretical consideration of the electrolyte content of cytoplasm the freezing-point would be expected to be in the region of minus 0·7° C.

LAKE subsequently showed[2] by an investigation of the freezing curves of various types of protoplasm that the discrepancy was explained by the phenomenon of super-cooling, and he was led to the conclusion that in the cytoplasmic colloidal system the more fluid phase was the disperse one—i.e., that it had the structure of a gel. The isolated droplets of this phase, protected from all external influences except the cold, invariably undergo super-cooling; once the colloidal structure has been destroyed, however, the resultant material freezes at the correct theoretical temperature of minus 0·7° C.

The essential difference in the effect of cold above and below the critical point was further proved by investigations upon animals and upon the human skin. LAKE was thus able to demonstrate a fundamental difference between true frost-bite and the effects of chilling. In the former there is direct and immediate cellular destruction; in the latter the tissues remain intact in a state of suspended animation until thawing occurs, the subsequent pathological effects being due to stasis and to the pressure of exudations, which may be so intense as to produce a secondary gangrene. The cause of the exudation is a vasomotor paralysis accompanied, it may be, by some increased capillary permeability; both of these factors are enhanced when the thawing is rapid. In LAKE'S experiments it was shown that these reactionary effects could be entirely prevented by any means which restricted the capillary flow and pressure. Thus the local use of vaso-constrictors or ligation of the main artery to the limb prevented, paradoxically enough, the onset of gangrene. The fibrinous nature of the exudate which occurs after chilling often produced lymphatic blockage, the effects of which were seen long after the vascular condition had subsided, a fact which probably explains the predisposition to further attacks. The manner in which the vasomotor changes are produced is uncertain. Section or blocking of the somatic nerves supplying the part does not prevent the onset of the condition; periarterial sympathectomy, although increasing the circulation through the normal limb, proved of no value in these experiments—a result which was to be anticipated since the resulting vaso-dilatation would only tend to increase the exudation. The vasomotor effect is probably a local one due perhaps to a temporary paresis of the musculature of the arterioles. A. E. WRIGHT and L. COLEBROOK suggested[3] that the effects were due to a local acidosis which also predisposed to infection, while other authors attributed it to local ischæmia, nervous exhaustion, and infection. Whatever the ultimate mechanism may be, it is clear that the main effects of chilling of the tissues are due to vasomotor reaction; they are thus seen chiefly and in severest form in those whose vasomotor system is unstable and characteristically in the young.

From the practical point of view it must be appreciated that the external temperature necessary to produce actual frost-bite will lie far below the critical point of minus 6° C., owing to the heat conveyed to the surface from the warmer underlying structures; for this reason frost-bite is rare in this country, although it is occasionally met with in exposed situations and in airmen who are insufficiently protected. The commonest local effect of cold is the chilblain, in which the capillary engorgement and exudation are sufficiently obvious. Until recently chilblains were rarely seen except upon the feet, hands,

[1] Report upon an Investigation into the Effects of Cold upon the Body, THE LANCET, 1917, ii., 557.

[2] Preliminary Report upon the Pathology, Prevention, and Treatment of the Condition known as Trench Foot. (Unpublished report to War Office.)

[3] On the Acidosis of Shock and Suspended Circulation, THE LANCET, 1918, i., 763.

and ears, but large chilled areas are now sometimes found on the leg, a phenomenon which possibly bears some relationship to the change from wool to silk stockings. The means of prevention which proved satisfactory in the case of trench-foot may also be applied in civil life. Of these the most important is the retention of a layer of dry air next to the skin surface by the use of a covering of non-conducting material having a fine reticulate structure. When exposure to wind is added to cold an outer layer impervious to air is essential if excessive heat loss is to be prevented. Water being a good conductor of heat, all clothing should be kept as dry as possible by adequate ventilation. The problem is one of maintaining a proper balance between the supply of heat to the part and that lost. The supply is derived from the circulating blood and the local metabolism; in sedentary occupations the latter is reduced to a minimum and in consequence the heat loss must also be reduced. The main factor in this reduction is the automatic contraction of the superficial vessels; this should therefore not be counteracted unless at the same time the circulation and metabolism of the deeper parts be increased—e.g., by exercise. Foods rich in fats and carbohydrates help to build up a readily available caloric reserve, which, through the increased tone of the muscles, supplies additional heat even when the latter are at rest. Internal administration of various remedies has been popular in the treatment and prevention of this condition from time to time, but none of them appears to be wholly successful. From a consideration of the pathology of chilling it would appear that the only logical substances to use are general vasomotor tonics which tend to produce constriction, especially of peripheral vessels. Perhaps the best example of these is strychnine. Where large areas of the body are exposed the heat-loss may be so great that the normal balance between production and loss cannot be maintained and the internal body temperature begins to fall, metabolism is diminished, and a vicious circle arises which, unless broken, ends in death. In such cases the tissues are only in a state of suspended animation, so that if the circle be broken by the artificial supply of heat to the body there is every prospect of recovery. Stories of animals frozen to death and thawed out alive are well documented, and experiment has shown that in embryos and very young animals such a state of suspended animation may exist for several hours without deleterious effects upon subsequent vitality. That such degrees of exposure when recovered from are likely to be followed by inflammatory reactions in internal organs, such as the lungs and kidneys, is common knowledge; they are due to the onset of changes similar to those in superficial structures.

The less severe degrees of exposure met with in temperate climates are adequately compensated by the thermogenetic centres so that the general body temperature does not alter appreciably. The sequelæ sometimes seen in internal structures cannot then be explained on the basis of chilling; they are possibly due to a slightly diminished resistance in the presence of a pre-existing lesion or infection, or to a reflex effect through the nervous system—e.g., the intestinal colic occurring in predisposed subjects, which gives rise to the wearing of a cholera belt. On the other hand, in the upper air passages there may be actual tissue chilling on which exudation follows. To sum up: While the local effects of exposure to cold are evident, the general effects of moderate exposure are slight—a conclusion which agrees with that reached by most investigators of trench-foot during the war.

WORKMEN'S COMPENSATION AND THE MEDICAL REFEREE.

IT may be useful to give publicity to the dicta of a judge of the Court of Appeal in Scotland on the form, and particularly the substance, of the certificates given by medical referees in the course of an arbitration under the Workmen's Compensation code. The observations were made in BROWN AND WILLIAM DIXON, LTD., reported in *Scots Law Times*, 1929, p. 109, and emanate from Lord SANDS, a sound lawyer and a man of wide sympathies and manifold interests. His lordship, after pointing out that the report of a medical referee is final, continued: "It has been found necessary in some cases to refer back to the medical referee to explain his meaning. This necessity has generally arisen from the fact that the report was not clear and unambiguous in its terms. Now, I can quite appreciate that in regard to such matters as are revealed to a medical referee, it may sometimes be difficult to form an absolutely confident opinion. But this difficulty does not justify the referee in giving a halting report. Certain definite questions are referred to the medical referee. He has got to make up his mind, and doubts and difficulties he may experience in the process should not be reflected in his report, which should be succinct, definite, and categorical." Many of our readers may be inclined to comment on those words by finding that while it is easy for the eminent lawyer to lay down for them the path of duty, members of another profession may find it practically impossible to comply with the precepts. They will recall that the questions placed before them are often obscure and open apparently to conflicting answers, and they will feel that only ignorance or self-conceit would lead a doctor to deny the possibility of varying opinions having equal probabilities of representing the truth. It should, therefore, be made clear that Lord SANDS is an eminently reasonable man, very far from desiring to dictate, or to lay impossible burdens on others.

Lord SANDS'S remarks were made in a case where the medical referee had first given one certificate and then a directly contradictory certificate; the county court judge had been accordingly misled in procedure, with the result of a successful appeal by the employers to the Court of Appeal, all leading to the piling up of law costs. Take Lord SANDS'S three requisites for a medical referee's report. It is first, to be "succinct," and that means that no reasons for his views are required from the referee. But whenever it is permissible to state a decision without giving the reasons, it is foolish to do so; it is sufficient to be able to adduce the reasons when they are asked for by those who have a right to learn them. Every decision, in whatever sphere, must be reached by a course of reasoning, in which the steps may be numerous. Possibly at every one of these stages more than one direction for the next step appears possible, and a choice has to be made, accepting one and rejecting the others. If all these are to be stated and the reasons for acceptance and rejection, the report will not be succinct, but will become a tortuous maze, the threading of which will waste time and invite error. Next, the medical referee is to be "definite." That means that he is to yea or nay, and the biblical injunction applies: "let your communication be, yea, yea; nay, nay." There is no room for the hesitating counsellor. Mr Facing-Both-ways, with his view that "black's not so black, nor white so very white," is a danger and not a help. Thirdly, the medical referee is to be

"categorical." So far as this is not a repetition of the preceding, it simply means that, if more than one question is referred, they ought to be dealt with separately, and separate answers returned, each clearly and expressly dealing with one question. It may be noted, however, that Lord SANDS employs the word "report," a little inaccuracy which would exactly condone the discursiveness which he is condemning. The Act speaks of "decisions" and "certificates." These may be contradistinguished from a report, for the latter is naturally a full and exhaustive, and it may be even a discursive, document. A report which ignored all symptoms and arguments tending to the opposite of the conclusion reached by the reporter would expose itself to adverse criticism. In face of the judicial animadversion on the form of doctors' "reports," it may be indicated that the references to the medical man are not submitted in the best form. In the case of juries it is usual to leave the issue to them in the shape of specific questions formulated by the court, and deliberately framed so as to be capable of being answered by a "Yes" or by a "No," or in some other way not really essentially different. Clearly such answers are what are desiderated by Lord SANDS, and in the same case the Lord President, Lord CLYDE, expressly said that the answer ought to have been "Yea" or "Nay." Rules and forms have been issued for the guidance of medical referees, but these have come under judicial criticism in England. Certainly they seem to proceed on the wrong lines. The idea at the back of them is that the medical referee shall use a printed form, and shall, as it were, frame a paper, which may be called a report, but the authoritative part of which shall be his decision, or certificate, or both. The better way would be that the document should reach the referee with the reference, and complete in all respects up to and including succinct, definite, and categorical statement of the questions referred, with blanks for the answers of the yea or nay order. Then, and then only, would it be altogether correct to say, in the words of Lord SANDS, that "certain definite questions are referred to the medical referee."

It occurs at once to all our minds that what is demanded of medical referees is a standard of the categorical imperative to which the judicial bench does not attain. It is not uncommon for a judge to state that in the course of the case he has altered his opinion, and that in the end it is only with great hesitation that he has arrived at his decision. And as regards discussing the arguments pro and con, that is the rule rather than the exception in judicial utterances. But really there is no comparison between the situations, and indeed in some countries judges are bound to state in detail their reasons. They are bound to follow judicial precedents even contrary to their own opinions; and usually these are not final. A medical referee is in a different position. He is not bound to follow other medical opinion, however eminent; and not subject to any right of appeal, for what he says is "final" and "conclusive." In a sense that makes his position more difficult; a judge frequently states from the bench that he hopes an appeal will be taken against his decision, while the medical referee has no such chance of confessing fallibility. Power must always carry responsibility; and the weight of that will be felt more acutely by one man than by another. But most men are conscientious, and deeply anxious "honeste vivere, alterum non lædere, suum cuique tribuere," which has been called the holiest civil wisdom. And is the issue which the medical referee has to decide in no way unique? Other men have to face greater responsibilities, and every doctor has to do so constantly in ordinary practice. No doubt in some of the latter instances he can call in a specialist, but that only shifts the burden from A to B; and in the references made to the medical referee in cases of workmen's compensation the referee *is* the specialist.

CHRONIC RHEUMATIC ARTHRITIS.

THE progress of our knowledge of chronic diseases of bones and joints has been slow and is still in process of evolution. Although arthritic changes found in fossil bones show that our remote ancestors suffered from these disabilities, we are far from having a clear notion of their pathology. The old-time physicians were vague enough as to the definition of rheumatism; but they felt that, though inflammation of one joint might be caused by trauma, inflammation of several joints should be accounted for by a "rheumatoid" state—the presence of a humour floating in the blood and causing disease. The search for the peccant humour continues and the explanation of the mechanism of its action remains hidden. Chronic arthritis being a disabling rather than a killing disease, there was seldom opportunity to observe the early changes in the joints, while in the later stages the pathological pictures were confused by the presence of degenerative changes side by side with those of long-standing inflammation. The cause and pathology being thus obscure, attention was directed to the clinical aspects of this group of diseases, and, as observations accumulated, differences appeared to suggest the possibility of division into several types. By the beginning of this century A. E. GARROD [1] had reached the position that the great bulk of the cases spoken of as examples of rheumatoid or osteo-arthritis would seem to be examples of two maladies which present distinct clinical features, both infective, but probably caused by different organisms, which he proposed to name rheumatoid arthritis and osteo-arthritis. With no sure pathological basis, these and other terms were used by different observers in different senses, new classifications were put forward which divided up the cases in different ways, and confusion reigned in the minds of students and practitioners, even (it was suspected) in the minds of learned professors themselves. In all these clinical classifications—a typical one is that proposed by NICHOLS and RICHARDSON [2] in 1909 and adopted largely in English-speaking countries—there is a tendency to distinguish broadly between the more active inflammatory course and the prolonged reactive or degenerative type. Indeed in some countries the division has been made, albeit on insufficient pathological grounds, into cases of "arthritis" and those of "arthrosis." So many tissues enter into the structure of a joint—synovial membrane, cartilage, bone, capsule, ligaments—that the response to inflammation may be very varied. As in a mountain chain the different strata are so arranged that the peaks have diverse and individual characteristics, and the traveller from the west is met by steep declivities and sheer walls quite other than the gentle decline of the spurs and foothills of the eastern side of the same mountain range; so, in the present-day view, the diversity of this group of diseases is regarded as apparent rather than real.

[1] Articles on Rheumatoid Arthritis and Osteo-arthritis in Allbutt and Rolleston's System of Medicine, Vol. III., London, 1907. [2] Jour. Med. Research, 1909, xxi., 149.

and the result of varying reaction between the intensity of infection and resistance.

It was the more chronic forms which occupied the attention of the Royal Society of Medicine last week in a discussion on osteo-arthritis (reported in another column), but the divergence of clinical views was still there. Some speakers regarded osteo-arthritis as a local condition affecting one joint only; others considered that it was a general disease with local manifestations. Dr. R. G. GORDON, who opened the discussion, alluded to the lack of a clear pathological definition of the conditions classed under this heading. He regarded them mainly as degenerative processes. He emphasised the effect of trauma, either in producing direct damage to the joint or indirectly in affecting it through strain; indeed trauma was to his mind a much greater causative factor than infection. In this connexion we recall attention to the work of LERICHE and BRENCKMANN [3] who grafted pieces of bone into the neighbourhood of animal joints. They found that the presence of dying bone appears to act as a stimulus to the production of new cartilage and bone, and they suggest that foci of necrosis in the epiphysis may provoke the outgrowths of bone and cartilage in cases of arthritis. The necrosis may be the result of embolic infection, or may be brought about by injury of the central cartilage which is the least nourished tissue of the joint. Local chemical alterations may play their part. Prof. TOM HARE and Dr. H. COHEN carried out chemical estimations of synovial fluid and blood serum of horses affected with chronic arthritis; both fluids showed lower chloride values than those of the normal horse. Further help may be expected from experimental pathology and biochemistry in clarifying the diagnosis and indicating appropriate treatment. Interest is growing. The past year has seen the inauguration of a National Campaign for Combating Rheumatic Diseases. This is a logical movement, for these diseases are of first-rate importance owing to their disabling effects on the individual and the loss incurred by industry and the community as a whole.

Annotations.

"Ne quid nimis."

THE KING.

THE only official bulletin issued during the past week speaks of slow progress and an increase in weight. The weather has been far from favourable to invalids, and Aldwick has had its share of dull days and sharp frost. There has been warm sunshine at times, however, and despite ice on the foreshore and a snow-strewn countryside, conditions at Craigweil House are certainly more stimulating than they are in London, where fogs are everyday occurrences. Though still very weak and unable to receive visits from any but his own family, the KING is now able to take ordinary food. His improvement, which is no slower than was anticipated, should gather speed as it progresses, and it is evident that a good deal of ground has been gained since His Majesty reached the South Coast.

THE SEBORRHŒIC STATE.

IT is a truism to say that the whole of our complicated nervous system is a specialised and protected piece of skin, yet, well known as this fact is, our attitude to the two ectodermal mechanisms remains completely different. For we treat our skin with contempt and our central nervous system with the utmost respect. An enormous amount of work has been done on the bacteriology of the nervous system, but relatively little on that of the epidermis. We know that the central nervous system is elaborately protected from bacterial invasion by a lymph-space, through which it is difficult for organisms to penetrate, but it is not so commonly realised that the true skin is almost as well protected by its horny layers, which are never penetrated when intact. This, as Dr. H. W. Barber pointed out in his first Lettsomian lecture, delivered before the Medical Society of London on Feb. 18th, is largely due to the presence in sweat of cholesterol fats, which are not a suitable culture medium. At this point, however, the vulnerability of the skin does become apparent. A trivial infective lesion in the brain cannot collect to itself the astonishing number of adjuvant organisms which a similar disorder of the skin invariably attracts.

The three most common of these organisms, according to Dr. Barber, are the pityrosporon of Melasseg (the "bottle bacillus"), the micro-bacillus of acne, and *Staphylococcus albus*. He calls them the "seborrhœic triad," because seborrhœa is by far the most frequent predisposing factor to their growth. The seborrhœic is perhaps the commonest diathesis known to us, and may be a valuable indicator of faulty metabolism. Dr. Barber points to it as an example of how a metabolic change resulting from unnatural conditions of life may produce an environment which enables harmless saprophytes to become parasites and produce disease. Each of the organisms has its site of election in the skin and stimulates a special type of cell response when it becomes active. The pityrosporon grows between the layers of the stratum corneum, the resulting dandruff or scurf being an attempt to cast off the parasite. In the scabrous skin it provokes definite clinical and histological signs of inflammation. The acne bacillus flourishes in the infundibular portion of the pilo-sebaceous follicles, and may promote a non-inflammatory or an inflammatory defence reaction—the comedo and the pustule. Staphylococci usually take their place at the ostium of the pilo-sebaceous follicle, and the body's normal defence to their invasion is the polymorphonuclear leucocyte.

The mild seborrhœic state, according to Dr. Barber, is so common as to be almost universal, but those in whom manifestations are severe enough to demand treatment are of two types: the flourishing, robust, active, plethoric—or "simple"—seborrhœic type and the pallid, thick-skinned, pigmented, hypotonic, toxic type. Their skin appears thickened, coarse, and dirty; the horny layer is improperly formed and hypertrophied, the pilo-sebaceous orifices are enlarged and patulous, exuding droplets or filled with solid plugs. There is often visible hyperidrosis; the scalp is greasy and dandruffy, and the hair dank and lifeless. To this picture various infective complications may be added. The mucous membranes participate in the disorder; the lips and tongue are often a bright red, the papillæ of the latter being prominent and the former covered with a yellowish superficial crust. Gingivitis and dental caries are almost the rule, but true pyorrhœa is not common. Chronic naso-pharyngeal catarrh is almost invariable, and often associated with the adenoid facies. Every variety of digestive disorder may be found. Fermentative flatulence is one of the commonest. The urine acidity is high. Dr. Barber holds that the essential ætiological factor in producing this state is an alteration in the secretion and composition of the cutaneous fat, which comes to favour the parasitic growth of skin saprophytes. Probably a similar change takes place in the mucous membranes. The disorder is obviously due to some error in the correlation between diet and the expenditure of physical energy. While all of us may be potential seborrhœics, it is possible to escape our fate by the judicious adjustment of diet and exercise

[3] THE LANCET, Feb. 9th, 1929, p. 295.

The normal sebaceous secretion can be altered by the excessive intake of fat or by the ingestion of special forms of fat; excess of carbohydrate and alcohol are known to promote seborrhœa. While admitting adjuvant factors like heredity, age, sexual evolution, and intestinal toxæmia, Dr. Barber maintains that the error of metabolism expressed in the seborrhœic state is to be countered by vigorous out-of-door life with light clothing in a bracing sunny climate.

THE CAUSE OF AURICULAR FIBRILLATION

TWENTY years ago Lewis put the finishing touches to Mackenzie's most important work by proving that "delirium cordis" in the human subject is nothing more nor less than the familiar auricular fibrillation observed in animal experiments. Delirium cordis had long been known to clinicians as a characteristic feature of the later stages of rheumatic heart disease; but, before the investigations of Mackenzie it was generally believed that this peculiar irregularity of the pulse was a result of heart failure. We now know that it is the other way about. It is not the heart failure which leads to fibrillation, but the development of fibrillation which is often the determining factor in precipitating the onset of heart failure. We may now go a step farther and inquire: What is the cause of fibrillation? The answer to that question is considered in a paper by Dr. John Cowan in the current number of the *Quarterly Journal of Medicine*. Cowan points out that there are two types of fibrillation — namely, established and paroxysmal. The former is often associated with definite structural changes in the auricular wall, the result either of an old rheumatic infection or of a degenerative fibrosis. In some cases, however, the auricles are found at autopsy to be devoid of any macroscopic or microscopic evidence of disease. Sometimes, as for example in exophthalmic goitre, the disorder is clearly attributable to a definite toxæmia, and normal rhythm may return when the source of that toxæmia is removed; but at other times one may seek in vain for an adequate exciting cause. This is often true in the paroxysmal type of fibrillation. Between attacks there may be absolutely no evidence of any cardiac defect, the patient appearing to be a perfectly healthy man. As Cowan points out, these paroxysms of fibrillation are frequently associated with flatulence and other digestive disturbances. This he regards as evidence of intoxication from the gastro-intestinal tract; but may there not possibly be an alternative explanation, a reflex disturbance produced through the vegetative nervous system? The innervation of the heart is so closely related to that of the abdominal viscera that it is not difficult to imagine that a disturbance in one part of the vagal field may excite reflexly disorders in more distant organs. It seems probable that many hearts are on the verge of fibrillation, for patients often attribute the onset of their palpitation or distress to some unusual physical effort. Cowan instances spring-cleaning as the provoking cause in one of his patients, and oddly enough it was the wife and not the husband who suffered.

BORIC ACID AS A NATURAL CONSTITUENT OF FOODS.

J. A. Voelcker has shown that boric acid is a necessary ingredient of soils for the growth of many agricultural crops, and E. S. Johnston has come to the conclusion, based on experiments on tomato and potato plants, that boron should be added to the list of elements necessary for plant growth. Boric acid may therefore be expected as a constituent of vegetable food products, and the public analyst and physician alike will want to know to what extent it is naturally present. Two pieces of work reported in the January issue of the *Analyst* are therefore of considerable interest. Mr. A. Scott Dodd, continuing earlier work on the occurrence of boron compounds in cacao products, has examined other fruits and vegetable products. Having regard to the requirements of the Public Health (Preservatives) Regulations, 1925, he has tested certain vegetable products which enter into the composition of cakes, buns, mincemeat, wines, jams, and sauces. He found in currants, raisins, muscatels, and sultanas, both from Empire sources and from Europe and California, an amount of boric acid varying from 0·010 to 0·022 per cent. on the fruit as received, whilst the dry matter contained rather more. In such dried fruits as apricots, dates, cherries, figs, peaches, prunes, pears, and apple-rings, the amounts varied from 0·003 to 0·025 per cent., of the same order as the dried grapes already mentioned. It is worthy of note that the amounts seem to be specific to the species examined. For example, Australian apricots contained 0·022 and Californian 0·023 per cent.; Australian and Californian peaches contained, respectively, 0·025 and 0·022 per cent.; whilst two samples of French and one of Californian prunes all contained 0·003 per cent. Black and red currants, cherries, gooseberries, cranberries, and tomatoes in the fresh condition contained from 0·003 to 0·006 per cent., varying from 0·03 in the dry matter of black currants to 0·109 in that of tomatoes. The large quantity found in the dry matter of tomatoes is interesting in view of Johnston's work on these fruits, but it does not amount to much on the fresh fruit. Minute amounts of boric acid have been found by A. Hebebrand in the juice of oranges and lemons, whilst the Government chemist found mere traces in the edible portions of the fruit. J. T. Dunn and H. C. L. Bloxham found in the peel of oranges from California, the West Indies, and South Africa, from 0·005 to 0·033 per cent of boric acid, and from 0·002 to 0·008 in the pulp. Wines have been found to contain less than 0·01 per cent. It does not appear that any food product in a state adapted for consumption would be at all likely to contain an amount of boric acid approaching what would be added in order to act as a preservative. An analyst would be ill-advised in reporting as added amounts of boric acid less than 1 grain per lb. (0·014 per cent.).

RECENT WORK ON LEPROSY.

ALTHOUGH there can be little doubt that leprosy is infectious, not much is accurately known about the way in which it is transferred or how the organisms enter the body. In a recent paper [1] E. B. Vedder points out that whilst the disease is often familial, close contact does not necessarily favour its spread. Married couples, one of whom is leprous, have lived in intimate relationship as long as ten years without the infection being conveyed and, under experimental conditions, it has been by no means easy to transmit leprosy from one person to another. Thus, between 1844 and 1858, Danielssen repeatedly inoculated himself and other volunteers, numbering 20 in all, with material obtained from leprous nodules and did not get a single positive result. The question of age-susceptibility, which is referred to by an American correspondent on p. 412 of our present issue, is not yet fully understood, but in the Philippines it has been calculated that close and intimate association with a leper for at least two years is required for the transmission of leprosy even to children. The occasional incidence of the disease amongst Europeans who appear to have had no contact, however casual, with lepers, has with other considerations suggested the possibility of transmission by insects, and Vedder records that a study of its epidemiology in the Philippines has been undertaken in the hope that further light might be shed upon the problem. The resultant figures seem, however, to show that some local condition other than contiguity or density of population is the most important factor influencing the spread of leprosy. Under experimental conditions a number of mosquitoes (*Aëdes ægypti*), which

[1] Philippine Jour. of Sci., 1928, xxxvii., 215.

had fed on lepra-infected skin were examined, and undoubted lepra bacilli were found in 41 per cent. of them. They were recognised as lepra bacilli, not only because they were acid-fast, but because of their characteristic grouping. Courageous transmission experiments were made upon three volunteers secured from Bilibid Prison. All were young men in perfect health. The first was inoculated intradermally on March 29th, 1927, with material from a leper tubercle, but up to June, 1928, none of the signs characteristic of leprosy had developed. The remaining two were subjected to the bites of large numbers of *A. ægypti* with ingested lepra bacilli, but up to the time of writing these victims also had remained free of leprosy.

In connexion with the treatment of leprosy it may be noted that Olpp [2] of Tübingen, has been trying the effects of giving potassium iodide by the intravenous route, and states that the clinical improvement in six weeks was equal to what might be expected after a year's treatment with the chaulmoogra derivatives. Several reactions in the leprous lesions were encountered and can be classified, he says, under four headings—local reaction in already existent lesions; bacillæmia; the appearance of fresh minute leprous lesions in the skin; and a rise of body temperature in proportion to the nature of the lesions. In nodular leprosy, or in leprous involvement of the skin, the initial dose of potassium iodide is 0·06 g., but this dose is daily increased by 0·06 g. till such a time as a reaction sets in. In nerve leprosy, or the anæsthesic forms, the initial dose is 0·3 g., increasing by the same amount daily up to 1·8 g., or until a reaction sets in. During treatment the body temperature should be taken at least four times daily. The increased sedimentation-rate of the red blood corpuscles and the appearance of a definite leucocytosis are both indications of the favourable reaction of potassium iodide. Undoubtedly the potassium iodide method introduced by Muir has already achieved remarkable success, and its ultimate consequences cannot as yet be accurately foreseen.

NEUROLOGICAL PROBLEMS CONNECTED WITH LABOUR.

THREE papers bearing on the immediate and remote effects of intracranial birth injury, written from somewhat different standpoints, may be found in the *Journal of the American Medical Association* for Jan. 12th. Prof. H. Ehrenfest attempts to answer the question "Can intracranial birth injuries be avoided?" He considers that some degree of trauma to the nervous system, probably in the form of contusion of the brain, is so common as to be properly regarded as physiological, and that minimal lesions of this kind are unlikely to produce lasting effects. The liability of the human infant to this form of trauma is attributable to the presence of fontanelles and sutures; in control experiments on new-born mammals with thick skull bones and no fontanelles they were never observed. The truly pathological lesions of the brain (gross hæmorrhage) are caused in two principal ways: (1) distortion or compression of venous sinuses, and abnormal stresses exerted on the dural septa; and (2) the "suction effect" described by P. Schwartz—i.e., the difference between the intra-uterine pressure after rupture of the membranes and the atmospheric pressure to which the presenting part is subjected after dilatation of the os. Trauma of the first type is undoubtedly possible when pressure of any kind is applied with undue rapidity. Prof. Ehrenfest recommends as a prophylactic measure "absolute non-intervention during labour that is progressing normally, excepting in this respect an episiotomy and truly perineal forceps applied to a maximally compressed head." He considers that by this policy the "physiological" trauma may be reduced to its possible minimum; he also suggests that harm may be avoided if every infant which shows signs of asphyxia is regarded as probably suffering from intracranial trauma, and is not subjected to any vigorous measures of resuscitation.

Dr. Bronson Crothers discussed the mechanism of labour from the point of view of the neurologist. He reminds the reader that the hemispheres have little or no function in the new-born, and that the viability of the infant depends on the integrity of the tissue lying between the tentorium and the upper part of the cord. This area is protected from direct injury by the relatively rigid base of the skull and the muscles of the neck; it is also guarded by the tentorium from pressure transmitted from above. The supratentorial portion of the brain, however, is protected by far less rigid bony walls and is subjected to the alterations of form and pressure occasioned by moulding. Considerable distortion of this area may occur without producing effects which are immediately dangerous to life. On the other hand, should any sudden increase of stress cause a rupture of the tentorium an injury will result which is usually fatal, either from hæmorrhage or from the pressure exerted upon the bulbar centres. Dr. Crothers is in agreement with Prof. Ehrenfest that forceful measures of interference are likely to increase the dangers of fatal cerebral hæmorrhage. But he speaks also of the other side of the question, which does seem to present something of a dilemma; for undue delay in delivery also has its dangers in that it favours the occurrence of the "suction-bleeding" already referred to, the effects of which are less evident to the obstetrician but are afterwards of concern to the neurologist. Dr. Crothers further draws attention to the dangers of traction on the breech, and to the lesions of the cord which this unphysiological procedure may produce.

Dr. P. L. Schoeder has investigated the possible relation between birth injury and "behaviour difficulties" in childhood. He gives details of two groups of children, one showing evidence of infantile cerebral palsy, and one in which a history of cerebral birth injury was obtained. The traits included under "behaviour difficulties" are so varied and so numerous that his cases are not always clearly distinguished from the normal. A good deal of retardation was found in both groups, and Schoeder attributes their behaviour difficulties to a large extent to this factor, the difference in behaviour between the groups being accounted for by "orthopædic handicap." He infers, on evidence which seems by no means conclusive, that "distractability and hyperactivity" should be added to the classification of the results of birth trauma. Before subscribing to this opinion we should wish to investigate and compare the incidence of these extremely common characteristics of childhood in children who do not show a history of cerebral trauma.

[2] Münch. med. Woch., Jan. 4th, 1929, p. 13.

PROF. JEAN SICARD.

Jean Sicard, whose sudden death occurred at his home in Paris a few days ago, has been called by Prof. Dumas the "Healer of Pain." His title to this description depends on his researches into the mechanism of pain at a period when little distinction was made between various forms of pain, and treatment was correspondingly empirical. To neuralgism he gave a sympathetic origin, and secondary neuralgias he traced to their respective sources, trying to evolve a rational and differential system of ætiological treatment. Sympathetic neuralgism he treated with heat and X rays, secondary neuralgias by operative or other means, and "douleurs essentielles" by local means—destruction of sensory nerves, and so forth. From 1899 onwards he devoted much of his time and energies to investigation into the properties of the cerebro-spinal fluid, correlating them with various morbid conditions of the central nervous system. But the sphere in which he was most widely known, and the pioneer work with which his name will always be most intimately associated, concerns his diagnostic

injections of lipiodol. His investigations in this field began with the observation that skiagrams of different parts of the body into which this substance had been injected showed it to be impermeable to X rays. He exploited his observation as a means of demonstrating lesions in almost every part of the body, but it was the nervous system in particular that he illuminated by this device, demonstrating the exact position of lesions which had given rise to signs of compression. While making injections of luargol, he noticed that it clotted blood in the veins, and from this isolated observation he was led to devising treatment of varicose veins by means of intravenous injections of various drugs, first luargol, later sodium carbonate, and finally sodium salicylate, the employment of which in the injection treatment of varicose veins is still advocated by many. These examples of Sicard's work should suffice to show what manner of intellect he possessed. Apparently small things which the crowd overlooks were not only carefully noted, but were also applied to the solution of difficult problems, being made the starting-point of new ventures and discoveries. He would pick up an old key in the gutter, polish it, and then pop it into the keyhole of the nearest locked door, thinking it might peradventure open it. And when it happened to do so, and he found great store of treasure therein, he was quick to put it in order, to tidy and classify it, and then to give it to all the world with open hands. It is a pity that the taste for picking up keys in the gutter is only congenital and not to be acquired by laboured conscientiousness.

MEDICAL EDUCATION IN THE SOVIET UNION.

WITH all its reputed disadvantages, Soviet government seems to have brought about great development of the study of medicine in Russia. According to a recent article by Dr. Nikolai Messis,[1] medical study before the Revolution was handicapped by many political restrictions. There were only eight Government schools, which excluded women and restricted Jews to a quota of 3 per cent.; seven private institutions were in existence. As soon as the Czarist Government was overthrown, the State schools were overwhelmed with applicants, and by 1924 the number of students reached 47,000 and the number of schools had been increased to 30. The supply of qualified men and women soon exceeded the demand, which is for not quite 25,000, and the Government have restricted the number of new entries by imposing certain conditions of selection. Applicants from the working classes are given preference, and bursaries have been founded to assist them; the number of these in 1924 was 8671 in Russia alone, not counting the other autonomous Soviet States. Other bursaries are maintained by the various industrial organisations for their own members. The schools are administered by faculties elected by the staff and the students, which latter are represented upon the governing body and the subcommittees which have charge of the various departments and provide a certain number of the members of the executive committee—half the number representing the teaching staff. The executive committee also contains representatives of the Government and the trade-unions, and the medical committee representatives of the unions of the medical personnel. The schools as a whole come under the Peoples' Commissary for Education, who is assisted by a scientific committee. The course, fixed in 1924, lasts five years and aims at restricting the preparatory studies in anatomy and physiology as much as possible. They are to be completed in two years, and the remaining three are devoted to medicine proper; the syllabus lays great stress on the necessity for introducing the student at once to the practical work of the laboratory and clinic. There are two post-graduate schools, one at Leningrad and the other at Kasan, on the Volga, while post-graduate and specialist courses are provided at many other clinics. In the year 1926–27 these attracted no less than 2716 doctors. The courses include a study of the work of the special clinics for tuberculosis, venereal disease, maternal and child welfare, orthopædics, and physically and mentally defective children—institutions which have multiplied with great rapidity under the Soviet.

SPURIOUS PRECISION.

THOSE with any critical knowledge of chemistry must be filled with amazement at the varied ways of stating the results of mineral-water analyses and the precision which is sometimes claimed. It is, for example, startling to see that the water from a "source thermale" in Luxembourg contains in 1 kg. 15·433434 g. of solids, of which 9·4148 g. is sodium chloride, and 0·45487 g. is hydrocarbonate of magnesium; more especially when one reflects that Stas, at the not far-distant University of Louvain, did not achieve such accuracy in his classical determination of atomic weights. At its last meeting, the International Society of Medical Hydrology adopted certain resolutions[1] which should clear up some of these points. Among other things, it is recommended: that the analysis of a water shall always be expressed in terms of ions, whether its interpretation in other terms is given or not; that the quantities of ions, also "salines" when given, shall be given to one decimal place only, or when the quantity is less than ten, to two significant figures; and that the analysis shall be in terms of parts per million, either as mg. per litre or mg. per kg. It is hoped that international standard measurements may be used in the publications of spas and in national handbooks, and in this and other ways the recommendations should simplify the task of the physician who has to compare different waters. It is by no means easy to convert grains per pint into parts per 100,000 or cubic inches of gas per gallon into millilitres per litre.

A MEDICAL COUNCIL FOR INDIA.

IT has long been apparent that the provincial medical councils, useful as they have proved in many respects, have not been capable of dealing satisfactorily with some questions affecting India as a whole, and the renewal of proposals to establish a council for the whole of India, which have twice been put forward during the last eight years, comes as no surprise. The text of the Bill to effect this object which is at present under consideration is in some respects still being treated as confidential, but the general tenour of the proposals is known, and they are discussed in the January number of the *Indian Medical Gazette*. The functions of the provincial medical councils are the maintenance of medical registers, with corresponding disciplinary powers, and authority to require particulars of the examinations of institutions included in their schedules, and to depute visiting members to be present at such examinations. These functions have, no doubt, been satisfactorily fulfilled, on the whole, but the time has now come when a central body for India is urgently needed, in order to obtain uniformity in the educational standards of the various provinces, and also to negotiate with British, colonial, and foreign licensing bodies, or other authorities, concerning proposals for reciprocity and other matters. For some time past, as is generally known, difficulties have arisen periodically with regard to the recognition of certain Indian medical degrees, and it is an open secret that representations from the British General Medical Council with regard to the desirability of instituting some more centrally responsible authority than at present exists have been instrumental in bringing up the subject again with increased urgency. Its consideration was at first complicated by the fact that there is not only the graduate class to be considered—the class, that is, which is generally eligible

[1] Archives of Medical Hydrology, January, 1929, p. 153.

for registration in Britain—but also the non-graduate or licentiate class, which is not educated on the same lines, and cannot aspire to such recognition. The present governmental proposals evade this difficulty by dropping the licentiates and confining themselves to the graduates. No doubt this is convenient, and it may be necessary for the time, in order to avoid delay, but it is to be hoped that the licentiates also may eventually be brought into the orbit of the central council. It is, in fact, the licentiate class which is most in need of regularisation. The diplomas of the various provinces vary to a much greater extent than the degrees, and one of the most useful functions of an all-India council would be to correct these discrepancies. If the present proposals are approved, the powers of the provincial councils with regard to the graduate class will pass to the central body, leaving the provincial councils to deal with the licentiates alone. The *Gazette* suggests, however, that as regards disciplinary work it would seem more convenient that for graduates as well as licentiates, action should first be taken by the provincial councils, appeals being allowed to the central council if desired. The difficulty of hearing disciplinary cases from the whole of India in one central locality would certainly be great, and this suggestion is worthy of note.

Subject to any modifications which are found necessary, we may agree with our contemporary that there can hardly be any reasonable grounds on which objection can be taken to the objects of the Bill, and that the establishment of a central medical council for the whole of India would not only mark a great advance in the organisation of medical education, but would place the Indian Empire in a much better position to negotiate with the outside world on questions such as the mutual recognition of qualifications and other matters of medical policy.

THE VARICOSE ULCER.

FROM all sides observers are sending in accounts of their experiences with the injection treatment in the obliteration of varicose veins. This treatment is so simple, so effective, that it has ousted almost completely the treatment by operation. It is not applicable to every case, and it is open to argument that where Trendelenburg's sign is positive it may be well to tie the internal saphenous vein besides injecting it lower down. But, on the whole, it can be said that the injection methods now generally adopted are suitable for routine use. The risk is less than operation and the results are better. When the veins have been obliterated there remain the varicose ulcers to consider in many cases. In a recent Hunterian lecture at the Royal College of Surgeons of England, Mr. R. T. Payne recorded his observations on the healing of these ulcers after injection treatment. Among patients at St. Bartholomew's Hospital he obtained striking success; when thrombosis was achieved, 87 per cent. of the ulcers healed so as to allow the patients to carry on their usual occupations. In the other 13 per cent. there was very great improvement. How rapidly healing will be brought about seems to depend more than anything else on the depth to which the ulcer has penetrated, and particularly on the participation of the underlying bone in the inflammatory process. Mr. Payne finds that a prognosis can be based upon skiagraphic findings; the greater the changes in the underlying bone the greater the difficulty in bringing about a cure. In the patients who were cured no particular local treatment was given beyond washing the surface with boiled water, applying a calamine lotion, and cleaning up the ulcer with ether at the weekly visit to hospital. These results clearly indicate that the paramount factor in the persistence of varicose ulcers is interference with venous drainage. There are more ways than one of influencing the circulation of the lower limb and bringing about a cure; the method of Prof. R. Leriche is to tie the internal saphenous vein, sever the sympathetic sheath of the femoral artery, and excise the base of the ulcer. After an interval skin is grafted on the base of the ulcer. The sympathectomy not only improves nutrition of the part but leads to a sterilisation of the surface of the ulcer. By this means he has caused ulcers to heal which have lasted for very many years. It seems that we now have methods of curing these very intractable affections, the first choice being a trial of injection. Should this fail resort might be had to Leriche's method, which requires a period of hospitalisation.

PAUL UNNA.

WITH the death of Unna, in his seventy-ninth year, there passes the last of a long series of German and Austrian dermatologists that began with Hebra and Kaposi, and produced such geniuses as Neisser. He had lived so long that his name had become a tradition—a tradition which will last as long in dermatology as the name of Richard Wagner in music. Between these two men there are other resemblances which render a comparison interesting. Both were highly original, and followed no paths but of their own making. Their work and opinions were unconventional, and both were thus in conflict with the spirit of their times. In each case the result was a certain professional isolation, or at least the none too popular foundation of a cult—the one at Bayreuth and the other at Hamburg, where it was not until 1919, when he was 69, that Unna was granted for the first time the title of full university professor. Judged by the standard and importance of his contributions to dermatology, the honour must have been long overdue, and there can be no doubt that he was a great teacher and efficient therapeutist, for students and patients flocked to his private clinic from all parts of the world. The founder and for many years the most regular and important contributor to the now flourishing *Dermatologische Wochenschrift*, there was no branch of dermatology outside his knowledge or the diligence of his microscope and pen. Three great works punctuated an even flow of minor contributions—namely, Contributions to the Histology and Development of the Human Skin and its Appendages [1] (1876); the Histopathology of the Skin (1894); and the Histo-chemistry (Histochemie) of the Skin (1927). He published a book on cutaneous therapy, and in coöperation with the well-known firm of Beiersdorf, invented a new technique for the treatment of localised dermatoses and tumours by incorporating therapeutic ingredients in standardised proportions in adhesive plasters and plaster-mulls. The closing years of his life were unattended by the usual clouding of mental and bodily vigour, and during these years he received the recognition of his fellow countrymen. To hear him respond to the toast of "the Father of Dermatology" at the Dermatological Congress of Bonn in 1927 was to see him honoured as he always deserved, a notable pioneer and leader in an increasingly important branch of the healing art.

DONATIONS AND BEQUESTS.—Mrs. Margaretta Hill, Bexhill-on-Sea, left bequests including £1000 towards the fund for building and endowing a hospital at Bexhill, £150 each to Queen Mary's Hospital for the East End, Stratford, and the Woodford Jubilee Hospital, and £100 to the South London Institution for the Blind.—Mr. Joseph Pugsley, of Edney's Mount, Staplehill, Bristol, left £1000 each to the Bristol Infirmary and the Bristol General Hospital, and £300 each to Bristol Royal Hospital for Sick Children, Muller's Orphanage, Ashley Down, and Bristol Eye Hospital.—Mr. Charles Montague Fox, of Brentford, left a sum sufficient to endow a bed in St. Mary's Hospital, Paddington.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

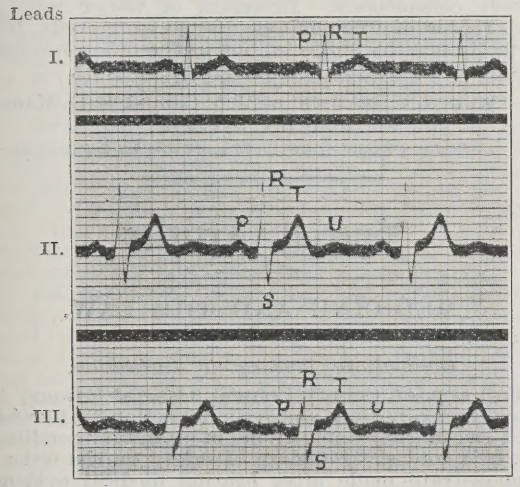
XXIII.—THE ELECTROCARDIOGRAM.

PART I.*—NORMAL RECORDS.

The Value of Electrocardiography.

THE busy practitioner who has little time for specialised reading is often at a loss to know what kind of phenomena the electrocardiograph records, and when it is likely to furnish information helpful to him in his practice. His difficulty may lie in understanding the physical principles on which the method is based. Whereas a tracing of the arterial or venous pulse is merely a graphic representation of something he can feel or see, the electrical phenomena accompanying the heart beat are less familiar to him, for they cannot be appreciated by the unaided senses.

FIG. 1.



Record showing normal differences in the three leads. (3 m.v. = 2 cm.)
Electrocardiograms are generally calibrated so that an electromotive force (E.M.F.) of 3 millivolts gives a deflexion of 3 cm. when the camera is placed at a distance of 1 metre from the galvanometer. The author prefers to take them with the camera nearer to the galvanometer, so that 3 m.v. gives a deflexion of only 2 cm. with the string at the same sensitivity. This makes it possible to get a larger number of cycles on a single plate and at the same time to preserve the normal relative proportions of the curve. Provided the calibration is stated, its actual value is immaterial.
The horizontal lines are 1 mm. apart.
The vertical time lines in the plate are separated by intervals of 0·2 and 0·04 sec. respectively.

Even the general physician is not always clear about the scope and limitations of the subject. Impressed by the fact that in its early days clinical electrocardiography was of value in distinguishing the different types of irregular heart action, and knowing that these can now generally be recognised without its aid, he is apt to think that the method has outlived its usefulness. He does not realise that, when he first began to use the electrocardiogram to detect auricular fibrillation, those who were making a special study of the subject had already passed on. Having charted and signposted the arrhythmias, they were then exploring new ground. They were investigating disorders of the cardiac function in which the regular rhythm of the heart was undisturbed. They were becoming acquainted with the modifications in the electrocardiogram produced by degenerative processes in the walls of the ventricles, by coronary thrombosis, and by the action of digitalis and other drugs. Even now there are many abnormalities of the electrocardiogram the significance of which is still obscure, and there is reason to hope that some of these may prove to be the clues to clinical problems yet unsolved.

FIG. 2.

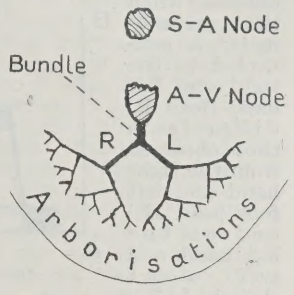


Diagram of nodes and bundle. R and L = right and left branches of bundle.

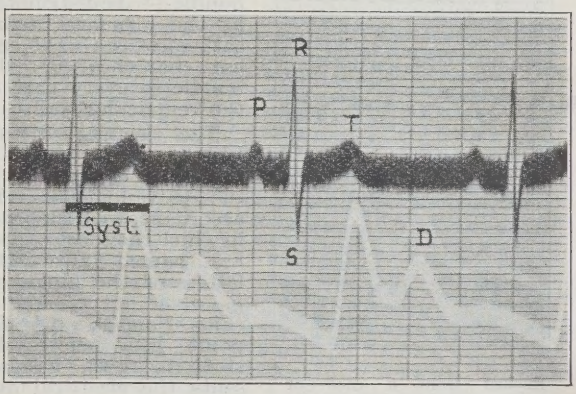
In the preface to the fourth edition of his "Clinical Electrocardiography" published only a few months ago, Sir Thomas Lewis says: "Cases of structural heart disease are few in which an electrical examination is superfluous, and in not an inconsiderable percentage of cases the records modify, more or less profoundly, our conceptions of the malady that we treat." The value of the method as an aid to diagnosis requires no further emphasis; but there is another aspect of the subject which is perhaps less obvious. The careful physician never fails to profit by the opportunity of verifying his clinical findings at autopsy; for he realises how much he has to learn from his mistakes. Fortunately for the patient, recovery frequently robs him of this check. Not so with the pathology of the living heart; for when the electrocardiograph is available it can often supply the information we require. By enabling us to detect errors in clinical diagnosis which otherwise would pass unnoticed, it sharpens the faculty of observation, and at the same time serves to remind us of our limitations.

In many derangements of the cardiac mechanism electrocardiography enables us to see clearly what is happening and to follow step by step the development of a disturbance of function, where, without its aid, the end-results alone would be apparent; it permits us in fact a glimpse behind the veil which cloaks the fundamental processes of disease. Thus, in the interests of the patient, additional facts concerning his particular case may be brought to light, while the physician has a ready means of checking and supplementing his clinical observations. Like the quality of mercy the electrocardiogram "is twice blest; it blesseth him that gives and him that takes."

FIG. 3.



Synchronous electrocardiogram and radial sphygmogram to illustrate time relations of ventricular systole (syst.). (3 m.v. = 3 cm.). D = Dicrotic wave.

The Normal Record.

By placing on the surface of the exposed heart a pair of electrodes, connected to a rapidly moving galvanometer, sudden changes of electrical potential

* Part II., Abnormal Records, will appear next week.

accompanying each heart-beat can be demonstrated. For clinical purposes it is obviously impracticable to place electrodes directly in contact with the patient's heart; but since the currents produced within the heart spread to all parts of the body, their presence can be made manifest by connecting the galvanometer leads to the hand and foot. The curves (Fig. 1) obtained when the galvanometer is connected to the right and left hand (lead I.) differ from those obtained from the right hand and left foot (lead II.) or from the left hand and left foot (lead III.). This is due to the fact that the electrodes in these three leads are disposed in different planes; hence one lead is more favourably situated to record one phase and another another phase of the electrical disturbance. For this reason it is always desirable to study the electrocardiogram in more than one lead, remembering that lead III. exhibits the greatest variation in normal subjects.

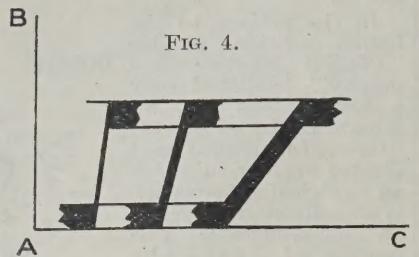


FIG. 4.

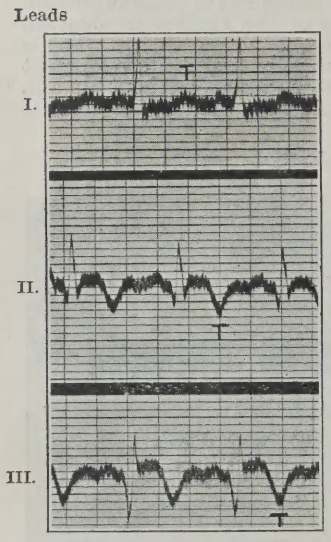
A–B, differences of electrical potential; A–C, time.

The electrical disturbance associated with cardiac contraction first makes its appearance in a localised collection of specialised tissue in the wall of the right auricle, known as the sino-auricular node (Fig. 2). Thence it spreads, like a ripple on a still sheet of water, over the musculature of the auricles, and eventually reaches a second collection of specialised tissue known as the auriculo-ventricular node. Leaving the A-V node the excitation wave enters a special conducting strand—the auriculo-ventricular bundle—to be distributed by the ultimate ramifications of the right and left branches of the bundle to every part of the ventricular wall.

FIG. 5.



Record from a case of coronary thrombosis, showing large inverted T in leads II. and III. (3 m.v. = 2 cm.).
The very rapid small oscillations, which are especially pronounced in lead I., are due to tremor of the somatic muscles.

The electrical disturbance gives rise to a series of deflexions in the galvanometer. In accordance with the order in which they occur, these are named after the letters of the alphabet. P, Q, R, S, T, and U (Figs. 1 and 3. Q is the point just before the steep rise to R). P represents the electrical disturbance associated with auricular systole, Q, R, and S the rapid changes of potential as the excitation wave spreads quickly through the A-V bundle and its branches, and T the more gradual subsidence of the state of excitation in the ventricle. U is an inconstant feature the significance of which has not yet been determined. Normally throughout the interval between S and T the galvanometer remains at rest in the zero position, since the whole mass of the ventricular muscle is in a state of excitation, and its different parts are all at the same electrical potential.

The varying thickness of the lines in different parts of the record sometimes puzzles those who are unfamiliar with graphic records. The explanation is very simple. The ordinates (A–B, Fig. 4) represent differences of electrical potential, whilst the abscissæ (A–C) represent time. The greater the vertical displacement in a given horizontal distance, the thinner the line.

The electrocardiogram is more personal than most graphic records. In the same individual, in health, its features remain remarkably constant; whereas it is rare to find two records from different subjects which are exactly alike. There are, however, certain points of similarity which enable us to differentiate the normal from the pathological, and in reading an electrocardiogram the principal features which demand attention are the direction, amplitude, duration, and time relations of the different deflexions.

In normal records the amplitude of the R wave appears to be related to the condition of the ventricular muscle. It tends to increase during convalescence from an acute illness and to diminish after a prolonged and severe physical effort. R waves of very large amplitude are frequently found in records from excitable overacting hearts, as in the case of patients suffering from exophthalmic goitre. Similarly in electrocardiograms from normal people the T wave is always conspicuous. Inversion of the T wave in lead III. is of frequent occurrence in records from perfectly healthy subjects, but in the other two leads it is generally regarded as abnormal (Fig. 5).

CRIGHTON BRAMWELL, M.A. Camb., M.D. Manch., M.R.C.P. Lond.,
Assistant Physician to the Manchester Royal Infirmary.

Special Articles.

MEDICINE AND THE LAW.

Compulsory Removal to Institution.

THE London County Council (General Powers) Act of last year contained a provision (Section 28) by which aged and infirm persons living in insanitary conditions can be removed to a place of safety on the order of a magistrate made after hearing medical evidence. What is stated to be the first order made under this power in London was made last week in the case of a woman of 77, an old-age pensioner, whose condition of living, surroundings, and need of skilled care and nursing were described in evidence by Dr. F. L. Keith, the medical officer, on an application on behalf of the Bethnal Green Borough Council. The new statutory power is a development of the power to compel removal to hospital of persons suffering from grave infectious disorder; similar clauses are to be found in the Sheffield Act of last year (Section 160), the Rotherham Act of last year (Section 101), and the Leeds Act of 1927 (Section 95). The general procedure has affinities with the machinery for certification and detention order under the Lunacy Act. Presumably no aged and infirm persons will bring actions for damages against a medical practitioner for alleged negligence in certifying them to need skilled care and nursing, and to require removal to an institution. As in the case of the Lunacy Act procedure it is the magistrate's order, and not the medical witness's evidence, which deprives the patient of liberty.

Imprisonment for Bogus Doctor.

Though causing a certain inconvenience to registered practitioners, the Dangerous Drugs Acts are proving a positive check to the unregistered. A man who admitted to the police that he possessed no degrees under the General Medical Council, and who pleaded guilty at Wallasey last week to charges of obtaining money by false pretences, was able to pose as a doctor and to prescribe drugs for patients with impunity until he included elixir heroin in his range

of drugs. The chemist informed him that it was a dangerous drug and that a prescription must be given for it, together with information of the name of the patient. The accused, who had been in the habit of marking prescriptions "W. H. Rankin, M.D.," wrote a name on a slip of paper and spelt the word heroin wrongly. This aroused suspicions, the police were communicated with, and they found the pretended doctor attending a patient at New Brighton. He was sentenced at Wallasey to 12 months' imprisonment with hard labour. It was stated that he was known by nearly all the police throughout the country. Here, therefore, the Dangerous Drugs Acts are the public's only safeguard.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Locum Tenent's Fees in the Dispensary Medical Service.

THERE has long been discontent in the Irish dispensary medical service over the rate of payment offered by boards of health to temporary medical officers. A locum tenens was engaged in a hurry, and unless he had an agreement with the board of health as to the amount of his fees he was likely to find himself put off with any sum the board thought fit to offer. It is, therefore, with some relief that medical men who are in the habit of performing temporary duty in the medical service have learned of the order recently issued by the Department of Local Government and Public Health to the Westmeath County Board of Health. Some time ago, in face of a demand from the medical profession of the county for remuneration at the rate of six guineas a week, the board passed a resolution that the rate should be four guineas. The department has directed that certain medical practitioners to whom fees were owing should be paid at the rate of five guineas a week, and that in future at least five guineas is to be paid for temporary duty in any full-sized dispensary district. The Minister added that he would not concur in any lower rate of payment. That the department does not intend to establish the rate of five guineas as a fixed standard is shown by the use of the words "at least," and by its direction to the Wexford Board of Health recently to pay at the rate of six guineas, that being the accepted scale in that county.

Resignation of Colonel Higgins.

It was announced last week that Colonel Thomas Higgins, who has been head of the medical service of the Irish Free State Army since 1923, has resigned his post. Colonel Higgins accepted command of the medical service shortly after the civil war ceased in Ireland, and on him fell the responsibility of organising the service on a peace basis. He tackled the various problems that arose with much ability, and his resignation is a distinct loss. It is announced that he has been selected as the Government Party candidate for the by-election for the Dáil which is shortly to take place in North Dublin. Colonel Higgins is a brother of the late Mr. Kevin O'Higgins. Before joining the Irish Free State Army Medical Service he had experience as a dispensary medical officer in the Midlands of Ireland, and as an officer in the Royal Army Medical Corps.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Change in the Character of Syphilis.

AT the recent meeting of the Interhospital Association Prof. Arthur Sarbó stated that syphilis is treated at present much more effectively than in former times; this is proved by the fact that reinfection is much more frequent. It is accepted that inadequate salvarsan treatment stimulates the spirochætes; this explains a recent observation that the incubation period of general paralysis has become much shorter. Owing to unsatisfactory treatment many neuroplegic cases used to occur. This circumstance induced Prof. Finger, the renowned venerologist of the Vienna University, to attempt to bring salvarsan treatment into disrepute. The character of syphilis has also changed in tropical regions since civilisation has reached them; the best proof of this is the relative scarcity of skin and bone lues. Under the influence of treatment it is probable that the life-history of the spirochætes also undergoes a change and that they hide themselves in the adventitia of the blood-vessels, where the soil is most favourable. Thence they may get into the various organs, through the blood, and multiply there, when the resistance of their hosts begins to weaken. In aged persons the incubation stage is shorter than in younger subjects, the reason being their diminished resistance and general debility. That spirochætes produce symptoms in the nervous system sooner than in other organs, Prof. Sarbó holds, is due to the fact that even the smallest lesion in the nervous system is liable to cause manifestations. Moreover, though the liver and kidneys are very sensitive to spirochætes, lesions in these regions are not easy to diagnose, since the healthy portions of these glands can take on the work of the destroyed parts, so that the pathological process is not detected.

Acoustic Apparatus.

Dr. Verzár, a lecturer in the University of Budapest, has recently reviewed the different types of acoustic apparatus and has set out their functions and defects. These devices serve two purposes: (1) to check loss of sound energy, and (2) to increase resonance by the use of (*a*) drums and (*b*) microphones and telephones. The earliest artificial aids to hearing (the ear tubes) were constructed in order to conserve sound. They were flexible, fairly hard tubes, about 2 metres long, with mouthpieces at one end and earpieces at the other. With the aid of this appliance the patient was able to hear the voice of a speaker 2 metres away as if the latter were speaking right into his ear. The appliance does not alter the character of the voice, and is free from adventitious noises. Its disadvantage, apart from its conspicuousness, is that it is suitable only for a dialogue. Much greater is the sphere of usefulness of ear-trumpets provided with resonating drums. Of this type are the constructions made of ebonite, metal, wood, or other materials in the form of pipes or bells, with a hollow mouthpiece leading to a thin tube with an adapter for insertion in the ear; some trumpets are portable in the pocket, being telescopic. The advantage of trumpets is that they can be turned towards the direction of the sound. They receive sound waves coming from a distance of 2–3 metres, and convey these into the ear, amplified 20–30-fold. Moreover, weaker sounds coming from a greater distance also become amplified if the apparatus is tuned to those sounds. The disadvantage of trumpets is that their resonating capacity is not even—certain sounds are made unduly loud at the expense of others, and therefore speech becomes indistinct and colourless. To this defect is added the noise caused by the vibrations peculiar to the particular appliance, which cannot be eliminated, and the conducted noise of the outer world. These circumstances greatly interfere with the serviceableness of this kind of apparatus, which is, moreover, conspicuous, and for this reason alone unpopular. Inconspicuous devices which can be sunk in the hollow behind the ear, or in the external meatus, are for the most part swindles, sold by unscrupulous quacks. As regards the electric appliances, nowadays much advertised, these consist of microphones, dry batteries, and telephones. Owing to the unequal strengthening of the sounds and the long crackling and rattling noises they emit they are no less imperfect than the older forms, their only

advantage being that they are less conspicuous. Dr. Verzár spoke also of artificial ear-drums. Their simplest form is a thin tissue of wadding soaked in paraffin oil. Any doctor, or even the patients themselves, if they have been taught how to do it, can introduce the tissue deeply into the external meatus. Sometimes the effect is surprisingly good, but only in certain cases; these include dry perforation of the ear drum, scarred tympanic membrane, and the presence of a cavity following healing after a radical operation. Unfortunately, these artificial drums may act as foreign bodies and induce inflammation when they have to be removed. They are contra-indicated in all purulent processes, and particularly in cases of cholesteatoma. Whatever service any of these appliances may render, none approaches the method of lip-reading. All patients afflicted with impaired hearing learn this method naturally, and it is taught in all institutions for deaf people.

Jubilee of Prof. Karl Schaffer.

The fortieth anniversary of the scientific activities of Karl Schaffer, professor of neuropathology in the University of Budapest, was celebrated a few days ago. Prof. Lenhossék greeted Prof. Schaffer on behalf of the Hungarian Scientific Academy. He emphasised the prominent talents shown already in his early youth, the first manifestation being his classic work on the horns of Ammon. After 40 years of ceaseless toil Prof. Schaffer shows no sign of exhaustion, and has recently published an excellent treatise on mental diseases and neuropathology, in which he attempts to correlate our present knowledge of neurology, neurohistology, and psychiatry. Prof. Sarbó spoke of the international reputation of Prof. Schaffer and recalled his brilliant lecture on the anatomy of degenerative nerve diseases at the Innsbruck Congress in 1924. Schaffer's pupils have issued a special volume, forming the seventh number of "Hirnpathologische Beiträge," in honour of the occasion. The introductory lines to this work have been contributed by Dr. S. Ramon y Cajal, the well-known Spanish neurologist. On behalf of the professorial board of the Hungarian universities Prof. Preiss paid a tribute to Schaffer's work, recalling their common studies in the pathologico-anatomical institute of Prof. Scheuthauer, of the University of Budapest.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Medical Organisation in the West.

THE States which lie immediately to the east of the Rocky Mountains constitute an enormous geographical area with a small and widely scattered population—just how scattered it is hard for an Englishman to realise until he has driven his car 50 miles or more along a mud or sand road without seeing even a sign of human habitation. In Arizona, where one can see further and see less than anywhere else in this continent, the county medical societies are sometimes limited to three members. To increase the size of the unit by combining counties is impossible; many of them are as far as 150 miles from their nearest neighbour, in one case 200 miles away. Yet among these small societies there are many shining examples of keen intellectual coöperation. Formal papers are rarely presented, but the doctors come together perhaps twice in the month and discuss case-histories that have been previously circulated. In Wyoming there is not one county society that can boast of more than 30 members; yet men will travel 400 and 500 miles to attend a meeting of the State society. A case of malaria diagnosed in one of the Wyoming hospitals recently was enough of a rarity in that region to bring physicians 200 miles to examine the patient and the preparations made from his blood.

Certainly there is no lack of civic consciousness in these great open spaces; witness the progressive programme of the State medical society of Nebraska. They have made themselves responsible for a regular series of lectures on health and medicine in the State normal school. They are also holding exhibits at the annual State Fair which attracts one-third of the whole population of the State. There is a child welfare demonstration, there are illustrated lectures and moving pictures on health subjects, and free medical examinations of the apparently well visitors who ask for them. The people of Nebraska are learning from their doctors the value of practical preventive medicine. One wonders whether the more elaborate medical organisations in the advanced centres of civilisation are achieving more.

Leprosy.

A statistical study of the 34 years' experience of the National Leprosarium at Carville, Louisiana, has produced some interesting results. While the disease sometimes seems almost to have exterminated the families attacked, still, in the majority of cases (64 per cent.), infection has been confined to one member of the family. As a rule, where familial transmission has taken place, the infected individuals have been exposed intimately for a long time. The incubation period also seems to be almost always long; in five cases it was shown fairly conclusively to have been not less than six years. Taking this figure, it is significant to note that the peak of the age-incidence of leprosy occurs at 21 years for males and 19 years for females, since this seems to indicate that puberty is the age of greatest susceptibility to infection. The mortality-rate has gradually decreased in the institution during the 34 years. Less than 20 per cent. of the deaths of the inmates are directly due to leprosy, though more than half of them may be either directly or indirectly ascribed to the disease. The expectation of life is markedly affected when the disease appears in early adult life, but much less affected after middle age. The average age at onset of the disease is just over 30 years. In the seven years since the Federal Government took over the hospital, 28 cases have been paroled as "arrested." Of these only one has relapsed and been readmitted.

Tularæmia.

The importance of tularæmia and its public health interest becomes more apparent from month to month. The incidence of the disease in man has been reported, as stated in a previous letter, from almost all parts of the United States. In a paper read to the last meeting of the American Medical Association, Dr. Francis was able to analyse no less than 679 case reports, including 24 cases that ended in death. While the recognised cases become more numerous, the possible avenues of infection increase at a still greater rate. Not only rabbits but numerous small rodents, game, fowl, and most recently sheep have been found to suffer from the disease. The possibility of human infection is not limited to contact with the bodies of diseased animals. No less than six different insects are listed by the Hygienic Laboratory as vectors of *Bacterium tularense*—two lice, two biting flies, a bug, and a flea. In addition, the common tick of the Rocky Mountain region, *Dermacentor andersoni* Stiles, which carries Rocky Mountain spotted fever, is unquestionably a carrier of tularæmia too. Infection by bites of insects seems to be commoner in the Western States than in the East, probably because the animal reservoir of infection is much greater in the Western States. Dr. Francis, who is recognised as the outstanding authority on tularæmia, recommends that live rabbits shipped from west to east be quarantined for ten days. Rabbits should only be shipped in winter months when *D. andersoni* has left them for its winter quarters in the ground. He suggests that rabbit meat be kept in the refrigerator for 30 days, after which it is believed all *B. tularense* will be killed

The tick is the most important of the vectors. At least 54 cases have been traced with certainty to this agent, and several others with some probability.

Ticks may harbour the infection throughout their lifetime, and pass it on to the next generation in the eggs. Even crushing a tick in the fingers may lead to infection. *D. andersoni* is one of two species that were described until recently under the single name of *D. venustus*. The other species which retains this title is strictly a tick found on sheep in Texas. Specimens of the Rocky Mountain wood tick were forwarded some years ago from Colorado to the British Museum, where they may no doubt now be found. A more extensive knowledge of its geographical distribution in nature seems highly desirable, though in so far as tularæmia is concerned it is probable that any tick which feeds both on man and on the numerous other animals subject to this disease may act as a carrier

Influenza in Alaska.

The influenza epidemic has invaded the isolated hamlets on the coast of Alaska, and the United States coastguard cutter *Unalga* spent the latter half of December in carrying medical aid to the stricken district. At Hoonah they found 74 of the 75 white inhabitants ill with influenza, and of 380 Indians only 30 had escaped. In the next village were 58 invalids without any medical care. Supplies were left at each port of call, until the village of Kate was reached, where the ship anchored and the medical personnel devoted themselves to the care of the inhabitants.

Public Health Services.

INFLUENZA.

APART from London, where the figures given below speak for themselves, the main incidence of the epidemic in this country is still in the north-west, numerous cases being reported from Manchester and Liverpool, as well as other Lancashire towns. Westmorland, Gateshead, Leeds, Bradford, Sheffield, Derby, Kidderminster, Burton-on-Trent, Luton, Dunstable, London, Newport, Cardiff, and Brynmawr are other epidemic centres. The type of disease is stated in general to be mild, but in Leeds and Bradford cases of pneumonia are on the increase. The disease is subsiding in Portsmouth, and the absence of any epidemic is reported from a number of places such as Durham, Boston, Nottingham, Stoke-on-Trent, and Bristol. In the Army the main incidence is in the Eastern, Northern, and Southern Commands; 672 cases were reported for the week ended Feb. 8th, as against 857 in the previous week.

On the Continent of Europe influenza is still increasing, although mild in type, in North-West Germany, Holland, the west of Czecho-Slovakia, and in some parts of Spain, particularly the north-western provinces. Elsewhere it is decreasing.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 9TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 50; scarlet fever, 2276; diphtheria, 1345; enteric fever, 19; pneumonia, 3898 (last week 3511); puerperal fever, 40; puerperal pyrexia, 141; cerebro-spinal fever, 8; acute poliomyelitis, 8; acute polioencephalitis, 4; encephalitis lethargica, 12; dysentery, 15; ophthalmia neonatorum, 103. No case of cholera, plague, or typhus fever was notified during the week.

The largest number of cases of pneumonia was reported from London, 689 (last week 513); Chester, 172 (151); Durham, 133 (149); Essex, 136 (123); Lancaster, 1102 (965); Warwick, 132 (125); Yorks West Riding, 292 (292); from which it will be seen that the incidence has not risen nearly as rapidly as in the previous week, and is already diminishing in some large centres.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Feb. 12th–13th was as follows: Small-pox (38 under treatment, 1 under observation); scarlet fever, 1853; diphtheria, 2043; measles, 56; whooping-cough, 886; puerperal fever, 18 (plus 4 babies); encephalitis lethargica, 79; poliomyelitis, 5; "other diseases," 62. At St. Margaret's Hospital there were 10 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 57 (1) from measles, 19 (4) from scarlet fever, 186 (76) from whooping-cough, 62 (12) from diphtheria, 52 (8) from diarrhœa and enteritis under two years, and 987 (331) from influenza. The figures in parentheses are those for London itself.

The number of deaths from influenza during the previous eight weeks was 61, 69, 83, 99, 122, 179, 321, and 652 respectively. The figures for London during the same period being: 9, 9, 15, 18, 34, 39, 77 and 198, from which it is seen that the rate of rise, being still steep in London, is moderating for the rest of the great towns. In the week under review deaths were attributed to influenza in Manchester, 99; Liverpool, 82; Portsmouth, St. Helens, and Leeds each 25; Salford, 19; West Ham, 16; Wallasey, 15; Southampton, 14; Stockport, 12; Leicester, Birkenhead, and Bolton, 11 each. No other great town had as many as 10. Glasgow reported 62 instead of 236 and 184 in the previous weeks. Belfast 52 in place of 105, and Edinburgh 65 during the same week. The three deaths from enteric fever outside London occurred at Hendon, Southend-on-Sea, and Sheffield. Liverpool reported 12 deaths from measles, St. Helens and Sunderland each 7, Cardiff 6, Hull and Newcastle-on-Tyne each 5. Twelve deaths from whooping-cough were reported from West Ham, 10 from Salford, the remaining deaths being scattered over a wide area.

The number of stillbirths registered during the week was 279 (corresponding to a rate of 41 per 1000 births), including 42 in London.

The Services.

ROYAL ARMY MEDICAL CORPS.

Capt. H. J. Bensted to be Maj., and remains secd.

INDIAN MEDICAL SERVICE.

Temp. Capt. Piyare Lal Burman relinquishes his temp. commn.

LADY CHICHESTER HOSPITAL.—The last annual report of the Lady Chichester Hospital at Hove, Brighton, for cases of early nervous breakdown, states that the additions and alterations to the hospital have been completed. The hospital now contains 53 beds, which have all been occupied continuously ever since they were available, and in spite of the increased accommodation, the waiting list is always a very long one. This hospital, the first of its kind to be started in the British Isles, came into existence in 1905. It charges up to maintenance rate (£2 17*s.* 9*d.* per week for in-patients), according to the means of the patients, but no one is ever refused because of inability to pay, and many have been taken for nothing. There are two resident medical officers, and in addition to the honorary visiting physicians the hospital has a staff of consultants. The hospital is making an urgent appeal for funds to meet the £2000 overdraft on the building account and to enable it to carry on and extend its activities.

"Audi alteram partem."

THE SCOTTISH PRODUCTION OF LEARNING.

To the Editor of THE LANCET.

SIR,—In a recent address Prof. E. T. Whittaker, F.R.S., has made an analysis of 432 Fellows of the Royal Society with a view to finding how many of these were strictly Scottish. Of this number he found 47, or about 11 per cent., to be Scottish, the national element being strongest among the older Fellows. Of 86 Fellows who this year were 71 years of age or upwards, 17 were Scottish, a percentage which is nearly twice as great as that found among Fellows of all ages combined. Both quantity and quality were great. Of Fellows born in 1883 or subsequent years, there are between 40 and 50, but to the lecturer's surprise he has been unable to find among these a single Fellow of Scottish birth or education, and he held that the fact needs explanation. He dismissed at once the idea that there had been any falling off in the intellectual power of the Scottish race; his own experience of 17 years as an Edinburgh professor led him to say so. But he was inclined to find the cause in the nature of the education available in Scottish schools for boys of great natural gifts, the leading principle being to produce a high average all round, without making much provision for individual cases. The highly organised Scottish education had, he pointed out, a notably uniform character throughout, in marked distinction to education in England which was much less rigorously organised and presented a great number of different varieties of school and training. Thus in the Scotland of to-day a clever boy was compelled to keep step with the average boy, while in the older Scotland, as in the English schools at present, there was more flexibility. The consequence was, he said, that the English boy coming up as a freshman say, to Oxford or Cambridge at 18 would often know as much of his subject as an honours graduate of a Scottish University and the advantage gained in early years was never lost. The next campaign of reformers in Scottish education must, he thought, be essentially a campaign for greater individual freedom.

Prof. Whittaker's conclusions cannot be lightly set aside. It has all along been a feature of the Scottish Universities that the curriculum was broadly based and aimed at general culture rather than at specialised development. When "options" were established, there followed undoubtedly a confusion of values. But, apart from that, the resources of the Universities were spent mainly in equipment for teaching and not in equipment for research. But within recent years, certainly in the medical section of the Universities, research is assuming greater and greater importance. It has, however, always been an accepted understanding, marked, moreover, in the Arts subjects, that the more distinguished students of the Scottish Universities should aim at the Oxford or Cambridge curriculum, and large numbers of them have always done so, as the records of those Universities show. If the facts for all forms of scholarship, as well as for scientific scholarship, were scrutinised, I feel confident that Prof. Whittaker's proportions would not hold good. In this type of statistics, the conception of nationality is really not very relevant. But it must be allowed that, until recent years, the Scottish equipment for the higher sciences, as well as for the higher learning, has probably not kept pace with the best that has been done in certain Universities of England.

But I seem to see a new cleavage establishing itself even between English seats of learning. In philosophy, for example, London is taking a place that seriously rivals the best that Cambridge and Oxford ever occupied. But looked at internationally as well as nationally, Scotland, I think, continues to contribute her full share to all the higher intellectual studies. Prof. Whittaker's hint, however, deserves to be taken very seriously by the Scottish Universities.

Let me add another point: the brilliance of the Cambridge group of physicists, both past and present, is probably unique in the world. As the great sequence contained the names of Kelvin, Tait, and other Scotsmen, Scotland need not complain. But the challenge to our younger generation will no doubt have its effect. I am, Sir yours faithfully,

Feb. 14th, 1929. W. LESLIE MACKENZIE.

PROPHYLAXIS OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—In spite of the rapid advance of medical science in manifold spheres, pandemics and epidemics of influenza are still exacting a huge toll of lives and money throughout many nations of the world. Until the specific virus or other causative factor is discovered, our only hope of reducing the case-incidence lies in stricter measures of prevention.

In certain infectious diseases such as small-pox the law is empowered to fine anyone who knowingly suffering from the disease, by failing to take reasonable precautions for isolation, endangers the health of others. Similar steps might be taken during influenza epidemics to forbid patients leaving their homes while still in an infectious condition. No age or class is exempt from this disease, while a previous attack gives no protection. With so brief an incubation period as 24–48 hours, and so abrupt an onset, very little time is given for preventive measures to be applied. Keeping fit alone seems in itself an insufficient protection, as strong robust individuals often suffer more severely than the feeble ones. Vaccines have up to now met with very little success, and in any case would be impracticable for universal prophylaxis.

What, then, is our most potent weapon in the prevention of spread of this disease? Compulsory notification and isolation *in bed* of all cases suffering from influenza would soon put an end to direct infection through personal contact at work, in buses, theatres, churches, &c. Where this is impossible, hospitals should be thrown open for the nursing of severe cases of the disease, while public health centres should provide information on the antiseptic treatment of the nose and throat. All offices, factories, and shops should be circularised by the public health department of the locality advising the use of antiseptic gargles and tablets by their employees. Gauze masks impregnated with chemicals, though tried both in this country and America, have not come into general use owing to their unsightliness and the discomfort of wearing them for any considerable period.

I look forward in the near future to the time when no case of influenza will be permitted to wander out of doors until the period of infectivity is safely past.

I am, Sir, yours faithfully,

Penistone, Feb. 17th. ALFRED A. MASSER, M.B., Ch.B.

To the Editor of THE LANCET.

SIR,—I was greatly interested in Dr. Douthwaite's most helpful letter on the treatment of influenza. He gives us two specific—and I think most hopeful—lines of treatment: the use of serum and mercurochrome. I am convinced that the diet he suggests is the right one—fruit and any amount of fluid. Excess of food and solid food undoubtedly push the temperature up and tend to produce complications. My object in writing is to go a step further back—namely, what can we do in preventing patients taking influenza at all? In my opinion we have a most powerful weapon in correct prophylactic inoculation, and I cannot understand why this is not universally employed. The profession as a whole do not seem to have much faith in influenza prevention by vaccines—in my opinion one of the most certain things in medicine. In most cases the results are nothing short of dramatic. May I briefly describe my own experiences.

These experiences are based on my good fortune in the grave epidemic of 1918 in having been in charge of the influenza wards in a large military hospital, where I saw cases innumerable, and on 18 years in a large general practice with much school work. I have therefore had the advantage of seeing a very large number of cases. For ten years I have steadily practised the method of producing immunity by prophylactic inoculation, and I can without hesitation make the following definite statements :—

1. I have not seen a single death in an inoculated subject.
2. I have not seen a single complication in an inoculated subject.
3. I have seen many patients who were martyrs to severe and sometimes dangerous attacks of influenza once or twice yearly ; I have not seen one such case that did not respond to the vaccine used. I can recall one or two cases only where such patients had an attack after inoculation ; but such attacks were so mild and harmless as compared with their previous attacks that they gave no more cause for alarm than a cold in the head might. A little temperature and in two or three days they were perfectly well again.

Now for the other side : I had one failure—or partial failure. This was in a preparatory school of some 60 boys. These had been kept free for several years. On one occasion an uninoculated boy introduced influenza. Some ten of the inoculated cases became infected, but they took it so mildly that it was almost undiagnosable. I afterwards blamed my own technique that they took it at all, as I found I had given this batch half the dose of vaccine I should really have employed. Finally, until 1919, the headmaster of the school, a man of fine physique and excellent health, was subject to two attacks yearly ; these were of a serious nature. I inoculated him in 1919, and, though often exposed to infection, he went for some six years absolutely free. He then, during an epidemic, developed an attack. He was ill for 48 hours with one of the mildest attacks I have ever seen ; in a few days he was about again completely well.

If a patient develops influenza after inoculation—and I warn all patients that this is not impossible—the attack is so mild as to be almost negligible, and complications in my experience are unknown. Nor does post-influenzal debility follow.

I give two inoculations, at an interval of eight days, about the middle of October and again at the beginning of January. I have seen no reactions from this vaccine, which is prepared for me at the bacteriological department of St. John's Hospital, Lewisham, and consists of the following : In each cubic centimetre *B. influenzæ*, 200,000 ; *Micr. catarrhalis*, 250,000 ; pneumococci, 100,000 ; hæmolytic streptococci, 100,000 ; Friedländer's bacillus, 100,000 ; *Staph. pyog. aureus*, 500,000. First dose 0·2 c.cm. ; second dose 0·4, 0·5, or 0·6 c.cm. For extra security three doses may be given—0·2, 0·4, and 0·6 c.cm.

If a few medical men subject to severe attacks of influenza themselves would give this method a trial, I venture to say that prophylactic inoculation would soon become universal. I believe much depends on the vaccine used ; and two courses must be given during the influenza season.

I am, Sir, yours faithfully,

A. GRAHAM-STEWART.

Ulster-place, N.W., Feb. 15th, 1929.

ASTHMA RESEARCH.

To the Editor of THE LANCET.

SIR,—Notwithstanding Mr. Coke's disclaimer in the first paragraph of his letter, his second makes it clear that he does accept Dr. Culpin's and my own contention that he believes that all illness is somewhat disgraceful. I am, however, more interested in his third paragraph, which breaks new ground with its taking "the battle into the enemy's country"—the enemy being the psychotherapist. No doubt he intends a little banter, but at the same time he seems to feel he has scored over "the enemy" by curing a patient, by means of diet, who presented neurotic symptoms. It seems a pity to call those your enemies who should be your allies, and I should like to say that psychotherapists are not in the habit of thinking of those colleagues who study the physical reactions of the organism as hostile, nor hitherto have I thought that those physicians, who have asked for my help from the mental aspect, have thought of me as the enemy. Mr. Coke's own work on the physical aspect of asthma has always excited my admiration, and my personal acquaintance with some of his patients—whom, by the way, I had never treated—has convinced me of its soundness. But because he and others have relieved some illness or have shown that some symptoms are produced by physical means, we should not jump to the conclusion that those who believe that other illnesses are psychogenic and to be treated by psychotherapy are enemies. Even if we cannot have allies we might have neighbours. It is no new discovery that mental symptoms may have physical causes ; the toxic psychoses, general paralysis, and the mental symptoms of encephalitis lethargica may furnish examples, and have been known for some time. Certain conditions, on the other hand, such as the reflex paralysis of Babinski, which were at one time thought to be physical in origin, are now known to be mental. This discovery was made because of the joint work of neurologists and psychotherapists, and not as the result of warfare between them.

The distinction in meaning between the conceptions "psychogenesis" and "physicogenesis" is more difficult than Mr. Coke's expressions of opinion would imply. Psychogeny cannot be affirmed from the absence of physical reactions, neither of course can it be denied from their mere presence ; that the presenting symptoms are mainly nervous is no criterion. It is, however, the first statement that I wish to emphasise, for Mr. Coke seems to think that the diagnosis of psychogeny is made by those who cannot find any physical reason for symptoms. The conception does not depend in the least on negative findings. The diagnosis must always depend on findings which are at least as positive as those by which Mr. Coke obtains his brilliant results in certain cases of asthma. It would take too long to go into these diagnostic points here, but if Mr. Coke cares to receive it I shall be happy to send him a small contribution of my own on the subject.

Mr. Coke cannot understand why I should think he disbelieves his patients (I did not say *all* his patients), but if he will re-read his letters he will see that they do imply that neurotics are unworthy of credence ; surely his contention that the asthmatic when he was thought to be a neurotic was not believed implies that naturally no one would believe a neurotic. I am sorry that I am so dense or so ill-educated as not to understand the meaning of Mr. Coke's remarks about his thumbs, but I wish he would stop turning them downwards against the unhappy sufferers from neurosis.

I am, Sir, yours faithfully,

T. A. ROSS.

The Cassel Hospital for Functional Nervous Disorders, Penshurst, Kent, Feb. 18th, 1929.

To the Editor of THE LANCET.

SIR,—May I add another vertebra to the snake of correspondence which is wriggling its way through your columns ? The head of the beast was innocent enough ; it consisted of a letter signed by Eminent Persons saying that there is no single infallible cure for all cases of asthma. I myself would not care to put my name beneath such a statement—in THE LANCET because it is a platitude, in the lay press because readers might assume that such cures existed in other diseases.

It worried Mr. Coke too ; he wishes it to be known that there are cures for some and hope for all asthmatics. Unfortunately, in saying this, he says that in the past they have been classed as neurotics with small benefit to themselves ; so now, of course, he is catching it from the psychologists, though apparently he intended no attack on them and

though his words were true enough as used by ordinary men. If I may beg the question that hay-fever belongs to the asthma group, I should like to put on record that 19 years ago when I first started working at hay-fever, at least four out of every five patients had been told by their doctors that the disease was neurotic and that "if they did not think about it they would not have it"—they had therefore stopped going to doctors about it. We do not say this to them so often now—not because psychology has made advances, but because the grass pollen factor is too well known.

I believe firmly that all examples of the asthma syndrome—including Dr. Culpin's dermographia—are necessarily "psychogenic" in the sense that something psychological is essential to the mechanism of asthma, &c. But the psychologists have not proved very helpful. They demand the whole stage for their complexes which they consider the "main cause." Thus they fall into the same error as that which assails Mr. Coke when he declares that the "main cause" is the protein factor; for there are many many other "main causes" in the full make-up of the pathological mechanism of asthma.

Meantime the fact that a patient loses his asthma after the neat enucleation of a complex does not prove very much; they get well only too readily under the influence of any scientific bandobust.

I am, Sir, yours faithfully,

JOHN FREEMAN.

Devonshire-place, W., Feb. 19th, 1929.

To the Editor of THE LANCET.

SIR,—There is now little difference between the views of Mr. Coke and my own. The stigma originally affixed to the neurotic he extends to all imperfections of health, beauty, or strength, and though I might not support this thesis, yet I do not oppose it. His interest in cat phobia is welcome; whether any sensitiveness is demonstrable by skin reactions is just the kind of problem that calls for the coöperation of biochemists and psychologists. The phobia does not necessarily depend upon sight or smell, for I have seen it called up by a suggestion that the animal is present. Patients have said that the terror may precede conscious recognition of the presence of the animal, and this is perhaps related to the hyperæsthesia of some of the special senses that exists in such abnormal conditions as hypnosis and other states of dissociation. The patient feels the terror and is not aware of the sensory impressions that have called it up, but in the absence of some training in abnormal psychology this statement, though it must be accepted, is not easy to bring into accord with a priori ideas about mental processes. The behaviour of the cat phobia reminds us of authenticated cases in which hay-fever has been induced by the sight of an artificial flower. A well-known physiologist has described to me how the sight of a painting of a particular fruit brings on in him a mild attack of asthma, which he ascribes to a conditioned reflex.

One apparent difference does not exist. Mr. Coke "takes the battle into the enemy's country" and describes successful results of biochemical methods as if they contradicted some argument of mine. I have in this correspondence given full acknowledgment of the value of biochemical research, have favoured no particular therapy, and have not claimed ever to have treated an asthmatic.

I am, Sir, yours faithfully,

MILLAIS CULPIN.

Queen Anne-street, W., Feb. 17th, 1929.

URÆMIA SIMULATING ACUTE INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—Dr. Leslie Cole's interesting account in your issue of Jan. 19th (p. 128) of a case of uræmia simulating acute intestinal obstruction prompts us to summarise the notes of a case recently observed at Ancoats Hospital, Manchester.

A. B., aged 28, a goods porter, was admitted on July 3rd, 1928, in a comatose condition. The history obtained from the relatives was that he had started with colicky abdominal pain round the umbilicus on June 29th. The bowels had not acted since July 1st, and on the same day he commenced to vomit. Vomiting persisted, and on admission was fæculent. The abdomen was distended and visible peristalsis was observed. At this stage the blood-urea (urease method) was 240 mg. per 100 c.cm. The urine was dark and showed a few casts but no albumin. Later the cerebrospinal fluid urea-content (hypobromite method) was 350 mg. The comatose condition was so profound that death was considered imminent and operative interference useless. Improvement was shown, however, after intravenous saline and Mr. Hughes operated. Obstruction due to a band was found four feet above the ileocæcal valve, division of which resulted in the patient's return to consciousness on the following morning. An uninterrupted recovery followed. 9.7.28.—Blood-urea 40. 21.1.29.—Blood-urea 21. Urine showed no albumin or casts.

There is, in this case, no suggestion of mechanica interference with the urinary tract. The dramatic fall in blood-urea after operation practically negatives the possibility of a coincident nephritis, the presence of a few casts being the only evidence of renal damage, due, no doubt, to the general toxæmia. If the theory of deficient excretion can be put aside it becomes necessary to find some other explanation for the enormous rise in the blood-urea content. Our tentative suggestion is that this is to be found in an active hyper-production of urea by the liver, from the toxic intermediate products of protein digestion absorbed from the obstructed gut.

We are, Sir, yours faithfully,

M. LESLIE-SMITH, M.B., B.S. Lond.,
Pathological Registrar, Ancoats Hospital.

KENNETH HERITAGE, M.B., B.S., F.R.C.S.,
Feb. 18th, 1929. Resident Surgical Officer to the Hospital.

LOCAL ANÆSTHESIA IN UPPER ABDOMINAL SURGERY.

To the Editor of THE LANCET.

SIR,—Dr. W. Howard Jones's appreciative letter was of great interest to me from two points of view, as he has come to diametrically opposite conclusions to myself about the use of spinal anæsthesia.

He claims to have a large experience of injecting novocaine between the last dorsal and first lumbar spines, the region corresponding to the lumbar enlargement of the spinal cord. I cannot help thinking that he is fortunate not to have had any bad after-effects. A puncture of the spinal cord with a fine needle in itself is probably not a serious accident, but should one of the vessels be injured a hæmorrhage into the cord might easily take place and be followed by irreparable damage. Any surgeon who has exposed the cord by laminectomy will realise this possibility. When there is general anæsthesia as a safe alternative it is not worth the risk. Every puncture done for spinal anæsthesia should be made below the level of the spinal cord.

Dr. Howard Jones also maintains that for upper abdominal surgery spinal anæsthesia should be combined with general narcosis, and that intratracheal insufflation is the best method to adopt. I have the greatest dislike to a combination of general with either splanchnic or spinal anæsthesia for upper abdominal operating. I am not able to quote actual figures, but I have a very strong impression that pulmonary complications are, if anything, more frequent after operations performed under combined splanchnic and general anæsthesia than under general anæsthesia alone. If the tracheal insufflation is required it means that deep anæsthesia must be reached or the catheter will not be tolerated. Combined anæsthesia of this kind has all the disadvantages of general anæsthesia and none of the advantages of local anæsthesia.

As to the question of the spread of fluid in the spinal canal, it is against all the teaching of physical science to suppose that it is brought about by diffusion.

It is the simplest thing in the world to demonstrate that gravity does play a very important part in determining the position of an injected heavy fluid.

It is a great satisfaction to me to know that active work in spinal anæsthesia for higher abdominal operating is going on in several clinics in London.

I am, Sir, yours faithfully,

CHARLES A. PANNETT.

St. Mary's Hospital, W., Feb. 15th, 1929.

TRACHEAL INSUFFLATION.

To the Editor of THE LANCET.

SIR,—In his valuable article last week (p. 330), Dr. Howard Jones deserves commendation for drawing attention to a very important fact which is, I am sure, often overlooked by anæsthetists. What he terms "complete tracheal insufflation" is extremely difficult to obtain with most intratracheal apparatus, and the danger of the aspiration of fluids in mouth operations is a very real one.

For several years I have used a method of single intubation which does, I think, avoid all danger of the aspiration of fluids into the trachea. A single tube made of thin-walled but moderately hard rubber is passed (via the mouth or nose) into the trachea, and connected by suitable fittings to a bag made of rubber, which is of such a thickness that it is impossible to raise the pressure inside above 20 mm. Hg without blowing it up to at least four times its normal size.* The anæsthetic is supplied from a gas and oxygen apparatus. By keeping the bag very slightly distended I am able to maintain a constant, though never dangerous, positive pressure in the trachea, and so avoid all possibility of the aspiration of fluids. Moreover, this positive pressure overcomes any resistance to the passage of the respirations through the tube.

I am, Sir, yours faithfully,

STANLEY ROWBOTHAM.

Harley-street, W., Feb. 19th, 1929.

"THE BRITISH JOURNAL OF UROLOGY."

To the Editor of THE LANCET.

SIR,—We are writing to enlist your sympathy for our new venture, the *British Journal of Urology*, which will make its first appearance in March. It has long been a source of wonder to foreign observers that there should exist no British journal devoted to urology, which has become a universally recognised specialty, and is being taken up by an increasing number of young men in England to-day; whereas for a long time past journals of urology have appeared in America, France, Germany, Italy, and Spain. Since 1911 there has been an active British section taking part in the Congresses of the International Society of Urology. Again, and when the time was ripe, the Council of the Royal Society of Medicine thought fit to establish the subject of urology as a separate section, and not as a subsection of surgery, thereby showing that they held that urology was entitled to be separated off as a special subject for study.

We realise fully the generous help given hitherto by your journal in publishing a number of important articles on urology as practised in Great Britain; nevertheless, we feel that there is nowadays such a abundance of special work being done that can only find a voice if it can be given the additional outlet of a journal specially devoted to the subject. Such a journal is bound also to enhance the prestige of British urology. We feel sure, therefore, that our publication will in no way be hindering, but on the contrary will be supplementing, your efforts to forward the reputation of British medicine. A large editorial committee has been formed representing urologists in all the British-speaking countries of the world, and they intend, under our combined editorship, to bring out quarterly a British Journal of Urology (published by Messrs. Constable and Co., Ltd.), which will circulate not only in this country but in America and abroad.

The journal will publish original articles (freely illustrated), and full abstracts of the current urological literature. It will contain in each number a short practical article on common disorders of the urinary tract, calculated to help the general practitioner, notes on biochemistry, chemotherapy, and radiotherapy, and an up-to-date list of urological clinics, whereby foreign visitors to this country may find a ready guide to the clinics they wish to visit.

We are, Sir, yours faithfully,

FRANK KIDD,

H. P. WINSBURY WHITE,

Feb. 19th, 1929. Editors.

* The bag and fittings are supplied by Mayer and Phelps.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE LOCAL GOVERNMENT BILL.

ON Feb. 12th the House of Commons further considered the Local Government Bill on Report.

Provisions as to Alternative Powers of Giving Assistance.

Mr. CHAMBERLAIN (Minister of Health) moved an amendment to Clause 5 to provide that a council in preparing an administrative scheme should have regard to the desirability of securing that as soon as circumstances permit all assistance which could lawfully be provided otherwise than by way of poor relief should be so provided. He explained that the amendment carried out an undertaking he had given to put into this clause some indication of the Government's intentions, as the clause could not be made mandatory.

The amendment was agreed to.

Guardians' Committees and Subcommittees.

On Clause 7, para. 1, of which says: "In the case of a county the administrative scheme shall, unless the Minister for some special reason otherwise directs, provide,"

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) moved to omit the words "unless the Minister for some special reason otherwise directs." He said that as the clause was originally drawn it gave too wide a power to the Minister of Health and it might be argued that he could give a direction the effect of which would enable a council to vary any of the provisions of Subsection 1 of the clause. That was not the intention, and the amendment would make it clear that it was only in exceptional circumstances, and at the instance of the local authority, that the Minister could make an exception with regard to the appointment of guardians' committees.

The amendment was agreed to.

Sir KINGSLEY WOOD moved an amendment providing for the increase of the maximum number of members of the guardians' committees from 24 to 36. He said the Minister desired to utilise as much as possible the knowledge, personal influence, and touch of the members of the old boards of guardians, and the amendment was designed for that purpose.

The amendment was agreed to.

A Government amendment was also agreed to providing that a person should not be disqualified from being a member of a county or county borough council solely by reason of the fact that he or a member of his family had been maintained in an institution as a pauper lunatic.

Recovery of Expenses.

Mr. PETHICK-LAWRENCE moved to leave out Clause 15 which, he said, he regarded as the most dangerous and inimical to public health of any clause in the Bill. In the first place, it compelled local authorities to make a charge on all persons using their health institutions, with certain exceptions; and, in the second place, it fixed the amount that they must charge. That charge was to be deemed to be a sum representing the average daily cost per patient of the maintenance at the institution and the staff thereof, and the maintenance and the treatment of the patients therein. He had made some investigations as to what those sums amounted to in the case of the voluntary hospitals in London, and, omitting some of the charges which he thought would be excluded by these words, he reckoned that they would run from £2 5*s.* or £2 10*s.* a week per patient in the case of a maternity home to £4 5*s.* or £4 10*s.* in the case of a cancer hospital. Not only was the charge to be made on the patients themselves, but if the patient could not pay all the persons upon whom a patient was regarded as dependent could be called upon for payment.

In maternity cases the charge would not be for more than two or three weeks, but in certain illnesses, notably cancer, it might run to three months and the charge therefore would be about £50. The chief exceptions were those relating to infectious disease. He understood that no actual definition of infectious disease had been included in the definition clause, and that the Ministry of Health held that the term would include what was commonly known as infectious disease to doctors and also venereal disease and pulmonary tuberculosis, but that it would exclude certifiable tuberculosis. As had been pointed out on the Committee stage, this provision as it stood would mean that a labourer earning £2 a week who had contrived to save £40 or £50 in the course of his life might have all those savings taken to cover the charges, say, for his wife's treatment in a cancer hospital. The effect would be that numbers of working people, realising this state of affairs, would go to any lengths to avoid entering an institution. Therefore it was not merely a question of the hardship involved to these people; it was also a question of the grave detriment to public health which would arise if the clause was carried in its present form. The Minister had so far realised the force of the objections raised that he had given notice of an amendment which would enable local authorities not to charge the full bill not merely when they were satisfied that the patient or his relatives could not pay it, but also when they thought it unreasonable that they should pay it. That was a great advance on the clause as it stood, but it was still insufficient. He still thought that to include in the cost of maintenance a sum representing the average daily cost per patient of the maintenance of the institution and staff thereof and the maintenance and treatment of the patients therein was too wide a definition. It covered in the case of a cancer hospital very expensive treatment and apparatus. In the second place, he very strongly objected to the wide area of relatives brought into the purview of this proposal. He would lay special stress upon the case of the unmarried mother. In the interests of public health and the future generation they had learned that it was desirable that any illegitimate child should come into the world so far as physical means were concerned with the very best chance for its own life and for the good of the community. It had been found by all the institutions which catered for maternity cases that it was most undesirable to insist upon the relatives knowing the facts with regard to an illegitimate birth. The provisions of this clause in this respect, therefore, would be highly undesirable from the point of view of public health. Illegitimate children would be born under most unsatisfactory conditions. In many cases attempts would be made to get rid of the child. If the Government could not agree to delete the clause he hoped that the House would not be contented with the proposed amendment of the Minister of Health but that something further would be done to meet the objections he had raised.

Sir KINGSLEY WOOD said that the reason for the insertion of this clause was the alteration which was being made by the transference from the guardians of their institutions to the larger local authorities of the country; and unless there was a clause of this kind in cases of poor-law administration the local authority would be under an obligation to charge a pauper for treatment, while in cases of institutions where people did not come under the operation of the poor-law the local authority would have no such duty cast upon them. How could one reasonably say that such a clause was detrimental to the public health? It was a clause in keeping with the English character and qualities and one which the people themselves would desire. Mr. Pethick-Lawrence had said that the net was spread too wide, and that they were trying to make too many people responsible for the unhappy person who had received treatment. That was a criticism not of the clause but of the existing law. The Poor-Law Act, 1927, Section 41, exactly defined the liability to relieve and maintain relatives. Was that an excessive duty, or one of which the average person could complain, if he were just and wanted to do his duty to himself and his family? There was no ground for the fears of the hon. Member in regard to the unmarried mother. There was not a maternity home in the country, municipal or voluntary, which did not make a charge for their patients. Anyone who considered the clause in a reasonable spirit, apart from political partisanship, knew that it really embodied what was the practice of the voluntary hospitals.

After further debate,

Dr. VERNON DAVIES said that as a medical man with some experience he hoped he would live long enough to see the treatment of disease according to need and not according to the financial capacity of the patient, and to see the break up of the poor-law. But they had been assured by the Minister of Health that at present the time for that was not ripe; that it would be impossible for this Bill to function and at the same time to break up the poor-law. So they had the position that under the poor-law the destitute poor or their relatives could be charged by the local authority a certain amount for their treatment and maintenance and that, on the other hand, the people who were not poor who were treated under the Public Health Act could escape free. That was a very alarming position which undoubtedly penalised the pauper. They would all have liked to have got rid of the pauper charge if they could, but not being able to do that—and he accepted the Minister's words whole-heartedly on that point—and as it was not possible even to put all sickness for the time being on the same level, the Minister was making a charge for everybody according to their means. There was to be no increase of the present charge according to the poor-law; they were to go on as they had been going on for many years. He had for many years experience in an industrial practice and he had very often the experience of patients who had to go to voluntary hospitals and also to the poor-law hospitals. Never in the whole of his experience had he come across a case where any complaint had been made by patients or relatives of undue charges for hospital attendance, either in the poor-law hospitals or the voluntary hospitals. The circumstances of the patient were taken into account, the circumstances of the relatives were taken into account, and his experience had been that the people when they came out were very grateful for what had been done to them. That was not going to be altered by this Bill. The Labour Party were, perhaps, unduly apprehensive of the dangers of this clause. They seemed to think that people would be afraid to go to the hospitals on account of the charge. When people were ill money did not count. Treatment came first and they went to the hospitals and were only too glad to get there. He could not understand why members of the Labour Party should have the idea that the Government, the hospital authorities, and the guardians of the poor were simply out to rob the poor of all they could. The suggestion was that the charge they were going to make, legally or illegally, was so high that the people would be terrified to go into hospitals on account of that charge.

Mr. PETHICK-LAWRENCE: The hon. gentleman is not entitled to make any allegation of that sort. The great object of our amendment is to leave the local authorities and the public health authorities in the locality with the option. Our objection is that this clause takes away the poor-law option and imposes upon them a definite course of action which we think is undesirable.

Dr. DAVIES said that he was referring to the statements which had been made by members of the Labour Party. With a fairly long experience he had not known these things happen up to the present under the poor-law and therefore he failed to see why it should be imagined that they would happen in future. He had more trust in the people of this country and in the guardians than to believe that they would allow people to be badly treated. He was sure that this clause would be of great benefit to the people.

The amendment was negatived by 221 votes to 114.

On Feb. 13th the House further considered the Local Government Bill on Report.

Town-planning.

On Clause 38 (Power of County Councils to act jointly with other local authorities in preparation or adoption of a town-planning scheme),

Mr. CHAMBERLAIN moved a new subsection extending the clause to the County of London. He said that the London County Council was already a town-planning authority, but it was desirable that it should have the power to act jointly with other councils in regard to town-planning.

The amendment was agreed to.

Mr. HARRIS moved an amendment to provide that local authorities should be required to prepare town-planning schemes by Dec. 31st, 1930, instead of Jan. 1st, 1939, as provided in the Bill.

Sir KINGSLEY WOOD said that they were all anxious to see town-planning put into force as rapidly as possible, but they had to consider how soon local authorities should be forced to bring forward town-planning schemes. Above everything else they wanted good town-planning schemes rather than quick ones.

The amendment was negatived by 218 votes to 129.

On Feb. 15th the House further considered the Local Government Bill on Report.

Superannuation of Transferred Poor-law Officers.

On Clause 114 Sir KINGSLEY WOOD said that at a conference recently held between the Minister of Health and the representatives of the officers the matter was discussed. It was the desire of the Government to treat these officers justly and fairly and as a result of the conference he now proposed to move an amendment. This allowed the existing officers to elect to remain under the Poor-law Officers' (Superannuation) Act 1896, even although their new employers might have a superannuation scheme under the Local Government and Other Officers' (Superannuation) Act, 1922, or any local Act. By agreement this option was limited with the result that if Parliament should

ake provision for the extension of the Act of 1922 to all unties and county boroughs which had no local Acts, then e officers would all come under the Act of 1922.
The amendment was agreed to.

Power to Remove Difficulties.

Sir H. SLESSER moved to leave out Clause 120. He said at on the Committee stage there was considerable objection the power which the Minister of Health sought to take—mely, that when what the Minister thought was a fficulty over the Bill arose by Order he might remove make any appointment, or do any other thing which peared to him necessary or expedient and that such an der might embody the provisions of the Bill. When rliament had set a limit to a particular Act it was in inciple most dangerous and inexpedient to give to a inister or a Department power to vary that Act even with e protection that they were compelled to lay the Order bsequently on the table of the House. The question at ue was whether it was in the interests of the State that inisters should be given the power to alter an Act of rliament without any definition of the limitations of those erations.

Mr. CHAMBERLAIN said that these powers were not for e exaltation of the bureaucracy in order that they might terfere with the intentions of Parliament. They were wers asked for in the general interest of the public to get er difficulties which had not, and very likely could not, ve been foreseen, but which would hold up the working the Act in particular places and on particular occasions. e clause had only a limited period of operation and could t go on after Dec. 31st, 1930. There was nothing at all constitutional, arbitrary, or dictatorial in the mind of the vernment, or of those who would have to apply the words the clause hereafter.

After further debate Sir H. SLESSER's amendment was gatived by 207 votes to 119.

Sir KINGSLEY WOOD then moved to leave out the words the clause "may by Order remove the difficulty or make y appointment or do any other thing which appears to m necessary or expedient for bringing the said provisions to operation," and to insert the words "make such der for removing the difficulty as he may judge to be cessary for that purpose."

The amendment was agreed to.

The Report stage of the Bill was concluded.

The Third Reading of the Bill.

On Monday, Feb. 18th, Mr. CHAMBERLAIN, in moving the ird reading of the Local Government Bill, said that he uld not remember any measure comparable with this length, in importance, in complexity, embodying so any diverse features, and vitally affecting so many portant interests, which had come through its various ages in that House with so little alteration. Nobody who d listened to the debates would dispute for a moment at the discussions on maternity and child welfare services, e future of the poor-law, the administration of the ansferred functions, the working of the formula, and other atters, had been most illuminating, and if the amendments hich had resulted had not gone down to the roots of the ll it must be admitted that they had been extremely luable both as defining more closely what were the tentions of the Government and as illustrating more ecisely what was likely to be the effect of the Government's oposals. On the second reading of the Bill he had umerated five outstanding defects of local government hich this Bill was designed to remedy. No single voice d challenged the existence of those defects and no single rty had challenged the fitness of the remedy which the vernment were seeking to apply to the first three of em—the administration of the poor-law, the responsibility for the maintenance of highways, and the power that was ven to county councils to review the boundaries and the ture and the character of the authorities which governed county districts. The first five parts of the Bill, comning more than half the total number of clauses, appeared day almost as they were when the Bill was introduced. e formula had one advantage which no amount of oretical casuistry, or cheap mockery about sums in mentary algebra, could take away from it—if worked. put the money where they wanted it to go. He was tain that this formula was going to provide local authorities h ample funds for their services, including health services, l particularly those services which were concerned with thers and children, which must be extended. He coupled h those services the voluntary associations to whom power s now given to make representations to the Minister if y found that local authorities were backward in giving services for which their resources had been extended. wer had been given to the Minister under Clause 94 to ng up the standard of backward or recalcitrant authorities. this scheme they had a measure which was not only not ng to stifle or cripple the local services, but which was going to prove a jumping-off ground for a fresh leap forward in the standard of health and welfare of the community throughout the country.

A Labour Amendment.

Mr. ARTHUR GREENWOOD, on behalf of the Labour Party, moved the following amendment:—

That this House declines to assent to the Third Reading of a Bill the most important provisions of which have not received adequate parliamentary discussion and which, purporting to stimulate trade, secure reforms in local government, and regulate the financial relations between the State and local services, ignores the fundamental remedies for trade depression, and is unacceptable to local authorities on account of the confusion it will create in the realm of local government, its failure to accept national responsibility for burdens wrongfully imposed locally, its provisions for relieving some ratepayers at the expense of others, and the effect it will have in degrading the standard of the social services and crippling their development through the impoverishment of local resources and a system of State grants based upon a false national economy.

He said that as a measure of local government reform the Bill was pettifogging and partial. It did not cover the ground and it would lead to other problems of local government which would have to be solved in the future. It would leave far more disaster behind than blessings in its train.

Mr. PETHICK-LAWRENCE, in seconding the amendment, said that in one street there might be a brewery, a hospital, and a shop. The Bill would give relief to the brewery, but none to the hospital or the shop.

After further debate,

A Medical View.

Lieut.-Colonel FREMANTLE said he desired to sum up the use and value of this measure to public health and local government services with which he had always been associated. He expressed surprise at many of the criticisms made from the other side of the House. With some of those criticisms he had the greatest sympathy. He knew the difficulties of a reform of this sort, but some of the criticisms were surprising when one remembered the way in which from all sides the progressive forces were working in this very direction 20 years ago. He was, at that time, not only a medical officer of health, but a prospective candidate for Parliament. He had the advantage of belonging to a committee of the Unionist Party in that House, which brought in one or two co-opted Members from outside to help and advise them. That committee included one future Lord Chancellor, one future Parliamentary Secretary of the Ministry of Health, and the present Prime Minister. The secretary of the committee was a very remarkable man, who unfortunately never attained to membership of the House of Commons, but who did wonderful work in his own line. He was a man of great chivalry and originality, whose death was announced in that day's papers—Mr. Maurice Woods, the son of the late Master of the Temple. After very hard work the committee produced a report. As the war had broken out he (Colonel Fremantle) was abroad when the report was presented, and he only saw it when he returned from the war. The report dealt with the poor-law situation and tried to get a practical *via media* between the Majority and the Minority Reports of the Poor-Law Commission. It dealt especially with the proposals as they affected public health. He was surprised to find, on looking at that report the other day, how the present Bill brought, to a very large extent, into force exactly the same measures which were then advocated with very considerable temerity and difficulty because of the novelty of the subject. From the point of view of public health he took it that when they were going to have a measure of definite de-rating relief for productive industry it was really intended to help productive industry. Those who believed in that recognised that that went at once to the root of public health, because nothing so much affected the health of the nation as its material prosperity, apart from its moral and spiritual prosperity, which they were not discussing in that Bill. Agriculture was of value from the health point of view, because it was the basis of the country life, and it would be of very material help that £6,000,000 was definitely given to agriculture. After all, the poor-law, which was the chief administrative subject changed in the Bill, was the first main provision for public health made by Parliament in this country. With its institutional and outdoor relief it gradually developed a medical system of attendances free to every man, woman, and child, and it was unfortunate that as that system developed and the time became ripe for a further advance in local government, that parties on both sides of the House rejected the proper evolutionary way of developing the health services. Instead of continuing their health services on the poor-law system, they set up a new system of urban and rural district councils. In the past 40 years public health had been faced with the difficulty of a multitude and tangle of different authorities, which had inevitably meant much inefficiency, weakness of resource, and dissipation of

attention and energy. Medical officers of health who were concerned in trying to carry out health measures saw the enormous resources of the poor-law institutions, from which they were cut off and with which they could have nothing to do; the outdoor domiciliary attendance, with which they could have nothing to do; the system of vaccination, and medical attention of one kind or another. The first thing they would have wished for would be the consolidation of those measures. Members of the Opposition had suggested that the Bill was no improvement, but would lead to confusion. That was an absurd suggestion. It was certainly not a final solution of the problem, but it was going in the right direction, and in the gentle manner in which English reform always found its way. It first put the poor-law into the hands of the county councils, and how Members opposite, who really understood the subject, could suggest that that was wrong he did not know. At the same time they were coördinating in many ways the work of the county councils with that of the local sanitary authorities. He attached a very great deal of value to the powers given in the Bill for the reconsideration, overhauling, and systematisation of the schemes for dealing with infectious diseases, the water-supply, and sewage disposal throughout the country. It was inevitable that for those interested in these things there were one or two points on which they were still not entirely satisfied. In a measure of this complexity there must be some minor points which remained to be settled, and he hoped that further amendments would be made in the House of Lords dealing with points which had been left undiscussed owing to the operation of the guillotine resolution. The progress outlined in this Bill was in the direction of systematisation, and he thought that the objections which had been urged to that systematisation were rather absurd. He disputed the view of the legal profession that everything must be laid down by Act of Parliament. It was necessary that the Minister should have some power to make rules and interpret the measure. He hoped, however, that some scheme might be devised by which Orders laid on the table of the House could be brought to the notice of Members, in such a way that they would be bound to take notice of them.

The Value of Coöperation.

Mr. GATES said that when he criticised the Bill before he did so on the ground that he was afraid that the maternity and child welfare services would suffer if they were put upon the block grant system. He confessed that a great many of the voluntary associations were still not quite easy in their minds, but they were a great deal easier since certain amendments had been inserted in the Bill by the Government. He was not afraid from the point of view of health of what was called the reign of bureaucracy in Whitehall. The voluntary associations which had done so much work in connexion with public health services would have much preferred that the maternity and child welfare services should still have been left on the percentage grant system for the original term of seven years, if that had been possible. He was, however, glad to hear from the Minister that he shared with him, and most of those who were interested in maternity and child welfare, their admiration for the coöperation of the voluntary associations with the officials. The coupling of the enthusiasm of those associations with the work of the officials had been of enormous value to public health. He knew that the Minister attached more importance to Clause 94, which was a punitive clause, than he, or the voluntary associations, did. It was a clause which he was afraid could only be used in very rare cases to speed up a laggard authority to a mere minimum of health services, and then only when the Minister was satisfied that the Council was failing to maintain a reasonable standard of efficiency and progress having regard to the standard maintained in similar boroughs. The voluntary associations could not help being afraid that many councils would prefer to use the block grants for the purpose of reducing their rates rather than for promoting these services. He thought this was an unfounded fear, and that the Government's amendments would reduce the grounds for such a fear to a minimum.

Reply to the Debate.

Sir KINGSLEY WOOD, replying to the debate, said that one of the most unfounded criticisms of the Bill was that which found a place in the Labour Party amendment—namely, that the proposals of the Bill would degrade the standard of social service in the country. The discussion on block versus percentage grants had amply demonstrated that there was hardly anyone who was prepared to stand up wholly for the present percentage grant system. A most welcome fact had been the considerable change of opinion among people who were particularly interested in the maternity and child welfare service proposals of the Bill. It had been more and more appreciated that the present system benefited the rich areas and handicapped the poor areas, and that there was no effective power vested in the Minister of Health to bring about a better state of things in the case of an authority that was not properly discharging its health duties and functions. The debates on this Bill had clearly demonstrated that the new system would at any rate remedy many of those grave defects.

The Labour amendment was rejected by 292 votes to 113, and the Bill was then read the third time.

HOUSE OF LORDS.

TUESDAY, FEB. 19TH.

AGE OF MARRIAGE BILL.

Lord BUCKMASTER moved the second reading of the Age of Marriage Bill, which seeks to make void marriages between persons either of whom is under the age of 16. He said that the measure was intended to remove a great disgrace on our laws, and to put our position in regard to marriage on the same basis as some of the more advanced countries in this respect. By the law of this country it was possible for marriage to be validly solemnised, with the necessary consent, between a girl of 12 and a boy of 14. The reason that was given for this age in the ancient text-books was as follows: "It is not because the parties are supposed to have sufficient discretion to appreciate the consequences of so critical and responsible an engagement, but because in general they at that time arrive at physical maturity and the worst social evils will ensue from holding them incapable of marriage." Everybody to-day recognised that to enable children of 12 and 14 to undertake what everyone regarded as the most solemn responsibility of life was a thing almost entirely contrary to our good sense. It was at this moment a criminal offence for a man to have relations with a girl under the age of 16. She was incapable of consenting. Was it not a remarkable thing that what a girl was not capable of consenting to once she could consent to in perpetuity, and that by law she was enabled to protect the man from his criminal action by the mere process of going through the ceremony of marriage? It might be that the number of such marriages was small, but that had nothing whatever to do with it.

The Marquess of SALISBURY (Lord Privy Seal) said that the Government were willing to accept the Bill.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 13TH.

Replacement of Surgical Boots.

Mr. THURTLE asked the Minister of Pensions if there was any fixed period that surgical boots provided by the Ministry had to last before they could be replaced by new ones.—Lieut.-Colonel STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: Surgical boots are issued in duplicate and while each pair is expected to last two years they may be replaced at an earlier date if worn out by fair wear and tear.

The Sale of Aspirin.

Sir ROBERT THOMAS asked the Minister of Health whether he was aware that there was a movement to instal automatic machines for the sale of aspirin; and whether his advisers were of opinion that such uncontrolled sale of this drug was in the public interest.—Sir KINGSLEY WOOD replied: I understand that this question has been referred to the Inter-Departmental Committee on the Poisons and Pharmacy Acts, and my right hon. friend must await their report before expressing any opinion upon it.

Sir W. SUGDEN asked if the right hon. gentleman was aware that aspirin was being widely advertised and sold as "Aspro" without a label in small pennyworths in little shops throughout the country.

No further answer was given.

Assessment of Voluntary Hospitals.

Sir NICHOLAS GRATTAN-DOYLE asked the Minister of Health whether his attention had been called to the increased assessments under the Rating and Valuation Act, 1925, on provincial voluntary hospitals; and whether, in view of the public service rendered by these institutions and of their financial position, he would consider either derating them or giving them preferential terms of assessment.—Sir KINGSLEY WOOD replied: As my right hon. friend has previously explained, the exemption of hospitals from rating could not be effected without legislation, and he does not consider that such a proposal can be considered apart from the similar claims made on behalf of other charitable and public institutions. The same considerations apply to preferential terms of assessment. The Central Valuation Committee has made certain recommendations with respect to the assessment of hospitals and charitable institutions and where these have been adopted there should be no undue hardship.

Sir N. GRATTAN-DOYLE: Will the right hon. gentleman consider the desirability of introducing legislation to cover all those points which he has mentioned?

Sir KINGSLEY WOOD: I am sure we all desire to do what we can for the voluntary hospitals, but the hon. Member will no doubt realise that if one began to give preferential treatment in this way to voluntary hospitals one would immediately be confronted with claims on behalf of institutions for the blind and other institutions. This raises a very big and important question which it is hardly possible to deal with by way of question and answer.

Opium Traffic at Hong-Kong.

Mr. PONSONBY asked the Secretary of State for the Colonies whether, in view of the statement made to the League of Nations Opium Commission at its recent session by the British representative regarding the excessive consumption of opium at Hong-Kong, he could state what measures were being taken by the Government of Hong-Kong to restrict the consumption, and what reasons it gave for its failure.—Mr. AMERY replied: As was explained by the British representative in his statement to the League of Nations Advisory Committee the excessive consumption of opium in Hong-Kong is due to the large quantities of smuggled opium which pour into the Colony from China. The Colonial Government has established a legal Government monopoly of the sale of opium with the intention of restricting consumption by charging high prices for Government opium. That monopoly, however, is not effective because, in spite of an energetic preventive service which seizes large quantities of illicit opium and the punishment of large numbers of offenders by fines and imprisonment, it has been impossible to prevent the smuggling on account of the abundance of cheap opium in China and the facilities for illicit traffic provided by the close proximity to and regular intercourse with Chinese territory. Primarily in the hope that it will suggest a means of solving the extremely difficult problem in Hong-Kong, His Majesty's Government suggested last year that the League of Nations should send a Commission of Inquiry to investigate the opium problem in the Far East and the League have agreed to do so.

THURSDAY, FEB. 15TH.

Review of Final Pension Awards.

Sir WALTER DE FRECE asked the Minister of Pensions in how many Great War pension cases final awards were reviewed during 1928, and with what results.—Major TRYON replied: During the period referred to about 1300 cases (including cases of re-amputation and second disabilities) have been reviewed and have received a further grant under special sanction.

Health of the Mercantile Marine.

Dr. VERNON DAVIES asked the President of the Board of Trade, if the joint advisory committee set up by the Board of Trade and the Ministry of Health had been given power to recommend fresh legislation under circumstances where this might appear to them to be necessary.—Sir P. CUNLIFFE-LISTER replied: The Joint Advisory Committee of the Board of Trade and the Ministry of Health have power to advise on any question affecting the health of the Mercantile Marine that either department may refer to them. There is nothing to prevent the committee from making proposals involving fresh legislation on any such question, if such a course appears to them to be desirable.

First Aid in Road Accidents.

Mr. HAYES asked the Home Secretary on what agencies the police relied in dealing with road accidents in the Metropolitan police area beyond the London County Council district and outside the area of the activities of the Red Cross ambulance services; and whether the police were experiencing any difficulty in the expeditious removal of injured persons to hospitals.—Sir WILLIAM JOYNSON-HICKS replied: The police make use of the ambulances of over 50 different agencies, including the St. John Ambulance Association, 42 urban district councils, and 13 borough councils, and it is only in very rare cases that any difficulty occurs in arranging for the expeditious removal of injured persons to hospital.

Clearance of Insanitary Areas.

Sir ROBERT GOWER asked the Minister of Health what schemes for the clearance of insanitary areas had been sanctioned by him during the 12 months preceding the 1st Feb., 1929, and the dates upon which such schemes, respectively received his sanction.—Mr. CHAMBERLAIN replied: The following statement gives the local authority and the date of confirmation in 1928:—

Chelsea M.B.C. (World's End Passage area): March 15th. Leeds T.C. (West-street area): April 18th. Sheffield T.C. (Lambert-street, Furnace Hill and Scotland-street area): May 7th. Knaresborough U.D.C. (Hope-street): July 5th. Wednesbury T.C. (Hall End): August 1st. Brampton R.D.C.: Aug. 13th. Preston T.C. (Poplar-street, &c., area): Sept. 14th. Rochdale T.C. (Richard-street area): Sept. 22nd. Exeter T.C. (No. 4 area, Section A): October 19th, Liverpool T.C. (Queen Anne-street): Nov. 23rd.

Duties on Radium Compounds.

Mr. WEDGWOOD BENN asked the Secretary to the Treasury whether he could state, for any convenient period, how much money was collected in duties on radium compounds prior to the temporary suspension of the tariff.—Mr. A. M. SAMUEL replied: The amount of duty recorded as collected in respect of radium compounds imported during the 12 months prior to May 15th, 1928 (i.e., the date on which the temporary suspension of the duty took effect) was £32.

Open-air School Classes.

Sir ROBERT THOMAS asked the President of the Board of Education how many open-air classes have been regularly held in London schools during the year 1928; how many children attended them; how did the attendance percentage compare with that of indoor classes, and what were the chief results observed as regards health.—Lord EUSTACE PERCY replied: 167 classes were conducted during the period. No separate records of attendance are available, but it appears to have been at least up to the average. The children are reported to have gained in health and mental alertness.

The Training of Midwives.

Mr. HANNON asked the Minister of Health whether he was aware that the Central Midwives Board had directed that pupil midwives at the two hospitals of the Birmingham guardians should cease to take their theoretical instruction within those hospitals; that those hospitals had highly qualified medical officers with ample experience in the training of midwives and were equipped with every modern facility; that the guardians of the Birmingham Union had expressed opposition to the proposed change which involved needless expenditure of public money and unnecessary expense to those receiving instruction; and if the Minister would recommend to the Central Midwives Board the propriety of withdrawing their direction pending the report of the departmental committee which had been appointed to consider the whole system of the training of midwives.—Mr. CHAMBERLAIN replied: I am aware generally of the position as stated in the first three parts of the question. This is, however, a matter in which I have no authority to interfere with the discretion of the Central Midwives Board, and I have accordingly not taken the action suggested in the last part of the question.

Mr. HANNON: Can my right hon. friend think out any means whereby he can prevent such autocratic action being taken by this Board?

Mr. CHAMBERLAIN: A departmental committee is considering this matter, and a question of this kind will, I think, come within the terms of reference.

London Lock Hospital.

Mr. PETHICK-LAWRENCE asked the Minister of Health whether he has now received the report of the committee appointed to inquire into the London Lock Hospital, and whether it was his intention to have it published.—Mr. CHAMBERLAIN replied: I have received the report and am in communication with the Governing Body of the hospital with regard to it. In the meantime I propose to reserve my decision on the question of publication.

MONDAY, FEB. 18TH.

Silicosis in the Pottery Industry.

Mr. HOLLINS asked the Home Secretary whether any date had been fixed for the issue of the draft regulations for amending the present regulations in the pottery industry, as recommended by the departmental committee appointed to consider a scheme of compensation for silicosis in the pottery industry, and what were the reasons for the delay in issuing the draft regulations.—Sir W. JOYNSON-HICKS replied: The issue of these regulations has been postponed pending the report of the committee which I appointed in December last to inquire into the medical arrangements for diagnosis of silicosis. It is essential that before attempting to deal with this question I should have the report of the medical investigation.

The Cocaine Traffic.

Mr. ROBERT MORRISON asked the Home Secretary the number of convictions during the past 12 months for illegal possession of cocaine and similar drugs, and whether this traffic had now decreased.—Sir W. JOYNSON-HICKS replied: The statistics in question are not yet available. While it is not possible to speak positively in a matter of this kind, the experience gained in the administration of the Dangerous Drugs Acts indicates that the illicit traffic in these drugs has very much diminished in this country since the institution of Control.

Disease in Imported Sheep Carcasses.

Mr. WILLIAM THORNE asked the Minister of Health approximately how many sheep had been examined and

the proportion condemned for caseous lymphadenitis since Sept. 1st, 1928, with the exception of imported mutton from New Zealand, by the municipalities of the city of London, Liverpool, Bristol, the county borough of Southampton, and the metropolitan boroughs of Southwark and Finsbury, respectively.—Sir KINGSLEY WOOD replied: The following is the information asked for: The numbers of sheep carcasses examined by the local authorities mentioned and the numbers condemned by them for caseous lymphadenitis since Sept. 1st, 1928, with the exception of imported mutton from New Zealand were as follows:—

	Examined.	Condemned.
City of London	125,140	12,099
Liverpool	54,668	3,336
Bristol	100	2
Southampton	2,131	70
Southwark	75,274	3,491
Finsbury	27,000(approx.)	2,003

These figures are made up to various dates from Jan. 31st onwards.

Town-planning in London.

Mr. HARRIS asked the Minister of Health when he received a request from the London County Council that the provisions of Part III. of the Local Government Bill dealing with town planning should not apply to London.—Sir KINGSLEY WOOD replied: Clauses 40–42 cannot in any case apply to London. As regards Clauses 38 and 39 my right hon. friend caused inquiry to be made after the proceedings in committee and ascertained from the clerk to the County Council that, while the application of Clause 38 to London raised no difficulty the application of Clause 39 was not likely to be acceptable to the County Council. The Bill was amended accordingly on report. Owing to the urgency of the matter there was not time to bring it before the Council.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation on Feb. 16th the following degrees were conferred:—

M.B.—E. G. Recordon.

B.Chir.—I. C. C. Tchaperoff.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary meeting of the Council of the College on Feb. 14th with Sir Berkeley Moynihan, the President, in the chair, Mr. R. P. Rowlands was appointed Bradshaw lecturer for the ensuing year and Mr. E. W. Hey Groves Hunterian Orator for the year 1930.

A letter was read from Sir James Berry resigning his seat on the Council, such resignation to take effect in June next. Sir James Berry's resignation was accepted with regret.

It was reported that an election of four Fellows to the Council will take place on Thursday, July 4th, to fill the vacancies occasioned by the retirement in rotation of Sir Holburt Waring, Mr. C. H. Fagge, and Mr. W. Sampson Handley, and by the resignation of Sir James Berry. Notice of the election will be given to the Fellows by advertisement and by circular on March 9th; March 18th will be the last day for the nomination of candidates and a voting paper will be sent on April 2nd to every Fellow of the College whose address is registered at the College.

It was further reported from information recently received from Canada that it appeared probable there would be a sufficient number of candidates to justify a primary examination for the Fellowship being held at Toronto this year, that the dates of examination had provisionally been fixed for August 6th and 7th for the written and August 9th and 10th for the viva voce examination, and that Profs. William Wright, W. E. le Gros Clark, C. Lovatt Evans, and John Mellanby had accepted the nomination to conduct the examination.

The diploma of Fellow was conferred upon Mr. Russell Claude Brock, Guy's Hospital, who has now complied with the by-laws of the College.

Diplomas in Public Health were conferred jointly with the Royal College of Physicians upon the candidates whose names were given in our issue of Feb. 9th (p. 317).

Diplomas of Member were conferred upon 143 candidates (including 15 women) who have passed the requisite examinations and have complied with the by-laws of the College. The names of these candidates are the same as those printed in our issue of Feb. 9th, in the list of Licentiates of the Royal College of Physicians, with the exception that H. Bernstein, M. K. Gyi, J. F. V. Lart, A. S. Rajasingham, B. W. Rycroft, and Florence Whitrow have previously received the Diploma of Member.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the College was held on Feb. 5th, with Dr. R. A. Fleming, the President, in the chair.

Dr. James Davidson Stuart Cameron and Dr. Archibald Nathaniel Shirley Carmichael were introduced and took their seats as Fellows of the College. Dr. Ella Ferrier Pringle and Dr. John Miller Woodburn Morison were elected to the Fellowship.

Dr. William Sidney Thayer, Emeritus Professor of Medicine of the Johns Hopkins Medical School, Baltimore, U.S.A., was appointed Gibson Lecturer for the triennial period, 1929–31.

HUNTERIAN SOCIETY.—The members of the Hunterian Society and their guests assembled at the Mayfair Hotel, Berkeley-street, W., on Feb. 14th, Dr. A. Westerman, the President, in the chair, when the 201st anniversary of the birth of John Hunter was celebrated. Covers were laid for 300 persons, and among those present were the Lord Mayor of London, the Dean of St. Paul's, Sir Mathew Fell (Director-General of the Army Medical Service), Mr. J. B. Aspinall (the City Remembrancer), Dr. W. M. Willoughby (M.O.H. for the City of London), Colonel Turnbull (Chief Commissioner of City Police), Sir George Buchanan, the Presidents of the Medical Society of London, the Harveian Society, the West London Medico-Chirurgical Society, and the Chelsea Clinical Society, Dr. Howard Humphris, Sir Bruce Bruce-Porter, and Dr. Leonard Williams. Following the loyal toasts, which were drunk with muscial honours, and the toast, "The Memory of John Hunter," which was honoured in silence, the Very Rev. Dean Inge, in proposing "The Hunterian Society," eulogised the medical profession, though he had not troubled doctors much, albeit he was in his seventieth year. Regarding the professions of medicine and the church as physicians of the body and of the soul, respectively, he urged that they should cultivate friendly relations and learn from each other. Psychology made a connecting link between religion and medicine, and if the one profession could renounce its proclivity for what he might call the magical element and the other its frequent disposition towards materialism, coöperation might follow with great advantage. He closed with an eloquent testimony to the practical effects of the advance of medicine.

Dr. Westerman, in reply, after recalling Hunter's position as the great pioneer of modern surgery, gave a sketch of the Hunterian Society which, he said, was founded in February, 1819, by a number of City doctors, for the cultivation and promotion of the science and practice of medicine, and the name of Hunter was adopted as an earnest of the spirit in which the affairs of the Society should be conducted. Without a breach the meetings of the Society had been held in the City of London, and though it had had its ups and downs it was very much alive at the present time; thus in 1922 there were 152 members, while at the present moment there were 350. The Society was open to all registered medical practitioners, including women, and these took an increasing interest, if not as yet an active part in the business. Dr. Westerman then recalled to the audience the fact that there had passed away during the week Miss Helen Hunter-Baillie, the senior representative of John Hunter's family, and concluded with a warm tribute to the Lord Mayor of London and his predecessors for their hospitality, to the hon. secretaries for their work, and especially to Mr. and Mrs. Mortimer Woolfe for much hospitality.

Mr. A. E. Mortimer Woolfe, in proposing the toast of "The Lord Mayor and the Corporation of the City of London," reminded his hearers that in the cricket match between Oxford and Cambridge 37 years or so ago the present Lord Mayor of London went in first for Cambridge, while the Rev. Canon T. R. Hine-Haycock, who had said grace that evening, went in first for Oxford. The Society had a life-long tradition of relations with the City of London and its Corporation, and it owed much to Sir Kynaston Studd, especially in the matter of the reception which had been given to Prof. Zaaijer, of Leyden, who delivered a Hunterian lecture at the Mansion House last month. The Lord Mayor, in reply, said that it was interesting to know that while the Society's meetings had been held in the City, many of them in the last seven years had been held at the Mansion House. It gave him pleasure to remember that a memorable one had been held in his year of office. Some of the activities of the City of London of to-day would have appealed, he was sure, strongly to John Hunter, for not only did the Corporation look after the health of the City, but took steps, through its medical organisation, to prevent malaria and other tropical diseases from entering the country. In this connexion, he added, it gave him particular pleasure to mention the good work done by Dr. Willoughby, who was now their medical officer of health. Sir Kynaston Studd having referred to the fact that only one Lord Mayor of London had been a medical man—namely, Sir Thomas Crosby in 1911—who was also, in his time, president of the Hunterian Society, closed with

remarks upon the activities in the City in respect of technical education, scholarship, and scientific research.

Mr. Ivor Back proposed "The Guests and Kindred Societies," coupling with the toast the names of Dr. Walter Carr (President of the Medical Society of London), Sir Squire Sprigge (Editor of THE LANCET), and Dr. W. M. Willoughby, who all briefly replied.

MOORFIELDS ANNUAL DINNER.—The annual dinner of past and present students of the Royal London Ophthalmic Hospital was held at the Langham Hotel on Feb. 7th, when Mr. C. H. Usher, consulting ophthalmic surgeon to the Royal Infirmary, Aberdeen, occupied the chair and 70 students and guests were present. Among the guests of honour were Sir John Rose Bradford, Vice-Admiral Arthur Gaskell, Air Vice-Marshall David Munro, Prof. G. Elliot-Smith, and Mr. Theodore Luling. During the evening the Dean of the Hospital, Mr. C. B. Goulden, presented a report, which showed a record admission of new students—134 as against 121 in 1925. The number of students attending the practice of the hospital was 182, and during the year 406 lectures were given by members of the staff with the assistance of the lecturers in anatomy and physics. Among the examination successes last year were two diplomas of F.R.C.S. Edin. At the final examination for the D.O.M.S. of the Conjoint Board, of the 59 candidates who presented themselves, 48 were students of Moorfields and of the 36 successful candidates, 31 had pursued their studies there. Last year's new departure of inviting extra-mural lecturers to give courses had led to crowded audiences to hear Mr. Traquair lecture on "Perimetry," Prof. Elliot-Smith on "The Optic Connexions of the Brain," Prof. H. Hartridge on "The Resolving Power of the Eye," and Dr. James Kerr on "The Education of the Partially Sighted." The staff of lecturers had been strengthened by the addition of Miss Ida Mann and Mr. W. S. Duke-Elder, in the special departments of embryology and physiology. The Dean remarked that in spite of the generosity of Sir William Lister, who had built for them a small additional lecture room, further space was still needed, especially a lecture room to seat 50 students, an enlarged library, a reading room for students, and new pathological and bacteriological laboratories. He hoped that a place would be found for all of these in the building scheme upon which the hospital was shortly embarking.

CARDIFF MEDICAL STUDENTS CLUB (LONDON BRANCH).—A dinner will be held at Frascati's Restaurant on St. David's Day, March 1st. It is hoped that many of the students of this school now working in London hospitals will be present.

THE Bath Mineral Water Hospital is being enlarged by the addition of 30 beds.

WAITING LISTS AT MANCHESTER.—The Manchester local voluntary hospitals committee has just published its statistical report for the year 1927. It shows that at the close of that year nearly 5000 surgical cases were awaiting admission. The cost of in-patients averaged £7 14*s.*, towards which they contributed an average of £1 3*s.* 8*d.*

CITY OF LONDON TRUSS SOCIETY.—When the lease of this Society's premises in Finsbury-square expires three years hence it is proposed to obtain a site, in the City if possible, for a building in which hospital treatment can be given, it being impossible, for lack of space, to obtain much assistance from the general hospitals. In the meantime an official application for the use of beds is being made to St. Bartholomew's Hospital.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Dr. Hector Cameron will lecture for the Fellowship on Monday, Feb. 25th, on Appendicitis and Other Causes of Acute Abdominal Pain in Children. The lecture will be delivered at the Rooms of the Medical Society of London, Chandos-street, Cavendish-square, W., at 5 P.M., and is free to members of the medical profession. On Wednesday, Feb. 27th, at 4 P.M., at the Wellcome Museum of Medical Science, 33, Gordon-street, W.C., Dr. Gwynyett Gordon will give a clinical demonstration on the leukæmias and Hodgkin's Disease, and at the same time on the same day Dr. Kenneth Playfair will demonstrate cardiac cases at the Royal Waterloo Hospital (both demonstrations free). A week's intensive course begins at the Brompton Hospital for Chest Diseases on Feb. 25th, and at the Hospital for Sick Children, Great Ormond-street, morning course will be held from Feb. 25th to March 9th. Early application is desirable as the course is limited to 20. In March two special courses only will be held, the dates of both being March 11th–23rd. One is an all-day course at the Royal National Orthopædic Hospital (minimum entry, ten), and the other is an ophthalmological course at the Royal Eye Hospital, consisting of instruction in the afternoons. Copies of all syllabuses and information about the general course at the various hospitals affiliated to the Fellowship may be had from the Secretary, at 1, Wimpole-street, London, W. 1.

Obituary.

SIR BERTRAM WINDLE, M.D., D.SC. DUB., F.R.S.

NEWS has reached this country of the death of Sir Bertram Windle, at Toronto, on Feb. 14th, at the age of 70. The Roman Catholic Church loses in him one of its foremost British apologists, and the medical profession is deprived of a man who distinguished himself in more than one field of work.

Born in England to Irish parents, Bertram Coghill Alan Windle was the son of the Rev. S. A. Windle, and grandson, through his mother, of Admiral Sir Josiah Coghill. At the time of his birth his father was vicar of Market Rasen in Lincolnshire, but it was not long before he went back to Ireland as rector of Kingstown, and Bertram attended the local grammar school before going to Repton. At Trinity College, Dublin, which he entered as an undergraduate, he was conspicuous as an agnostic—a circumstance perhaps attributable to his father's vigorous religious views. His academic career was brilliant, and after holding minor posts in Dublin he was appointed pathologist to the General Hospital at Birmingham, where the next 20 years of his life were to be spent. Within 12 months he had joined the staff of the Medical School as professor of anatomy and anthropology, and in the years that followed he was largely responsible for the movement which resulted in the formation of the University of Birmingham. The ability which he displayed as dean of the medical faculty recommended him for the post of principal of Queen's College, Cork, when this fell vacant. Here his energetic administration bore much fruit, and under its new name of University College the institution prospered rapidly. The movement for an independent University of Munster found in Windle an able leader, and legislation to this end had been approved in principle by Dublin Castle when the success of Sinn Fein at the polls put an end to its progress. This was a severe blow to Windle, and in 1919 he resigned his appointment at Cork in favour of the chair of anthropology at St. Michael's College in the University of Toronto, which he occupied at the time of his death.

Whilst at Birmingham, Windle came under the influence of John Henry Newman, and in 1902 he joined the Roman Church. The relation of scientific facts to revealed religion interested him immensely, and this interest was reflected in numerous books and articles. The popularity of his writing extended beyond his own church, and in 1919 the Victoria Institute departed from precedent in awarding to him, although a Roman Catholic, its Gunning Prize for one of the two best books defending revelation—namely, "The Church and Science." On anthropology and anatomy he was also a considerable writer, whilst a number of books on history and the associations of the countryside testified to a many-sided personality and a capacious mind.

Sir Bertram Windle, who was knighted in 1912, sat on the General Medical Council from 1900 to 1905 as representative of Birmingham University, and from 1914 to 1920 as representative of the National University of Ireland. He acted from time to time as examiner in anatomy to the Universities of Cambridge, Aberdeen, Glasgow, and Durham, and was elected to the Royal Society as a young man. His merits were recognised by the grant of honorary degrees by the Royal University of Ireland and by Birmingham, Boston, and Marquette Universities. Pope Pius X. created him a Knight of the Order of St. Gregory the Great, and Pope Pius XI. conferred on him the degree of Doctor of Philosophy. He was twice married, and leaves a daughter.

SIR JAMES HOSKER, M.R.C.S. ENG., J.P.

BOURNEMOUTH has lost a notable public figure by the death from influenza on Feb. 13th of Sir James Hosker, in his seventy-third year. He had been closely associated with municipal activities of all kinds there for nearly 50 years.

James Atkinson Hosker was the son of James Hosker, of Liverpool. Born in 1857 he was educated privately and at the London Hospital. After qualifying M.R.C.S. in 1882 he was the first resident house surgeon at the Royal Boscombe (later Royal Victoria) and West Hants Hospital, with which his connexion was lifelong, for he was appointed to the honorary staff in 1884, and on his retirement as senior surgeon in 1903 he was elected hon. consulting surgeon. It was not merely in a professional capacity that he served the hospital; he was for long its hon. secretary, and helped largely to relieve the hospital from its financial straits. His municipal work began in 1890, when on the Incorporation of the Borough he was elected a councillor of the Boscombe ward, becoming alderman in 1894, and mayor in 1896, after which he acted as chairman of the sanitary committee. Before this he was a member of the Hants County Council. He sat for 30 years on the local bench of magistrates, and his colleagues in recording their regret at his death testified to his "directness of purpose, kindness of heart, and the certainty of justice" which he administered. He was an active politician, and all through his life closely associated with the Bournemouth Conservative Association, of which he was first hon. secretary and then chairman. A keen Freemason, he founded the London Hospital Lodge, and was a member of the Grand Lodge of England. In his spare time he was a breeder of fox-terriers, and became something of an international judge of dogs. He was a familiar figure on the Queen's Park Golf Club, of which he was captain for a time, and he was the first local president of the Yorkshire Society. His love of dogs and horses led him to resent the coming of the petrol-driven vehicle, and for long after his colleagues went about in cars he was to be seen in his familiar brougham drawn by chestnut horses.

Sir James Hosker married, in 1887, Constance Georgina, second daughter of Captain George Newcomen, R.N., who survives him without issue.

WE regret to record the death of Dr. ROBERT KINNEAR HAY GILLESPIE, at his home in Leeds, on Feb. 13th. Dr. Gillespie had a distinguished career as a student at Glasgow University, gained many awards of merit, including the John Hunter medal in surgery, and graduated as M.B. in 1915. For a short time he served as a resident medical officer on the staff of the Glasgow Royal Infirmary. Thereafter he joined the Royal Army Medical Corps, and was posted to Salonica, where he served until he was invalided home in 1918. Appointed on his return to the East Leeds War Hospital, he was subsequently transferred to the War Hospital at Beckett's Park, Leeds. He joined the staff of the Ministry of Pensions when the latter hospital came under the control of the Ministry in 1920, and remained in the pensions service until 1927. In September of that year he entered into private practice in the Headingley district of Leeds, and rapidly gained the confidence and liking of a large circle of patients. In the Army, and later in the Ministry of Pensions, Dr. Gillespie gave ungrudgingly of his abounding energy, and many disabled ex-Service men will remember him, not only as a skilful and attentive surgeon, but also as a friend and adviser. His chief hobby was engineering, and his manipulative dexterity was manifest not only in the operating theatre but also in the training workshops of the various hospitals to which he was attached. His strong and engaging personality brought him many friends, who sincerely regret his death at the early age of 37. He married in 1922, and is survived by his widow.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

THURSDAY, Feb. 28th.—4.30 P.M. A meeting for discussion will take place on the subject: Ultra-microscopic Viruses Infecting Animals and Plants. The discussion will be opened by Sir Charles Martin, F.R.S.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Feb. 25th.—8 P.M., ODONTOLOGY. Mr. W. Kelsey Fry: Fractures of the Mandible in, and Posterior to, the Molar Region. Casual Communications: Mr. W. Rushton: The Use of Cement Linings in Cavities. Dr. J. Kingston Barton: The Prevention of Diseases of the Teeth in Children. Mr. F. N. Doubleday: Fractured Roots of Central Incisors with Live Pulps.

TUESDAY.—5 P.M., MEDICINE. Prof. K. Hansen (Heidelberg): The Psychical and Allergic Factors in Asthma. A short discussion will follow.

THURSDAY.—5 P.M., UROLOGY. Pathological Evening.

FRIDAY, March 1st.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.). Subject for Discussion: The Acute Ear. Short papers by Mr. Herbert Tilley, Dr. Dan McKenzie, Mr. F. F. Muecke, and Mr. C. A. S. Ridout. Mr. J. S. Fraser and Mr. E. D. D. Davis: Microtia and Atresia of the External Meatus. Demonstration: Mr. A. Lowndes Yates: Methods of Taking Records of Instability. Cases will be shown by Sir James Dundas-Grant, Dr. Dan McKenzie, and others. 5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Cases and Specimens will be shown by Mr. H. Bell Tawse, Mr. Jefferson Faulder, Mr. Lionel Colledge, Dr. Dan McKenzie, Mr. Wm. Mollison, and Mr. A. J. Wright. 8.30 P.M., ANÆSTHETICS. Paper: Dr. Gerald M. Slot: Deaths under Anæsthetics with Special Reference to their Pathology.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Feb. 25th.—8.30 P.M., Discussion on Acute Intestinal Obstruction, to be introduced by Prof. A. H. Burgess, followed by Mr. C. H. S. Frankau.

WEDNESDAY.—9 P.M., Dr. H. W. Barber: Dermatology in Relation to Other Branches of Medicine. (Second Lettsomian Lecture.)

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

WEDNESDAY, Feb. 27th.—4 P.M., Clinical Cases. 5 P.M., Dr. Tylecote: Paper on Calcium. The Meeting will be followed by a Dinner to be held at Kettner's at 6.45 for 7 P.M.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY, Feb. 25th.—8 P.M., Sir Thomas M. Legge: Thirty Years' Experience of Industrial Maladies. (Second Shaw Lecture.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, Feb. 26th.—5 P.M., Dr. J. Graham Forbes: Past and Present Diphtheria in England and Wales with special reference to the London Metropolis. (First Milroy Lecture.)

THURSDAY.—5 P.M., Dr. J. Graham Forbes. (Second Milroy Lecture.)

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Feb. 25th.—5 P.M., Mr. P. Eggleton: The Chemistry of Muscle Contraction.

TUESDAY.—5.30 P.M., Dr. Percy Stocks: Recent Work on the Genesis of Epidemics.

WEDNESDAY, THURSDAY, and FRIDAY, March 1st.—5 P.M., Dr. J. H. Burn: The Properties of, and Methods of Estimating, some Therapeutic Agents.

FRIDAY, March 1st.—5.30 P.M., Dr. J. Howard-Jones: The Hygiene of the Mercantile Marine. (Second lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 25th, to SATURDAY, March 2nd.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., Feb. 25th, at 5 P.M., Lecture by Dr. Hector Cameron: Appendicitis and Other Causes of Acute Abdominal Pain in Children.—WELLCOME MUSEUM OF MEDICAL SCIENCE, 33, Gordon-street, W.C. Wed., at 4 P.M., Demonstration by Dr. Knyvett Gordon, The Leukæmias and Hodgkin's Disease.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Wed., 4 P.M., Clinical Demonstration by Dr. Kenneth Playfair. (Heart Cases.)—The above are free.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Special post-graduate course in Dermatology. Every afternoon, clinical instruction: lectures twice weekly. Proportionate fees. Pathological demonstrations can be arranged.—BROMPTON HOSPITAL (For Chest Diseases), S.W. Intensive Course, one week.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Morning course, two weeks. Further particulars from the Secretary of the Fellowship of Medicine.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Feb. 26th.—3.15 P.M., Dr. Rubens Wade: Anæsthesia.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Feb. 26th.—5 P.M., Dr. G. B. Dowling: Seborrhœa. Seborrhœic Dermatitis.

THURSDAY.—5 P.M., Dr. W. K. Sibley; Electrotherapeutics.

ORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Feb. 25th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.
FRIDAY, March 1st.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

ATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Feb. 25th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Adie: Progressive Muscular Atrophies.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Neurosyphilis.
THURSDAY, 2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Common Lesions of Peripheral Nerves.
FRIDAY, March 1st.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Sir Percy Sargent: Cerebellar Tumours.

OSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Feb. 28th.—4 P.M., Dr. Tyrrell Gray: Undescended Testes.

ATIONAL COUNCIL FOR MENTAL HYGIENE, 78, Chandos House, Palmer-street, S.W.
WEDNESDAY, Feb. 27th.—5 P.M. (at the Medical Society of London, Chandos-street, W.), Dr. W. A. Potts: The Irrisistible Impulse.

NCOATS HOSPITAL, POST-GRADUATE LECTURES, Mill-street, Manchester.
THURSDAY, Feb. 28th.—4.15 P.M., Dr. Kletz: Diseases of the Gall-bladder.

ANCHESTER ROYAL INFIRMARY.
TUESDAY, Feb. 26th.—4.15 P.M., Mr. G. Jefferson: Treatment of Neuralgia.
FRIDAY, March 1st.—4.15 P.M., Mr. P. R. Wrigley: Demonstration of Surgical Cases.

NIVERSITY OF LIVERPOOL.
THURSDAY, Feb. 28th.—4 P.M. (in the Surgery Theatre of the Medical School), Mr. H. A. T. Fairbank: Congenital Dislocation of the Hip, with Special Reference to the Anatomy. (The Lady Jones Lecture.)

NIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, March 1st.—3.30 P.M. (at the Royal Hospital), Dr. Skinner: Neurological Cases.

Appointments.

ONES, MARY, M.B., Ch.B. Edin., has been appointed Assistant Medical Officer at the Union Hospital, Fulwood.
ICK, H. E., M.B., B.S. Lond., F.R.C.S. Eng., an additional Referee under the Workmen's Compensation Act for Ophthalmic Cases in Circuit 31, Aberayron, &c.
USSELL, BEDFORD, F.R.C.S. Eng., Assistant Surgeon to the Throat Department, St. Bartholomew's Hospital, and Honorary Surgeon to the Golden-square Throat, Nose and Ear Hospital.
AYLOR, W., M.D., Ch.B. Aberd., D.P.H., Medical Officer of Health for Shropshire.
rtifying Surgeons under the Factory and Workshop Acts: MACLACHLAN, C. F., M.B., Ch.B. Edin. (Lockerbie, Dumfries); ELLISON, H. H. L., L.R.C.P. Lond., M.R.C.S. (Syston, Leicester).

Vacancies.

For further information refer to the advertisement columns.

r County Hospital.—Sen. H.S. At rate of £100. Also Jun. H.S. £80.
rrow-in-Furness, North Lonsdale Hospital.—H.S. £130.
rmingham, Queen's Hospital.—Anæsthetist. H.P.'s., H.S's. and Cas. H.S. Each at rate of £70.
ighton, Royal Sussex County Hospital.—Cas. H.S. £120.
stol General Hospital.—H.P.'s. H.S.'s. Res. Obstetric Officer. Also Cas. H.S. Each at rate of £80.
stol Royal Infirmary.—H.P.'s, H.S.'s., Dental H.S., &c. Each at rate of £80.
ydon General Hospital.—Cas. H.S. £125.
rby, Derbyshire Education Committee.—Asst. School, M.O. £600.
chester, Dorset Mental Hospital.—Sen. Asst. M.O. £400.
rham County Council Education Department.—Asst. Oculist. £600.
t African Medical Service.—M.O.'s and Health O.'s. £600 and £660 respectively.
t Ham Memorial Hospital, Shrewsbury-road, E.—Hon. Asst. P.
ex, Administrative County of.—Asst. County M.O.H. £600.
ucester, Gloucestershire Royal Infirmary.—2nd H.S. At rate of £100.
rogate Infirmary.—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.
tford County Hospital.—Res. Surg. O. At rate of £250.
Islington Dispensary, 303, Upper-street, N.—Sen. Res. M.O. £300.
Jerusalem, St. John Ophthalmic Hospital.—Sub-Warden.
Kensington, Fulham and Chelsea General Hospital.—Hon. Phys. for Diseases of Skin.
Leeds, St. James' Hospital.—H.P. and S. £200.
Liverpool County Borough.—Jun. Asst. School M.O. £600.
Leicester, Royal Infirmary.—H.S., Res. Cas. O. Also H.P. Each £125.
Liverpool, Mill-road Infirmary, Everton.—Res. Asst. M.O. £200.
London Temperance Hospital, Hampstead-road, N.W.—Hon. Anæsthetist.
Manchester, Ancoats Hospital.—Res. Surg. O. Also H.S. At rate of £100.
Manchester Ear Hospital.—Non. Res. H.S. Also H.S. At rate of £150 and £120 respectively.
Manchester, Royal Children's Hospital.—Two Asst. M.O.'s. Each at rate of £150. Also Res. M.O. and Res. Surg. O. Each at rate of £125.
Maudsley Hospital, Denmark Hill, S.E.—Asst. M.O. £300.
Metropolitan Asylums Board, Mental Hospital Service.—Sen. Asst. M.O. £650.
Metropolitan Ear, Nose and Throat Hospital, Fitzroy-square, W.—H.S. £150.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. M.O., Cas. O., and H.P. At rate of £250, £150, and £125 respectively.
Northampton General Hospital.—Two H.S.'s. Also Asst. H.S. Each at rate of £150.
Paddington Green Children's Hospital, W.—Hon Physician. Also H.P. and H.S. Each at rate of £150.
Perth, James Murray's Royal Asylum.—Asst. Physician. £300.
Queen's Hospital for Children, Hackney-road, E.—Res. M.O. £200.
Reading, Royal Berkshire Hospital.—Hon. M.O. for Electro-Therapeutic Departments.
Rotherham Hospital.—H.P. £180.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—H.S. Also H.S. for Country Branch at Stanmore, Middlesex. Each at rate of £150.
St. Mary's Hospital for Women and Children, Plaistow, E.—Clinical Asst.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—H.S. At rate of £175.
Stepney Parish Guardians' Hospitals.—Consultant Surgeon. £350. Consultant Physician and Consultant Ophth. Surgeon. Each £200. Also Consultant Surgeon for Ear, Nose and Throat. £150.
Sudan Medical Service.—M.O. £E.852.
Surrey, Administrative County of.—County M.O.H. £1800.
Surrey, County Council.—Asst. M.O. £600.
Swansea, Adelina Patti Hospital, Craig-y-Nos.—Asst. Res. M.O. £250.
Swansea Hospital.—H.S. Also H.P. Each £150.
Throat, Nose, and Ear Hospital, Golden-square, W.—H.S. £100.
Torquay, Torbay Hospital.—H.S. £175.
Wallasey, Victoria Central Hospital.—Jun. H. S. At rate of £100.
West London Hospital, Hammersmith-road, W.—Hon. Asst. Anæsthetists.
Western Ophthalmic Hospital, Marylebone, W.—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.
Westminster Hospital.—Medical Registrar.
Willesden General Hospital, Harlesden-road, N.W.—Clin. Asst.

Births, Marriages, and Deaths.

BIRTHS.

DE JERSEY.—On Feb. 11th, at Audley House, Swanage, the wife of Dr. G. W. S. de Jersey of a daughter.
DENNEHY.—On Feb. 12th, at a nursing home, Northgate, Bury St. Edmunds, the wife of Dr. J. J. Dennehy, of a son.
MACKINTOSH.—On Feb. 14th, at Kenilworth, Stoneygate-road, Leicester, the wife of Dr. J. M. Mackintosh, of a daughter.
WATERSTON.—On Feb. 13th, at Langroyd, Colne, the wife of Dr. G. Fyfe, Waterston, Deloraine, Windermere, of a son.

MARRIAGES.

GORDON—ROBERTSON.—On Feb. 11th, at St. Paul's, Knightsbridge, Hugh Walker Gordon M.C., M.R.C.P to Jean Helen. eldest daughter of Mr. and Mrs. H. W. Robertson, of Fintry, Brook, Godalming, Surrey.

DEATHS.

BEYTS.—On Feb. 12th, at Queen Alexandra's Military Hospital, Millbank, London, Colonel William George Beyts, C.B.E., R.A.M.C. (retired), Medical Officer of the Tower of London.
GILLESPIE.—On Feb. 13th, at Beech House, Otley-road, Leeds, Dr. Robert Kinnear Hay Gillespie, M.B., Ch.B. Glasg., aged 37.
HUME.—On Feb. 12th, at Vron, Bangor, N. Wales, Douglas Walter Hume, M.B., B.S. Lond., F.R.C.S. Eng., aged 47.
RUTTLEDGE.—On Feb. 16th, at Alpha-villas, South Farnborough, Colonel William Frederick Ruttledge, late R.A.M.C., aged 91.
WINDLE.—On Feb. 14th, at Toronto, Canada, from pneumonia, Sir Bertram Windle, F.R.S., LL.D., M.D., aged 70.
WOODD WALKER.—On Feb. 9th, in London, Basil Woodd Walker, M.D., of 6, Dawson-place, W., aged 73.

POCKETT.—In ever loving memory of Lieut.-Col. L. W. Pockett, M.D., M.R.C.S., L.R.C.P., L.S.A., who entered into rest Feb. 18th, 1928. From his wife and daughter.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PANEL SYSTEM IN BIG TOWNS.

To the Editor of THE LANCET.

SIR,—I am a practitioner in a good street in the south-western district of London. Two maids have been with us for many months and, assuming that they were on the panel, I have systematically paid the whole 1*s.* 2*d.* per week myself. A fortnight ago one of these women was seized with an acute attack of influenza. She was put to bed, and I offered to send for her panel doctor. She said that she had none, and never had had. Accordingly I rang up an acquaintance who runs a panel, and asked him to see the maid and take her on his panel. It was a Sunday morning, and he refused to come. I tried six other panel doctors, not one of whom would come. At last I prescribed for her myself, and sent the prescription to the nearest chemist to be made up for a panel patient. The chemist refused to dispense the medicine. He said that panel dispensing did not pay him, and I had better send to a chemist, a considerable distance off, who did a large amount of panel work. This chemist I found did not open at all on Sundays. Eventually I had to pay for the medicine myself at the first chemist's establishment. These bare facts seem to me to indicate need for improvement in matters of panel practice. I am informed that for numbers of servants, who are on the panel, their employers not only pay the insurance but, when illness comes, call in their own medical men. So far as my own observation goes it appears that in country districts the panel system works well and honestly. In towns, it seems, the panel doctor may reap the fees while other doctors do the work on their patients. I enclose my card.

I am, Sir, yours faithfully,

AGGRIEVED.

*** The provision of facilities for dispensing medicine to insured patients has always been rendered difficult by early closing and the fact that many chemists have lock-up premises, but in most areas of South London there is a rota of chemists who undertake in turn to be on duty late at night and on Sundays. This is certainly an arrangement which should prevail elsewhere. It seems, however, that the chemist who was approached and was actually available was not at liberty to dispense for an insured person except on presentation of the official form used by doctors on the panel. For the rest, "Aggrieved's" grievance is real enough, for he was certainly the victim of careless improvident maids who, although entitled to medical benefit, had obtained no medical cards, or who had not troubled to get their cards signed by a practitioner on the panel. We have repeatedly emphasised the point, and we do so again, that it is largely the ignorance of the insured population in regard to their rights and duties under the medical benefit provisions of the Insurance Acts that hinders these Acts from fully developing their beneficent purpose. It should be construed by every insurance committee as part of its duty to make known the provisions of the Acts in an effective way to every class of insured person. Domestic servants badly need this information.—ED. L.

BRUCELLA ABORTUS IN MAN.

As recently as Dec. 29th (THE LANCET, 1928, ii., 1335, 1338) we published reports of the occurrence of *Brucella abortus* in human beings, and two further case-reports appear in our columns this week. We therefore take the opportunity of informing interested readers that the December issue of the *Giornale di Clinica Medica*, which has just reached us from Parma, is wholly devoted to undulant fever. Besides original papers it contains a bibliography of some 30 pages.

ETHER AND DUTY-FREE SPIRIT.

IT has been pointed out to us that in an annotation published in THE LANCET of Feb. 9th, 1929, p. 295, an incorrect impression may have been gained from the words in which the provision is described of pure ethylic ether at the price hitherto charged for that derived from methylated spirit. The circumstances are as follows. As far back as 1923 the Association of British Chemical Manufacturers made representations to the Commissioners of Customs and Excise concerning the disadvantages arising in the manufacture of ether from the use of methylated spirit. As a sequel to discussion of these circumstances, The British Drug Houses, Ltd. themselves approached the Customs and Excise for permission to employ special denaturing agents other than methyl alcohol when the preparation of anæsthetic ether was in question. The privilege was granted in 1926 that such special denaturing agents could be employed, and it was made openly

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(*Continued from p. 374.*)

THE following official bulletin has been issued signed by Sir Stanley Hewett and Lord Dawson o Penn :—

FRIDAY, FEB. 15TH.

In spite of the inclement weather His Majesty th King continues to make slow progress, and since hi departure from London has increased in weight.

(*Continued from previous column.*)

available to all manufacturers of ether, but The British Dru Houses, Ltd. appears to have been the only firm that too advantage of it. At any rate, from that date all ethe manufactured by that firm has been prepared from duty-fre alcohol without the use of methylated spirit, so that th committee set up by the Medical Research Council and th Royal Society of Medicine have acted in accordance with special permission already granted, although only take advantage of by one firm ; and we have here not so much a innovation as a sequel.

COLD SHOPS AND SICKNESS CLAIMS.

IN a recent letter to the press Mr. J. R. Leslie, J.P general secretary of the National Amalgamated Union Shop Assistants, Warehousemen, and Clerks, points ou that under the provisions of the Factory Acts, workroom and factories have to maintain "a reasonable temperature, but unfortunately there is no legal provision in this respe for shops. The Union has an approved society under th National Health Insurance scheme with a membership 35,000, among whom the normal sickness claims per wee range from 800 to 1000. Last week these claims ran up t 1749. In the trade-union department the normal sickne claims among a provident membership of 25,000 averag 500 per week. Last week the claims reached 925. The bul of the sickness certificates are for influenza, some f "severe cold," and a number for bronchitis. Each winte whenever there is a spell of very cold weather, the clain increase largely. There is no doubt, Mr. Leslie think that the conditions under which many members of th Union work—shops with open doors, without fires or heatin of any description, cold marble slabs, everything they hand cold—have a bad effect on their health. Many of the girl he adds, suffer severely from chilblains.

AN ELECTRICALLY HEATED CUSHION.

WE have received from Thermega, Limited (manufacture of Electrical Appliances, 53, Victoria-street, London, S.W.1 a sample of an electrical heating pad for local applicatio The pad is a smaller variety of the Thermega blanket whic has been on the market for some time and is well establishe in practice, especially at sanatoria and places where childre are nursed under open-air conditions. The heating cushio or pads are supplied in two sizes, the larger one bein 16 inches by 12, the smaller two inches less in each dime sion. They can be used on any current between 100 an 250 volts without adjustment, warming up quickly wh the current is turned on, and not overheating owing to device known as the Birka tempe ature regulator whic automatically switches off the current when the desire temperature is reached. The small size gives in use a co stant heat of 120° F. ; the larger model can be regulate at will to give 90°, 120° or 150° F. The cost in current is le than one-quarter of a penny an hour, even if the unit char is 6*d.* The pads are intended for the local application heat and the relief of pain in such conditions as rheumatis sciatica, and pleurisy, and we can testify to the relief afford in the case of an aching joint. The price of the cushion 21*s.* for the small, 33*s.* for the larger size, extras being indiarubber cover for use with a wet compress and a great length of flexible conductor.

Andrew Lang's Birthplace as a Nursing Home.—Vie field, Selkirk, the birthplace and early home of Andre Lang, has been bought by the Selkirk Cottage Hospit Association for a nursing home.

Ski-ing Accidents.—In Dr. Knoll's article, which appear in our last issue, torsion fractures of the metacarpal bon should have been described as very frequent in *subalpi regions* (not Central Switzerland). Line 15 in the paragra on the Common Injuries should read : The fall therefo is its consequence, not its cause.

An Address

ENTITLED

DEVIATIONS FROM THE STANDARD.

Delivered before the Interstate Post-Graduate Medical Association of North America

BY O. LEYTON, M.D. CAMB., D.SC., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL.

ENGLISH workers recognise that the United States has made enormous advances in the study of medicine, and the authorities of the larger hospitals realise their responsibility in bringing these advances to the aid of the suffering poor in the wards of their institutions. To facilitate this they favour sending qualified men and hospital nurses, when opportunity offers, over to the States to carry out research work and study the methods there elaborated. When these visitors return they often bring with them heaves of tables based upon the average or standard. These tables are of great value in the hands of the experienced, but those who have little opportunity of using them tend to exaggerate their value and raise them to an importance second only to those tablets which Moses brought down from Mount Sinai.

INDIVIDUAL PECULIARITIES.

I should like to draw attention to a deviation from the standard which in the past has led me and others astray and made us diagnose disease when none has been present. Sometimes, not always, it is easy to arrive at the average or standard, but extremely difficult to define what deviation from that standard is an individual peculiarity and to distinguish that from an illness. At first sight it seems to me that the more accurate the apparatus we possess the greater the difficulty. For instance, before we possessed clinical thermometers there must have been little difficulty in deciding whether a patient was feverish or not. The flushed face, the hot skin, the rapid pulse, and perhaps delirium, led the experienced physician to a definite conclusion. A short time ago I asked some of my colleagues at what temperature they thought pyrexia began; one replied, at 99·6° F., and another at 101° F. If the accepted definition of "truth" be "that which satisfies," then neither of my colleagues was speaking the truth. It would not be wise to say that a man was feverish because his temperature was 100·4° F. after exercise; as you know, the temperature of most of us will rise to that height if we run a mile. Nor would it be wise to say that a man with a temperature of 99·6° F. is not feverish in certain circumstances. These difficulties in definition give us food for reflection, but are comparatively simple when compared with individual peculiarities; most of us have met healthy people whose normal temperatures have been 97·6° F. or below. These are not arguments against the use of accurate instruments, but illustrate that, although it may be quite easy to define the normal average or standard, it is extremely difficult to decide what deviation from the standard is important.

Let me take one other illustration with which you are all well acquainted—the blood pressure. Perhaps it would be more accurate for me to say the pressure in a bag 4 in. wide which, when applied to the upper arm, will obliterate the pulse at the elbow. Most of the instruments in use to-day do not measure the systolic pressure, a fact which can be shown quite rapidly and clearly by applying a plethysmograph to the forearm; it will be found that the volume of the arm increases whilst the bag is supposed to be just obliterating the artery. What is the "standard blood pressure"? Some assert that when it is measured in millimeters of mercury it is the age in years added to 100. It is now more than 30 years ago that I first took a blood pressure measuring apparatus into a ward of a hospital, and during that time I have seen more and more importance attached to its readings. To-day many patients come to the physician stating that they are suffering from "blood pressure." When I am faced with this diagnosis I inquire whether the patient has any symptoms, or whether the diagnosis is based entirely upon the fact that the blood pressure apparatus records a pressure higher than the average. In the latter case many tests must be carried out before the diagnosis of disease is pronounced. I can call to mind a very wonderful old lady, the widow of England's most famous biologist, who for the latter ten years of her life had a systolic blood pressure measured by the Riva Rocci apparatus of over 280 mm. of mercury. The only symptom that developed was a minute hæmorrhage into one eye, and at the age of 87 she died from a condition which, as far as we know, has no relation to blood pressure. No doubt many of you have seen cases somewhat similar, and also the reverse; blood pressures of 125 mm. in patients of 70 years and more who have been hale and hearty and shown no evidence of myocardial disease. I suggest that there should be different standard blood pressures in different States, for it is difficult to believe that the same average pressure occurs in Alaska as in Georgia. An average blood pressure in a country that reaches almost from the Equator to the Pole seems to me to be of little more value than an average skin-colour for the inhabitants of the State of Georgia.

LOW RENAL THRESHOLD FOR SUGAR.

Many years ago the diagnosis of diabetes mellitus followed the reduction of Fehling's solution by the urine; later it was recognised that many substances besides dextrose reduced Fehling's solution, such as pentose, lævulose, lactose, glycuronic acid, and several others. It is doubtful whether many errors in diagnosis were made in these early days, because the urine at that time was only examined for sugar when thirst, polyuria, &c., suggested disease. Later the diagnosis of diabetes mellitus was reserved for true glycosuria, and then Saloman showed that individuals might pass dextrose in the urine without the sugar in the blood rising above the normal average. He called this condition "renal glycosuria," because his first few cases had albuminuria in addition. It is now recognised that the peculiarity is not of the kidney, and the name was replaced first by that of diabetes innocens, which is a bad name because there is no diabetes—in other words, no thirst and no polyuria. Many call the condition orthoglycæmic glycosuria, whilst I suggested the name of "negligible glycosuria," because it is not of importance. A very pronounced case of this peculiarity came my way several years ago. After the administration of 50 g. of dextrose by the mouth the sugar in the urine rose to over 10 per cent., although the sugar in the blood did not exceed 0·16 per cent. (Fig. 1). These numbers seemed so unusual that I thought it wise to have them confirmed at two laboratories by different observers. Not only is the renal threshold different for different individuals, but it varies from time to time in the same individual. Some time after a meal it tends to fall. A boy of 14 was given 50 g. of dextrose by the mouth after a meal containing considerable quantities of carbohydrate (Fig. 2). The concentration of the sugar in the urine rises whilst that in the blood falls, even if we take into consideration the residual urine of the pelvis of the kidneys and ureters.

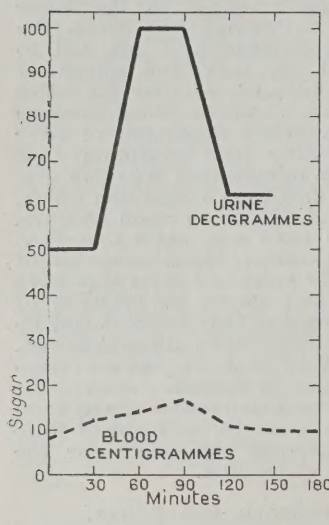
Many others have made similar observations, amongst them the distinguished expert on diabetes mellitus, Dr. J. E. Paullin of this city.

In my experience this peculiarity of a low renal threshold for sugar does not protect from diabetes mellitus. I have seen one case of a man with a low renal threshold develop diabetes mellitus, and amongst my cases of diabetes mellitus nearly 0·5 per cent. have a low renal threshold. Since Dr. E. P. Joslin has never seen diabetes mellitus develop

in an individual with a low renal threshold, there must be some difference in the people on the two sides of the Atlantic.

One case made a great impression upon me—a military man who was getting on in years and who developed thirst, lost weight, and had glycosuria and hyperglycæmia. When placed upon a diet and given insulin the concentration of sugar in his blood was kept between 0·08 per cent. and 0·16 per cent. throughout the 24 hours, but in spite of that he passed quite a lot of sugar in his urine. One day he said to me: "I believe you are giving me monkey gland, not insulin, because there is still sugar in my urine; but, undoubtedly, I am feeling very much better, and now, when I walk down Bond-street, I am interested in seeing what is under the hats." This patient had to be taught how to estimate the sugar in his blood in order that he might take an intelligent interest in his complaint.

FIG. 1.

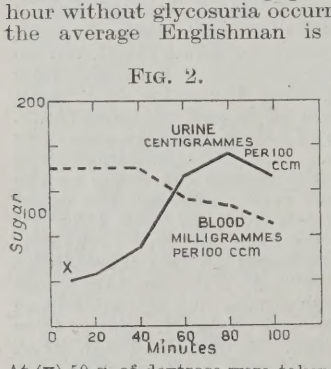


This peculiarity of low renal threshold for sugar seems to be inherited and may perhaps have some relation to diabetes mellitus. Many of the cases in which I have found a low renal threshold for sugar are children of parents with the same peculiarity, whilst four have diabetic parents. I have seen two sisters, daughters of a diabetic mother, one with true diabetes mellitus and the other with a low renal threshold for sugar. This family failing has been worked out very fully by Dr. Urban Hjärne.[1]

THE STANDARD RATE OF BURNING AND/OR STORING CARBOHYDRATE.

Many years ago R. T. Woodyatt, W. D. Sansum, and R. M. Wilder showed that after a fast of 24 hours a healthy man might have dextrose poured into his veins at the rate of 0·8 g. per kg. of body-weight per hour without glycosuria occurring. In my experience the average Englishman is not so competent a kataboliser of sugar. Although my experience of the intravenous method of introduction of sugar has convinced me that it is the more accurate, because it eliminates the error due to different rates of absorption through the intestinal tract, nevertheless I have been forced to make most of my observations after oral administrations, because many of my patients have never entered hospital. I have devised the following method for determining the rate at which sugar is burnt and/or stored.

FIG. 2.

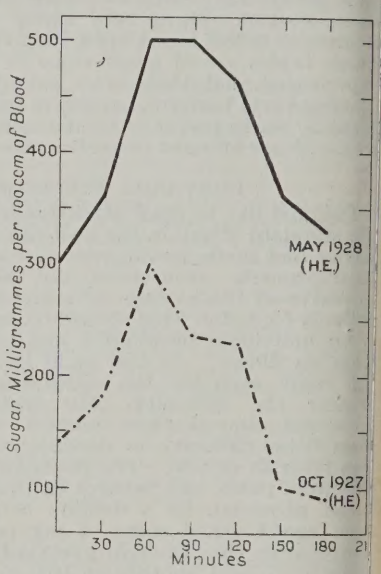


At (x) 50 g. of dextrose were taken by mouth after a meal containing carbohydrate.

After a fast of 12 hours the patient's blood is taken and the sugar in it estimated. Then he receives a definite dose of grape-sugar, dissolved in water and flavoured with lemon-juice. The dose depends upon the concentration of sugar in the blood after the 12 hours' fast; if it be low, 60 g. of sugar are given; if it be high, as little as 20 g. may be considered the best dose. If too big a dose be given, the test would be prolonged over too many hours. At intervals of half an hour or less samples of blood are collected and the bladder is emptied; all the urine is kept. The test in continued for at least three hours.

By estimating the sugar in the samples of blood, one is able to determine how long it has taken for the sugar in the blood to fall to 0·12 per cent., or to what it was before the sugar was administered. Having found this time, the urine passed during that period is mixed, measured, and the sugar and urea in it estimated. The quantity of sugar is subtracted from the dose given, whilst the amount of sugar which may have been liberated from the protein which has been broken down is added. This latter figure is arrived at by multiplying the urea excreted by 1·7. Some may criticise me adversely for adding this quantity, saying that it is far from certain that in the metabolism of a healthy man the carbohydrate part of the protein molecule is at any time converted into dextrose. I admit this, but meet the criticism by drawing attention to the fact that when the efficiency of carbohydrate metabolism is good, then the addition of this liberated sugar makes but little difference in the result, while, when the carbohydrate metabolism is poor, then there is no doubt that the greater part of the carbohydrate liberated is actually turned into dextrose.

FIG. 3.



Observations upon a number of healthy individuals and individuals with low renal threshold show that about 60 g. of dextrose can be stored and/or burnt per hour when administered by mouth. This method measures fairly accurately and is therefore comparable with the thermometer and sphygmomanometer. It allows one to note the progress of a patient by repeating the test at intervals, and for this reason, in my opinion, it is of very great diagnostic importance.

An untreated case of diabetes mellitus may go downhill rapidly.

Fig. 3 shows the curves from a patient who had a mild glycosuria and a low renal threshold for sugar which was discovered when he attempted to insure his life shortly after an operation. I decided that the depression of his carbohydrate metabolism might be due to a recent anæsthetic, anxiety, and poor general health, and advised him to take a holiday and return for further examination in four weeks' time. He did not take a holiday nor did he present himself until six months had passed, and during that time the disease had made great progress. The carbohydrate metabolism efficiency had fallen from 55 per cent. to 24 per cent.

The question arises as to what fall in carbohydrate metabolism constitutes disease. Whenever a tissue alters slowly the time at which disease begins is not a fixed hour; different observers would give different times. Hyperthyroidism may progress quite far in a phlegmatic individual before it appears to become a disease, whilst a very slight increase in the activity of the thyroid gland in a "live wire" would show itself definitely and immediately. Many years ago the diagnosis of diabetes mellitus was comparatively easy because the disease was not recognised until thirst, glycosuria, and wasting were present; now the diagnosis is far from simple. Perhaps the time has come when the name of the disease should be changed, because the diagnosis

[1] See THE LANCET, 1928, i., 1077.

of the complaint may be made before there is thirst or polyuria and before there is persistent glycosuria. Hypoglycopyresis, although cacophonous, conveys the meaning that the power of burning sugar is depressed; when that depression is due to pancreatic disease the term subinsulism seems appropriate. At the present day the diagnosis of diabetes mellitus should be reserved for patients who either present symptoms or are unable to katabolise more than 25 per cent. of the normal average of sugar or are gradually losing the power of katabolising carbohydrate.

Illustrative Cases.

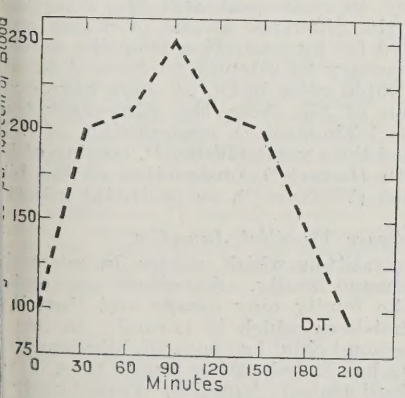
To show that these limitations are necessary I refer to cases which in the past would have been diagnosed as diabetes mellitus, but which, in my opinion, are simply cases of a congenital carbohydrate metabolism considerably below the average.

A woman of 31, had nursed her brother for diabetes mellitus; she examined her urine and found that it reduced Fehling's solution. She went upon a diet and, later, was sent to me for investigation. I found that her renal threshold was low, in the region of 0·16 per cent., but in addition to that the sugar in her blood rose to 0·20 per cent. after a lunch consisting of meat, vegetables, and ice-cream. After breakfast, including marmalade, the sugar in her blood did not rise above 0·12 per cent. The explanation of this, I think, may be pancreatic fatigue. When she was submitted to a carbohydrate metabolism efficiency test the sugar in her blood rose to 0·25 per cent. and took quite a long time to fall. She proved to have a carbohydrate efficiency of 33 per cent. (Fig. 4). This is considerably worse than that of the case of diabetes mellitus referred to above (Fig. 5).

Her brother was submitted to similar tests, and his carbohydrate metabolism efficiency was found to be a little lower than that of his sister. These two patients had not had symptoms of diabetes mellitus, but the male had had intermittent glycosuria for some years. After due consideration of the circumstances, which were quite exceptional, I came to the conclusion that I was justified in advising these two patients to eat and drink whatever they liked for a year and then be submitted to similar tests again. This was done, and their efficiency was found to be somewhat better rather than worse.

There are so many possible explanations for this improvement that it would be but a waste of time to discuss them here. I came to the conclusion that these patients were not suffering from diabetes mellitus, although their power of burning and/or storing sugar was much less than the average. If anyone prefers to take the view that the two patients were cases of mild non-progressive diabetes mellitus, which obviously needs no treatment, I shall be the last person to contradict him because his definition of illness will be different from mine, and it is useless for two people to argue when they do not attach the same meaning to one another's words.

FIG. 4.



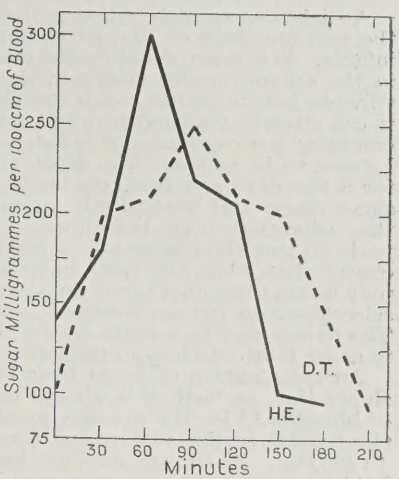
Having decided that these two cases were not cases of illness, I looked through my notes of cases and came to the conclusion that the condition is not so very rare, and that quite a number of patients are upon restricted diets when they might with impunity eat and drink whatever they liked. By no means, however, do I advocate departure from the rule: "treat every patient who passes dextrose in his urine as a case of diabetes mellitus until there is satisfactory evidence that the patient is not suffering from that disease."

CONCLUSION.

The following deviations from the standard, therefore, are not, as far as we know, illnesses, and yet have appeared to be: (1) pentosuria, lævulosuria, lactosuria, &c.; (2) low renal threshold for sugar; (3) temporary short hyperglycæmia following a meal; (4) low carbohydrate metabolism, probably congenital.

In the majority of diabetic patients metabolism permits a greater amount of fat in the food than carbohydrate. This is so common that many physicians have no time to study the exceptions; those that have time find that nearly 2 per cent. can utilise more carbohydrate than fat.

FIG. 5.



The study of so-called inborn errors in metabolism makes us realise that there are very many and varied deviations from the standard which can be recognised with comparative ease and are not diseases. I cannot help thinking that, although the metabolisms of all men bear a great similarity to one another, they differ in detail; I doubt whether our faces differ more than our metabolisms. One of the most convincing pieces of evidence that the metabolisms of different people are different exists in the fact that bloodhounds are able to track different people. If all the metabolisms of all men were identical the volatile substances elaborated would be identical, and dogs would be unable to distinguish people by their scent.

GRAVE FAMILIAL JAUNDICE OF THE NEWLY-BORN.

BY A. C. HAMPSON, *M.C.*, M.A. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO QUEEN MARY'S HOSPITAL, STRATFORD; MEDICAL REGISTRAR, AND HILDA AND RONALD POULTON RESEARCH FELLOW AT GUY'S HOSPITAL.

UNDER this title, in 1920, an account was given by Sir Humphry Rolleston [1] of a condition occurring in successive infants of a family and usually proceeding to a fatal termination. The condition is rare, but during the last four years 18 cases, occurring in 17 families, have been under my care. Eight of these have been seen during the last nine months, and it appears probable, from the observations of colleagues, that the condition is more common than is generally recognised, advice not being sought because it is thought that nothing can be done. From the returns of the Registrar-General for England and Wales it appears that during the last seven years about 1800 infants have died of jaundice during the first four weeks of life, without obvious cause such as sepsis or obliteration of the bile-ducts.* I have

* It is probable that this figure errs in being too low, because deaths from such conditions as umbilical sepsis have been deducted from the figures for jaundiced infants, although only a proportion of these develop jaundice. In calculating the figure, an allowance has been made for cases of congenital obliteration of the bile-ducts, based on the known preponderance of males suffering from this condition. The figure given includes cases due to congenital syphilis but not certified as such; these

(*Continued at foot of next page.*)

recently seen three cases where treatment was commenced so late that the outlook appeared hopeless; of these two survived, but one died very shortly after treatment was commenced. My object in writing this paper is to draw attention to a form of treatment which has been successful in cases where it has been started sufficiently early. The condition shows considerable similarity to the physiological jaundice of the newly-born, and this is briefly reviewed for purposes of comparison.

Physiological Jaundice.

A slight degree of jaundice is often obvious within the first few days of life, particularly in premature infants. It is first noticed on the face and chest, then in the sclerotics, and finally in the hands and feet. Obvious jaundice is not seen before the second day, but it can often be rendered apparent earlier by carefully emptying the capillaries of blood, when the skin will be seen to be yellow. The depth of colour increases for a few days and then gradually fades, though in some cases, and particularly in premature infants, the coloration may last much longer. The first parts to lose the colour are usually the extremities, except that when the nails have been stained they may retain the colour for a considerable time, and the sclerotics also remain coloured for a longer period. The babies may be a little drowsy, but the condition is never fatal and has no pathological significance.

An examination of blood from the umbilical vein shows that at birth this always contains an excess of bilirubin.[2 3 4] The average quantity is 1 : 75,000, the normal in the adult being from 1 : 1,000,000 to 1 : 400,000. A similar amount has been found in babies born per vias naturales, and in those delivered by Cæsarean section. The condition is not, therefore, postnatal in origin, though the excessive production is continued during early postnatal life. Bilirubin can first be detected in measurable quantities in the blood at the fifth month of fœtal life and it increases in amount up to full term, the amount present in premature infants at birth being less, on an average, than in those born at full time. Attention has already been drawn to the fact that frank jaundice is much more likely to be present after birth in premature infants, and in them the postnatal rise of bilirubin in the blood is accentuated. After birth, in normal infants, the quantity of bilirubin in the blood rises, reaching a maximum on the third or fourth day, the amount in some cases being sufficient to cause definite staining of the skin. Thereafter, the bilirubin-content of the blood gradually falls, reaching the normal in about four weeks. In interpreting these results, stress must be laid on the presence of bilirubin in the blood before birth. It is not, therefore, in any way due to intranatal or postnatal changes of temperature, circulation, or nutrition. The amount of bilirubin in the blood of babies delivered by Cæsarean section or per vias naturales is approximately the same. It is fair to infer, therefore, that the degree of jaundice is not influenced by the actual parturition.

The sharp rise in the bilirubin-content of the blood after birth must be due to some factor associated with extra-uterine life, because it occurs both in premature and in full-time infants. That it is not due to feeding is shown by the fact that it begins before the infant is put to the breast, and the rise is approximately the same in infants fed on the breast and in those fed artificially. Two possible explanations suggest themselves, the first being that before birth only a fraction of the fœtal bilirubin is excreted by the liver, the remainder finding its way through the placenta into the maternal blood stream. After birth the liver may be some time in assuming its full function, and bilirubin would accumulate in the infant's blood. A similar delay in assumption of full function is found in other organs. The second possible explanation for the postnatal rise lies in the assumption of some maternal influence —hormonic, for example—restraining hæmolysis. After birth there is a fall in the hæmoglobin percentage, bearing an approximate relationship to the increase of bilirubin. Attempts have been made to explain the fall in hæmoglobin as being due to dilution. In rabbits the fall is accompanied by an increase in the amount of iron deposited in the liver, and there can be little doubt that in these animals active destruction of red cells is taking place. This is quite understandable; the percentage of hæmoglobin before birth is high, possibly in association with the active metabolism of the fœtus and the low percentage saturation of the fœtal blood with oxygen. Further, infants in which the jaundice is deepest usually show the greatest fall in hæmoglobin. Van den Bergh's test on the serum gives a positive indirect reaction only. These findings suggest that the jaundice is hæmolytic. Recently, the work of Murphy and Minot [5] has directed considerable attention to the liver as the source of an anti-hæmolytic agent, and it may well be that a hormone of this nature passes from the mother to the fœtus in utero, the sudden increase in hæmolysis after birth being due to the withdrawal of the maternal source of this substance. The passage of hormones across the placenta is one familiar enough in the case of other endocrine secretions as, for example, that of the thyroid. The blood of the infant, moreover, possesses certain points in common with that in pernicious anæmia, in which an extract from the liver is of undoubted value in overcoming the hæmolysis; this point will be more fully discussed in a later paper. Whether the delay in assumption be one of excretion, or in the production of an internal secretion, it seems probable that it is one in which the liver is largely concerned.

In view of the similarity of the processes occurring in prenatal and in early postnatal life, it appears probable that the difference is one of degree only, and is accounted for by separation from the mother. It seems unnecessary to attempt to account for the rise in the bilirubin after birth, as some have done, by reabsorption of bile from the alimentary tract (Knopfelmacher,[6] Thomson [7]), compression of bile-ducts by dilated liver veins (Weber [8]), cooling of the skin after birth (Lauret [9]), obstruction of the bile-ducts by mucus (Virchow [10]), or postnatal infection (Epstein [11]).

Grave Familial Jaundice.

This is a condition which occurs in successive infants of the same family. Sometimes one or two members of the family may escape and then it is usually the first-born which is normal. In one or two cases the second child has been slightly jaundiced and the colour has lasted rather longer than is the case with physiological jaundice. Occasionally a normal child may be found in a family in which both older and younger children have died of the disease. I have seen one case of twins, occurring in such a family, in which one twin was normal and the other jaundiced.

This condition has many points in common with physiological jaundice. The jaundice, however, usually shows itself on the first day, often within a few hours of birth; indeed, the infants may be born jaundiced. Thereafter it rapidly deepens until the skin becomes a deep bronze. Occasionally, however, the jaundice does not appear until the second day and the depth of colour attained, though considerable, may not be so intense. These cases may occur in

---

(*Continued from previous page.*)

cases cannot be estimated from the returns. It also includes cases which may not be familial, but cases which I have seen in which jaundice has occurred within the first 24 hours after birth, and in which the jaundice was not due to the well-recognised causes, have without exception responded equally well to the treatment recommended in grave familial jaundice, though admittedly, when other members of the family have not died of the complaint, it is always possible that the infants might have recovered without treatment. The uniformly good results obtained, however, appear to justify the use of the statistics quoted above.

I should like to acknowledge the courtesy and great assistance extended to me by Dr. A. J. Thompson, of the Registrar-General's Office.

families in which the other infants have shown the typical degree of coloration, and do not appear to offer a better prognosis than the others. The infants are usually drowsy, take the breast poorly, and lose weight. The liver and spleen, as a rule, are not enlarged at birth, and often do not become enlarged during the course of the disease. In others, moderate enlargement of the liver and spleen may occur, particularly of the former. The enlargement, however, does not appear to be so great and the liver is not as hard as in cases of obstruction of the bile-duct. The stools are normal in colour, but the bowels tend to be costive. In all the cases I have seen the urine has been dark and has contained urobilin —and usually bilirubin—in excess of the amounts frequently found in the newly-born. Hæmorrhages do not form a conspicuous feature of the disease, though they may occur near its end, particularly in the subcutaneous tissues over the forehead, where they are not to be confused with the small spider-nævi which are common in all jaundiced babies and which rapidly disappear with the subsidence of the jaundice. In one case seen recently on the seventeenth day there was obvious melæna shortly before death.

The main features during the course of the disease are an increasing jaundice, increase in drowsiness, and loss of weight. Death usually occurs within three weeks, commonly within 14 days, and frequently with convulsions. In other cases, the end is extremely sudden. In some cases there have been attacks in which the infant has assumed a peculiar shade of greyness mixed with the icteric tint. In these attacks respiration becomes very shallow and slow and the heart-beat may be barely perceptible. They are presumably due to medullary failure and strychnine has been successful in my cases. In all the cases in the present series the parents have been in good health, the Wassermann reaction has been negative, and the pregnancies have been uneventful. In a number of cases the metabolism of the mother has been carefully studied before and during the pregnancies and no abnormality has been detected.

The condition is illustrated by the following case:—

The mother was married in 1908 at the age of 20. The first two children died in the first few weeks of life in convulsions. They were said to have been jaundiced, but the history is vague. The next child was born after six and a half months' gestation and was jaundiced; it only survived for three hours. The next child was jaundiced soon after birth, but recovered; this child is living. The next pregnancy resulted in a miscarriage at four months. Of the remaining seven pregnancies, all had come to full term; three had resulted in stillbirths, the children being born jaundiced. The remaining four were not obviously jaundiced when born, but jaundice developed a few hours after birth and rapidly deepened. The infants were very drowsy and died within periods ranging from three to eight days. The Wassermann reaction of parents and children was negative. On one occasion the van den Bergh reaction on the mother's blood immediately before labour was reported to be slightly positive, but this is usual in normal pregnancy; the mother was certainly not obviously jaundiced, and probably the finding has no significance as far as the present condition is concerned. At post-mortem no obvious cause for the jaundice could be ascertained.

Ætiology.

The disease closely resembles the physiological jaundice of the newly-born. A further delay in the assumption of hepatic efficiency would result in a greater degree of jaundice in the infant. Recent work on animals suggests that the products of the destruction of red cells may be extremely toxic. Intraperitoneal injections of small amounts of hæmolysed red cells in adult rabbits appear to produce little obvious effect; the injection of a proportionate amount in young, growing animals invariably inhibits growth. In the pregnant animal it leads to the death of the fœtuses in utero, usually with abortion; in two cases, in which the pregnancy was early, the fœtuses were retained in utero, with the formation of a mole. This finding will be more fully discussed in another paper; it is only mentioned here to show that the products of red cell destruction are toxic, particularly in young animals. The hæmolytic nature of the disease is supported by the fact that the infants become progressively anæmic. The accumulation of the toxic products of hæmolysis, inadequately excreted by the liver, would sufficiently account for the symptoms.

Diagnosis.

In the 18 cases discussed in this paper the parents have been apparently healthy and there has been no abnormality during the pregnancy. There are other cases, which I have not included under this disease, in which there is evidence of maternal toxæmia. In three published cases, those of Nason,[12] Tylecote,[13] and Rolleston,[14] the mothers had recurrent jaundice during the pregnancies, and during the last year I have encountered a case with a similar history. This patient also had albuminuria with œdema during her pregnancies, and on several occasions had fits. When I saw her she was not pregnant and the urine showed no abnormality. In two other cases (Smith,[15] and Ritchie[16]) the mother was jaundiced during one of the pregnancies. Jaundice in the infants is only a symptom, and it appears probable that there are many causes. Cases in which there is definite maternal toxæmia appear to belong to a different group from those which concern this paper, and deserve a separate name to differentiate them from other familial jaundices of the newly-born, which also have a grave prognosis. Even in these other cases, however, it appears to be quite as justifiable to regard the maternal toxæmia as fœtal in origin, as to regard the fœtal condition as due to the toxæmia of the mother.

Familial acholuric jaundice may give rise to mild jaundice in the early days of life but, as Chauffard[17] says, "the patients are more icteric than sick." I have notes of three families, however, in which all the children died during the first few weeks of life after a progressively increasing jaundice. An examination of the fragility of the red cells to hypotonic salines shows a markedly diminished resistance, and one of the parents is almost certain to exhibit a similar phenomenon. In each of the three cases mentioned, the red cells of the mother showed an increased fragility. In this condition the red cells are also smaller in diameter than the normal.

Congenital Obliteration of the Bile-ducts.—This condition, often occurring in several members of the same family, is usually associated with complete obliteration of the bile-duct, though the degree is variable. The liver shows evidence of biliary cirrhosis, supposed by Thomson[18] to be secondary to the biliary stasis. Rolleston[1] considers that the cirrhosis is due to maternal toxæmia, "followed by a descending obliterative cholangitis," while Wyard[19] thinks that the cholangitis is ascending from the duodenum, due to irritation set up by swallowed liquor amnii. In one of McGibbon's[20] cases of grave familial jaundice there was obstruction, though not obliteration, of the biliary papilla. In two of my own cases of grave familial jaundice there was in each family a history of one case being diagnosed post mortem as obliteration of the bile-ducts, but I have been unable to obtain further particulars. The two conditions are easily confused and the observation may be without significance. In grave familial jaundice both sexes appear to be equally affected; in obliteration of the bile-ducts, according to Thomson,[18] boys are affected more often than girls. Jaundice usually manifests itself about the second day and is progressive. On the other hand, it may not appear until the second or third week. The stools are white or only slightly pigmented and the urine is dark, owing to the presence of bile. Hæmorrhages often occur subcutaneously or from the mucous membranes. The child may appear quite fit until late in the disease. On the other hand, I have seen one case, verified at post-mortem, in which death occurred on the fourth day. In this condition the liver is usually considerably

enlarged and hard. The main points of distinction from grave familial jaundice are the colour of the stools and the size and hardness of the liver.

Congenital syphilis may rarely produce a pericholangitis with enlargement of the liver and spleen. Jaundice occurs early and is progressive, and the infants are usually extremely cachectic. The stools are pale and the urine is dark. Hæmorrhages occur, and though the liver is enlarged it is not usually so hard as in congenital obliteration of the bile-ducts. Other evidence of syphilis may be found in the infants or in the parents.

Infective jaundice is associated with other infective processes, either at the umbilicus or in the intestines. At the onset of jaundice the infant is usually obviously ill and the temperature is raised. It is wakeful and irritable and refuses its food. There is often cyanosis. The condition is, of course, not familial, though in cases of jaundice occurring for the first time in a family it is a condition which should be considered. The diagnosis is usually obvious.

Prognosis.

Of 130 cases collected by Rolleston, 100, or 77 per cent., proved fatal. In the families of my own cases, out of 90 untreated infants, 75, or 83 per cent., were fatal. In the combined series, 80 per cent. were fatal. With treatment, the prognosis appears to be good. Of 18 cases occurring in 17 families, 17 have recovered, and the eighteenth was seen so late in the course of the disease that it appears to be without significance, except to emphasise that treatment should be started early. Of the 17 which have recovered the eldest is now nearly four years of age, and all appear to be healthy children. This agrees with the impression of other writers on the subject, that when recovery occurs it is nearly always complete, though Morris [21] gives an account of a girl who lived for four and a half years, being jaundiced for practically the whole time.

Treatment.

If the suggestions given as to the ætiology of the disease be correct, treatment should be directed to the prevention of hæmolysis. In discussing physiological jaundice it was suggested that some substance was present in the mother's blood which was lacking in that of the infant, and in a former paper [4] on this subject an account was given of in vitro experiments on the effect of serum in inhibiting hæmolysis. These experiments confirmed the suggestion that the infant was short of an anti-hæmolytic agent, which could be given by injecting the mother's serum. It appeared, if grave familial jaundice differed only in degree from physiological jaundice, that if hæmolysis could be retarded for a time, the prognosis ought to be that of physiological jaundice, and therefore good.

The effects of treatment by serum are, perhaps, best illustrated by continuing the history of the case recorded above:—

The thirteenth pregnancy of this patient was uneventful. A male infant was born at full term. Jaundice developed within a few hours of birth. On the second day the infant was becoming very drowsy and very deeply jaundiced; the urine was dark and contained bile. On the third day the mother remarked that the child "was going just like the others." In view of the almost certain fatal termination and of the experimental findings referred to above, it appeared reasonable to give the child injections of serum, in the hope of supplying a missing factor. On the evening of the third day, 10 c.cm. of the mother's serum were injected intramuscularly. A similar dose was given on each of the two following days. Even after the second dose the child appeared to have improved. By the ninth day the bilirubin content of the blood had fallen to the level normally found in a child of this age. On the tenth day the jaundice was obviously fading; the child had a lusty cry, was not so drowsy, was feeding well, and had stopped losing weight. Following the advice given by Rolleston, artificial feeding had been used. Breast-feeding was now commenced, and from this time onwards improvement continued. The child is now nearly four years of age and recovery appears to have been complete.

The patient has recently had a fourteenth pregnancy; the infant again became fairly deeply jaundiced, but treatment was commenced earlier and the colour disappeared more rapidly.

In subsequent cases the infants have, as far as possible, been fed on the breast throughout.

In gauging the amount of serum required, the best guide appears to be the amount of bilirubin in the blood of the child. Serum has been given intramuscularly into the buttock, in daily doses of 5–15 c.cm., according to the condition of the child. The injections have been continued until the bilirubin content of the plasma has fallen to approximately 1:150,000. The amount required has varied from 30 to 60 c.cm. The serum is very rapidly absorbed, and no ill-effects have been observed. Serum, and not whole blood, should be used for two reasons: (1) red cells are not rapidly absorbed and the injections would give rise to hæmatomata, with their attendant risks of sepsis, which would almost certainly be fatal; and (2) absorption of hæmolytic products would almost certainly aggravate the condition.

Summary.

In the condition described as grave familial jaundice, the yellow colour usually appears on the first day; the temperature is normal; the stools are normal in colour; the urine contains excess of urobilin and frequently bilirubin; the liver and spleen are not usually enlarged. In untreated cases the condition is progressive and the prognosis is bad; on the other hand, in 17 out of 18 cases treated with serum the infants have recovered; in the eighteenth case treatment was only commenced on the seventeenth day, a few hours before death, when the child already appeared moribund. The case cannot be regarded as one in which the treatment has failed, but serves to emphasise the gravity of the condition and the necessity for early treatment.

In conclusion, I should like to stress two points: (1) Jaundice occurring within the first 24 hours after birth should always be regarded as serious. (2) In cases in which there is a familial history of infants dying of jaundice, even if the jaundice does not appear until the second day, it should be regarded with equal gravity.

ENLARGEMENT OF CUMBERLAND INFIRMARY.—A new out-patients' department of this Carlisle hospital, which has cost over £33,000, has recently been opened. It forms the first part of a series of extensions which include two new wards, enlargement of the nurses' home, the reorganisation of the administration block, and the provision of a pathological department.

AN INVESTIGATION INTO THE CAUSE OF ARTHRITIC MUSCULAR ATROPHY.

By A. E. BERYL HARDING, B.M. Oxf., M.R.C.P. Lond.

(*From the Surgical Unit Laboratories, University College Hospital, London.*)

In a previous communication[1] an account was given of some experiments which had been undertaken with a view to investigating the muscle-wasting that accompanies arthritis. A review was given of the bibliography[2] and the various theories that have been advanced. Experiments were planned which should throw some light on the metabolic activity of the muscles, and it was found that there were marked differences in this respect between muscles which had wasted as a sequel to arthritis and those in which the atrophy resulted from disuse. In the former there is a great increase in the oxygen consumption, the average oxygen used by atrophied muscle being as much as 8·3 c.mm. per 1·0 g. muscle for one minute, as against 4·6 c.mm. for the normal. In the muscles which were wasted from disuse (immobilised in plaster-of-Paris) the oxygen use was only 5·1 c.mm. per g. per minute. It was suggested that the increase is the result of an increased katabolism, the atrophy resulting from failure of the reparative powers to keep pace with this undue tissue breakdown. In pure disuse atrophy the almost unaltered oxygen consumption probably means that there is no increased katabolism, but simply an impairment of the synthetic powers on the affected side. The suggestion was put forward that arthritic wasting might be due to an increased number of impulses (or abnormal impulses) arising in the joint, making the spinal centres abnormally excitable—i.e., that there is a reflex basis for the wasting. In pure disuse, on the other hand, where is a reduction of afferent stimuli, for when a joint is immobilised proprioceptive impulses, which depend on movement for their initiation, will be in abeyance. The wasting under these circumstances results from partial suppression of reflex excitation; the spinal centre has in no way been interfered with, and re-establishment of activity finds it able to resume its functions in the regular way.

Method of Experiment.

To put the question to the test, it was decided to cut the posterior nerve roots carrying the afferent nerves from the knee extensors of the left hind-leg and to allow of complete degeneration before setting up an arthritis. The right side was left intact to serve as a control. The animals used were rabbits and cats. Great difficulties were experienced in setting up an arthritis in both series, and the methods employed in the case of rabbits have been fully described in a previous paper.[2] Wasting was constant in every case of arthritis, but the degree varied considerably, and was not related to the duration of the arthritis. The cats were given a preliminary injection of isopral and sedonal, 1·15 c.cm. per kg. as recommended by Lambert,[3] and subsequently anæsthetised with open ether. Laminectomy was done, and the lower three lumbar and upper two sacral posterior nerve roots were cut on the left side. All the animals were very ataxic for the first 10–14 days, then gradually learnt to control their deafferented limbs. After one month injections were made into both knee-joints. The following organisms, obtained from the Lister Institute, were used for this purpose: *Streptococcus frequens*, *S. salivarius*, and *Diplococcus rheumaticus*, also a strain of the scarlet fever streptococcus, obtained from the Wellcome Research Laboratories. No constancy of reaction was found. Sometimes arthritis followed the injection, sometimes there was no result. Repeated injections of the same organism, as used by Kniest Faber,[4] and of different organisms were then tried, but with similar periodic success.

An attempt was therefore made to set up a preliminary irritation by injecting cantharidine 1/200 in acetic ether, iodoform, or eucalyptus 1/14 in iodoform, and giving subsequent injections of organisms. Again arthritis sometimes followed, but in other animals there was no reaction. The following series consists only of the animals which showed clinical enlargements of their joints. There was no structural fixation of the joints, and all the animals used their arthritic limbs freely, and appeared to suffer very little pain.

Results.

Three sets of controls were made: (*a*) section of posterior roots only, to show that no atrophy results from deafferentation; (*b*) arthritis set up in left joint only, to show ratio of wasting to body-weight; (*c*) bilateral arthritis set up, with no preliminary nerve section, showing that an approximately equal wasting can be produced. The animals were kept alive 8–10 weeks, and their weight was taken at the beginning and end of the experiment.

TABLE I.—*Controls.*

R.Q. = Right quadriceps. L.Q. = Left quadriceps.

Table I. (A) shows that in cats the average weight of the quadriceps extensor femoris is between 1·22 and 1·38 per cent. of the total body-weight. In (B) the degree of wasting is such that this percentage is reduced to 1·09–0·83 per cent., and this is again shown in (C) where even lower figures were obtained —0·76 and 0·84 per cent. The wasting on each side was very similar.

TABLE II.—*Experiments.*

Section of left roots, organisms, or chemicals into both joints—showing reduction of wasting on deafferented side.

I 7	2400→2044	23·1	21·7	1·13	1·06

Nine experiments were then made on laminectomised animals, and it is clear that the result of deafferenting a limb is to prevent the wasting almost entirely. (Table II.)

The right quadriceps, the nerve-supply of which was intact, showed the usual degree of wasting. The left quadriceps in four of the experiments was 1·3 per cent. of the body-weight—i.e., within normal limits—in two 1·14 and 1·18 per cent. The two low values may be due to the fact that the animals were in very poor condition and had had severe degrees of arthritis. Experiments J 4 and I 7 do not fit in with the series at all, and no adequate explanation of them has been found. In both a bilateral arthritis was established of approximately equal intensity, but despite the fact that the left legs were deafferented the wasting was more marked in the left quadriceps than in the right. The animals were in good condition and the arthritis of average degree.

These results show that the wasting is due to some reflex cause, but before investigating this point further it seemed advisable to find out whether a similar basis could be demonstrated in disuse atrophy. Laminectomy was again done on cats, and after 4–6 weeks, when the skin was soundly healed and the animals fairly steady on their legs, the left leg was immobilised in plaster-of-Paris. The leg was completely flexed at the hip, the knee being extended and the bandage, after several turns round the leg below the knee, was then taken round the body, the whole leg being then included in the subsequent bandaging. The leg was thus carried parallel with the body as if in a sling. The animals soon learnt to walk on three legs and, as the foot and leg were well padded with cotton-wool, no swelling took place. After immobilisation for 6–8 weeks the animals were killed and the knee extensors dissected and weighed. The following figures show clearly that no reduction of the wasting is effected by deafferentation.

5	→2600	35·0	25·4	1·34	0·97

Clearly, then, no reflex cause can be invoked in explanation of disuse atrophy. This was not altogether unexpected, in view of the metabolic differences already referred to.

Discussion.

It is suggested that the sequence of events is as follows. The presence of the arthritis provides an abnormal stimulus to the afferent nerve endings, as a result of which the corresponding spinal centre becomes unduly excitable. This causes an abnormal discharge of impulses to the muscles, and results in a condition of heightened activity, which is evidenced by the raised oxygen consumption. This state of affairs might last long after the original cause had subsided, and would account for those cases quoted by Charcot,[5] in which muscular wasting was present for as long as one year after the initial injury.

Lippmann and Selig,[6] working on rabbits, found that the atrophy following arthritis closely resembles that following nerve section and tenotomy. They point out that "the muscle atrophies that follow tenotomy and nerve section are due to cessation of muscle function; are therefore true disuse atrophies. The atrophy that follows experimental arthritis is preceded by muscle relaxation—muscle collapse—and the subsequent course is the same as that which obtains following tenotomy and nerve section. It is therefore reasonable to conclude that arthritic atrophy is also a disuse atrophy. The muscle disuse, however, is not caused by voluntary immobilisation or external fixation but is due to muscle collapse. Hence the theoretical and experimental evidence leads to the inference that although arthrogenic atrophy must be considered a disuse atrophy, it is not due to immobilisation, but is caused by a reflex mechanism." That there is some reflex mechanism underlying the atrophy is proved by my experiments, but the suggestion that this is reflex muscle collapse is not tenable in view of the fact that the knee-jerk was present and active in all my animals with an intact reflex arc, and the arthritic limbs were as freely used as the sound. Furthermore, these same observers found practically no atrophy as the result of immobilisation. They conclude that "the atrophy obtained by others with experimental immobilisation was caused not by the fixation itself; it was no doubt due to extraneous factors, injury, excoriation," &c. I would like to emphasise that in no single animal of mine which had been in plaster-of-Paris was there any injury, excoriation, swelling, or other evidence of impaired blood-supply. It is therefore hard to understand or to accept the above findings.

I think my experiments raise more questions than they answer, but one thing is clear: two forms of muscular atrophy have been differentiated, one reflex and one due to disuse, and for the latter there is no reflex basis. The nature of the reflex mechanism underlying the former is still unsolved.

I have to express my sincerest appreciation to Prof. C. C. Choyce for his unfailing interest and assistance in the work, which has been done under his direction. I have also received constant help from H. E. Roberts, who has given me many suggestions as to the making up of the solutions employed, and other technical points.

THE VERNES METHOD OF ESTIMATION OF FLOCCULATION IN SYPHILITIC SERA.

BY H. WANSEY BAYLY, *M.C.*, M.R.C.S. ENG.
SOMETIME PATHOLOGIST TO THE LONDON LOCK HOSPITALS
DIRECTOR, VENEREAL DEPARTMENT, ST. GEORGE'S HOSPITAL.

NEARLY twenty years ago I published a note in THE LANCET on the then new "serum diagnosis of syphilis,"[1] and in the two subsequent years further notes[2 3] on the value of the Wassermann reaction for the control of treatment. In a small volume published in 1912, I emphasised the non-specificity of the reaction, and pointed out that the value of the test, though great, was relative and not absolute, and that positive reactions occurred apart from syphilis.[4] Six years later[5] I uttered a warning that the value of the Wassermann reaction, both for diagnosis and control of treatment, was limited, and that what was necessary to ensure uniformity of result was a standardisation of reagents so that the variants and the personal factor were reduced to a minimum.

The Vernes test eliminates variants and reduces the personal factor, and therefore (always providing that the Vernes photometer is an instrument capable of accurate measurement of small differences in opti density) must theoretically be acknowledged as a possible advance on the Wassermann test. The further evidence in regard to the Wassermann reaction that has accumulated during the last ten years has not altered my opinion. During this decade I have occasionally recorded further instances of contradictory Wassermann reactions at short intervals of time and without intervening treatment, and positiv

Wassermanns in cases where no confirmatory evidence, either historical or clinical, could be obtained.[6]

During the last 20 years I have reiterated my opinion that while the Wassermann reaction was a good servant it was a bad master, that the test was clearly not specific, that there appeared no logical reasons why other similar chronic infections should not produce a like reaction, and that, therefore, no one should be dogmatically branded as a syphilitic on the evidence of a positive Wassermann reaction unsupported by any other historical, clinical, or pathological evidence.

Records at St. John's Hospital.

By the courtesy of Dr. E. Ofenheim I have recently been given the opportunity of comparing the results of tests applied to the sera of syphilitics by Wassermann's method and by the syphilometric method of Vernes which Dr. Ofenheim has carried out in his laboratories at St. John's Hospital, Lewisham, for the last three years.

I examined 863 reports. The Wassermann reports were: negative, 464; positive, 368; doubtful, 31. Of these 863 tests, 635 (74 per cent.) showed complete agreement between the two methods; that is, the positive Wassermanns showed Vernes figures of "7" or over, the negative Wassermanns showed Vernes figures below "3," and the doubtful Wassermanns showed Vernes figures between "3" and "7." The remaining 26 per cent. of cases were composed as follows:—

W.R.	negative	and	Vernes	doubtful	9 per cent.
„	positive	„	„	negative	7 „
„	„	„	„	doubtful	5 „
„	negative	„	„	positive	2 „
„	doubtful	„	„	negative	2 „
„	„	„	„	positive	1 „

Most of the "Wassermann positive, Vernes negative" results were cases which had received treatment and in which there was no clinical evidence of infection when these tests were taken, and the charts seemed to show that the Vernes test registers reaction to treatment much more delicately than the Wassermann, but that a Vernes negative during treatment can only be taken as showing that the treatment is producing a definite effect, and is no indication whatever that cure has been effected. If, however, treatment has not been received recently the Vernes negative appears to be of greater diagnostic value than the Wassermann negative. If the "under treatment Vernes negative Wassermann positive" cases and the "doubtful" in both tests are eliminated, the cases of definite divergence in diagnosis by these tests are reduced to 4 per cent. in one-half of which the Wassermann is positive and Vernes negative, and in the other half the Wassermann is negative and the Vernes positive. In these cases clinical evidence seems to support both tests about equally.

Simplicity and Uniformity of the Vernes Technique.

When once the optical apparatus has been accurately adjusted—a matter requiring patience and experience—the reading of the illuminated scale of optic density of the various sera on Vernes photometer is so simple that the personal element is almost eliminated; much to my surprise, my very first readings coincided almost exactly with those obtained in Dr. Ofenheim's experienced hands. It is essential to maintain the room and water-bath temperatures constant at the prescribed degree, and to mix and measure the reagents efficiently and accurately, so that a comparatively small and undisturbed room is necessary, and the test can only be satisfactorily carried out in a well-equipped laboratory.

The Wassermann "home-made" reagents must necessarily vary with the different laboratories, and from time to time in the same laboratory, as a really accurate titration of these reagents is often impossible and generally impracticable. In the Vernes test all the variant Wassermann reagents (locally prepared alcoholic heart extract, complement, and hæmolytic system) are dispensed with, the only reagents used consisting of Vernes's centrally prepared horse heart extract, absolute alcohol, and doubly distilled water. In the Vernes method, therefore, there is absolute uniformity of reagents, whether the test is carried out at the Vernes prophylactic institute, Paris, or in other laboratories in France,[7 9], England,[12 13] America,[8] Italy,[11] Argentine,[14] Denmark,[10 15] Switzerland, or Germany, where a large number of tests have now been recorded. Not only are the reagents constant, but the temperature, the rate of mixing reagents, and the mechano-optical method of recording the degree of optic density are constant. The result is read on a scale which permits little personal error. The amount of flocculation or optic density is not estimated by the human vision, nor is it recorded in agreement with a self-appointed scale by the human brain. The difference between the methods of arriving at a degree of flocculative optic density with the Vernes photometer and with naked-eye estimation is somewhat analogous to naval range-finding with a modern instrument, as compared with the old-time human judgment based on vision. Neither the Wassermann nor the Vernes test can be claimed as pathognomonic, as in both tests a heart extract is used which is not a true syphilitic antigen. In the Vernes test, however, this alcoholic extract of horses' heart is constant, as it is accurately prepared in bulk in Vernes's laboratories, and distributed in small phials to all laboratories undertaking the Vernes test.

All the laboratories that have investigated Vernes's method appeared to agree that the Wassermann reaction and the Vernes test accord in the great majority of cases. The point which has not yet been finally and definitely established is which of these tests is the more reliable where they differ. The large amount of evidence that is accumulating seems, however, to suggest that the Vernes test may ultimately prove the more reliable, and that the occasions when the Vernes tests contradict themselves, or are at variance with clinical history, may be less frequent than with the Wassermann reaction. The final verdict on the comparative value of the Wassermann and the Vernes tests lies in the future, and will only be arrived at after an immense number of reactions to both tests have been recorded in the laboratories of the world. There seems little doubt, however, that the Vernes test merits serious consideration, and it seems a matter for regret that St. John's Hospital, Lewisham is, as far as I know, the only laboratory in England (with the quite recent exception of St. Mary's Hospital, Paddington) where this test is being investigated.

It is claimed that the Vernes method is not only applicable for serum but is also of value with the cerebro-spinal fluid, on which it can be used in two ways, for the estimation either of what we may call the Wassermann substance or of the albumin content.

In this note I do not propose to discuss either the theory or the technique of the Vernes test, which are recorded elsewhere,[7 8 12] but I wish, as a student of the serum reaction of syphilis for 20 years who has always tried to maintain a strictly unbiased view, to draw attention to the data in regard to the Vernes test, and to stimulate further research on it in Great Britain. The clinician alone can decide which of the tests has the greater value, either for diagnosis or the control of treatment, and he can only decide after prolonged and comparative experience of both tests in relation to the clinical progress of the case. So far, the clinician has been afforded little opportunity in this country of forming his own opinion. The charts I have examined at St. John's Hospital, Lewisham, and those published in the literature, seem to suggest that those cases which exhibit contradictory or doubtful Wassermanns show less contradiction or doubt with the Vernes test. The published records of the Vernes test also seem to show that different individuals react very differently to arsenobenzol, mercury, and bismuth, and that a fall in the Vernes optic density figure may occur more readily in one patient with arsenobenzol, in

another with mercury, and in a third with bismuth; also that the downward curve of the Vernes optic density chart may often be hastened by a change of treatment. They appear also to confirm clinical opinion that arsenobenzol is perhaps the least potent drug for the treatment of central nervous syphilis. Curiously enough, some of the Vernes test results suggest that the mercury pill, the stand-by of our fathers, is of quite considerable value in some cases and hardly deserves the contempt that has recently been its lot. Vernes's test also seems to indicate that there is at least temporary involvement of the cerebro-spinal fluid during the secondary period of infection, and that a normal Vernes optic density figure of the blood serum may be present with a high optic density figure of the cerebro-spinal fluid. I have not been able to find any record of clinical or pathological relapse in syphilitic cases where the Vernes optic density figure of both blood and cerebro-spinal fluid has returned to and remained at normal for eight months. If, as Vernes claims, there is reasonable hope that, after such a short period of normality, it is safe to declare a person definitely cured, a very great achievement would be recorded, and one that would relieve both clinician and patient from much anxiety. The Vernes optic density figure also seems to fall and rise more closely and definitely in relation to clinical improvement and relapse than does the Wassermann reaction.

In the Wassermann reaction the quantitative estimation from the strongest positive to the complete negative is necessarily limited as, even when three strengths of serum are used (2½ per cent., 5 per cent., and 10 per cent.) the scale is a short one, since complete inhibition of hæmolysis, partial inhibition, and complete hæmolysis are the only degrees that can be recorded with each dilution. With the Vernes test, on the other hand, the scale runs from zero up to or beyond 280 degrees, although over "7" is taken as a definite positive, so that the degrees of positiveness or of Vernes's optic density figure above "7" cover a very long scale in which small alterations in "positiveness" are clearly and definitely shown. The doubtful zone is a very narrow one in the Vernes test, lying only between "3" and "7," as less than three degrees of Vernes's optic density figure is definitely normal. Sera that show Vernes's degrees between "3" and "7" must be returned as doubtful, and should be re-examined on several occasions. Over five degrees is probably positive. It must be understood that the Vernes degrees are relative, not absolute, and are arrived at by subtracting the optic density scale reading of the incubated serum-alcohol-distilled-water mixture from that of the serum-horse-extract-distilled-water reading. For instance, if the reading in one were 134, and the other 136, the difference or Vernes's figure would be "2," and the serum not syphilitic; while if the reading of the one were 172, and the other 197, the difference would be "25," and the serum syphilitic; and if the reading of one were 183, and the other 187, the difference would be "4," and the serum reported as doubtful.

Even if the Vernes test is no more accurate than the Wassermann for diagnostic purposes, its far greater range of degrees of positiveness offers a marked advantage as a method of controlling treatment and estimating the therapeutic value of the drug to the individual. It is not uncommon to record a Vernes degree of positiveness of well over "100" in untreated cases of syphilis, and this degree may fluctuate between such a high figure and "7" according to the treatment and the individual's reaction to the treatment. The Vernes chart may record these great variations in positiveness, while the Wassermann reaction remains unchanged at "strongly positive ++."

If there is a greater fall in the Vernes degree after a bismuth than after an arsenobenzol course (or vice versa) it is highly probable that the drug producing the greater fall is the more potent for that patient at that time.

The opsonic index has departed to the limbo of discredited tests because different indices were so frequently obtained with the same serum by different observers. It is not unknown for one laboratory's doubtful Wassermann to be the negative of another, and perhaps even the positive of a third, while the encouraging factor about the Vernes test is that the Vernes optic density figure of the same serum, as reported by different observers, usually lies within an extremely narrow zone. Whatever the ultimate verdict may be, Dr. Ofenheim and St. John's Hospital, Lewisham, can be congratulated on their pioneer work in this country in investigating the Vernes test.

Conclusions.

The widespread opinion of responsible observers with an extensive experience of the Vernes test appears to agree that: (1) the Vernes method is an improvement on all flocculation tests where the optic density is measured by the unaided eye; (2) the Vernes method of diagnosis agrees with the Wassermann reaction in the great majority of cases; (3) the Vernes method is superior to the Wassermann reaction for the control of treatment; (4) the Vernes photometer affords a rapid and convenient method of estimating the albumin content of the cerebro-spinal fluid.

With such a consensus of opinion in Europe and America the neglect of the majority of the medical laboratories of this country to explore an apparatus and technique that claims to afford the observer an accurate estimation of flocculation is remarkable. No doubt the cost of the photometer, mixer, water baths, and other apparatus which, with import duty, exceeds £100, is one reason why the test is so little known in Great Britain, where most laboratories do not possess any research fund. This test has received very little publicity in English medical literature, and consequently there are many, even in the front ranks of our profession, who have never heard of the test, although a fairly bulky foreign literature on the subject is accumulating. The superiority of the Vernes test over the Wassermann test has not yet been proved here, but neither has it been disproved. The Vernes method certainly deserves a wider investigation in this country than it has hitherto received.

WORK OF EYE HOSPITALS.—The annual report of the Wolverhampton and Midland Counties Eye Hospital shows that last year there were 12,920 new patients, of whom 769 were in-patients, and that 6880 accidents were treated. In the ultra-violet ray department there were 4221 treatments, nearly double the previous year's number. The Bradford Eye and Ear Hospital is to be enlarged, and the operating theatre, intended for three operations a day, whereas now the average exceeds ten, modernised. Last year there were 3280 operations and nearly 37,000 out-patients' attendances.—Extensions of the Sussex Eye Hospital have been approved which will provide accommodation for 50 patients. The out-patient department is to be enlarged and appliances modernised, and it is hoped to provide beds for paying patients. The work will cost £25,000.

IODISED TINCTURE OF GUAIACOL

IN THE TREATMENT OF SYNOVIAL AND SEROUS AFFECTIONS.

By JOHN MABERLY, M.R.C.S. Eng.

THE preparation tinctura iodo-guaiacol contains in solution an iodine addition-compound of guaiacol, C_6H_4 OH.OCH_3—the methyl ether of pyrocatechol. Efforts to produce it in a dry state fail because secondary changes occur during the attempt: therefore no empirical formula can be assigned to it. One fluid drachm of the tincture contains one-fortieth of a grain of iodine in organic combination. In vitro iodine is one of the most powerful germicidal or antiseptic agents we possess. In vivo, however, none of the saturated inorganic pharmacopœial preparations exhibit any marked internal antiseptic action. From a chemical point of view potassium iodide seems peculiarly fitted to act as a carrier of iodine to the system. The atomic weight of its two elements—potassium 39 and iodine 127—means that in administering eight grains of potassium iodide we are apparently giving rather more than six grains of iodine, equivalent to half an ounce of the tincture. It is quite evident that its capacity to set free iodine in the system in a form in which its antiseptic properties are active, potassium iodide must be virtually inert. It was with the idea of obtaining some unsaturated organic form of iodine which could be taken by the mouth and would exhibit some of antiseptic properties of iodine in the system that the tinctura iodo-guaiacol compound was constructed.

The object especially in view was the treatment of pulmonary tuberculosis. The fact that guaiacol apparently had some beneficial action as an internal antiseptic in that disease suggested that its combination with iodine might give more definite results. Administration of the compound in several advanced cases of pulmonary tuberculosis over periods varying from one to eight weeks made it clear that, although the drug was non-toxic, it had no definite antiseptic action, at any rate in the finer lung tissue. Its use in place of potassium iodide in the class of cases in which I had been accustomed to use the latter drug, such as gummata and late neuro-syphilitic affections, proved that it was more efficient. In children with a tendency to enlargement of the tonsils and adenoids, which we now look upon as being probably dependent on a deficiency in thyroid extract, the tinctura iodo-guaiacol also appeared beneficial. Some interesting results in South Africa suggested that the drug had antiseptic action in the serous fluids and membranes, and experimental administration in pleurisy and synovitis confirmed this idea.

Cases of Pleurisy.

The following case of acute pleurisy is a good illustration of this action:—

The patient, a well-built man of 24, was seen on Sept. 24th. He had been suffering for two days from an acute feverish attack with a series of rigors, dry cough, and very severe pain in the right chest on breathing and coughing. He gave history of exposure to rain and cold. His temperature was 102·6° F.; breathing rapid and shallow. The breath sounds were obscured over the front of the right chest and the percussion note was dull from the fifth interspace downwards over a limited area, with some friction sounds just below the nipple line. Tinctura iodo-guaiacol, one fluid drachm to half an ounce of syrup and water, was ordered to be taken every eight hours.

Sept. 25th: The patient was distinctly easier, and stated that the rigors had ceased and the pain was very much less. His temperature was 100°.

26th: The temperature was 98·6°; the pain had gone. The breath sounds were still somewhat obscured but were audible over the dull area.

28th: The temperature was 98·2°. All signs of pleurisy had disappeared. The patient was allowed up the next day and no further medical attendance was required.

In my lung ward at the military hospital at Roberts Heights in 1917 and 1918 five cases of dry pleurisy came under treatment among malarial patients from East Africa. The symptoms in each case were typical, with dull patches, obscured breath sounds, friction, and pain on breathing. The temperatures were variable on account of the presence of malaria. All these cases cleared up rapidly on administration of one drachm doses of tinctura iodo-guaiacol, given three times a day for the first 24 hours and then twice a day. Relief from pain was obtained within 24 hours and the physical signs disappeared in three or four days. During the last two years similar rapid relief from pain and symptoms has been obtained in patches of pleurisy among sanatorium patients suffering from pulmonary tuberculosis in England. In pulmonary tuberculosis especially one meets with cases in which there are old, permanently adherent patches of pleura which are subject to acute attacks occasionally. In these, although the pain and signs of active microbic infection quickly disappear, the dull patch of adhesion remains.

Whilst I was on military service more than one case of pleurodynia was sent into my wards diagnosed as pleurisy. This rheumatic form of nerve muscular affection does not come under the action of the tinctura iodo-guaiacol, but the preparation has proved curative in uncomplicated cases of acute pleurisy with effusion and also in the dry type. Cases which come under treatment after a definite amount of effusion has taken place naturally take longer to clear completely than do those in which the treatment is undertaken at an earlier stage. The resolvent action of the drug may, I think, be relied upon to create absorption in most cases without surgical interference. Where evacuation of the effusion seems necessary, aspiration or evacuation by simple incision, with immediate closing of the wound, is all that is necessary; the antiseptic and resolvent action of the drug should then be effective in completing the cure. If the pleura is left open and drained of its fluid, the drug fails to act so satisfactorily.

In many cases, especially in England, acute pleurisy is complicated with an unhealthy condition of the adjacent lung tissue, usually of a septic or pneumonic type. In these cases the results of administration of the tinctura iodo-guaiacol are not so satisfactory or definite as in the uncomplicated cases. The drug has no disinfectant action in the finer lung tissue and, although the pleura will improve, the lung condition with cough and temperature may continue. In two cases of pneumothorax, one tuberculous and the other non-tuberculous, the results were very satisfactory. Healing and resolution took place in a very short time.

In the treatment of synovitis and teno-synovitis of septic and tuberculous types similar antiseptic and antiphlogistic action has been evident.

Tuberculous Synovitis of the Dorsal Vertebræ.

This patient, a married woman of 28 with one child, had been suffering for two years from intermittent attacks of pain about the region of the third and fourth dorsal vertebræ. It had gradually been getting worse and threatened to incapacitate her. She had been in Cape Town hospital for three months and the diagnosis had been confirmed by the tuberculin test. When she returned home the symptoms recurred as soon as she attempted to get about and do any work, such as using a broom or her sewing machine. There was marked pain on palpation and percussion over the spines of the third and fourth dorsal vertebræ. I prescribed tinctura iodo-guaiacol, one fluid drachm in half an ounce of syrup and water, to be taken twice a day. The pain steadily diminished and at the end of a fortnight both the pain and tenderness on pressure had entirely disappeared. She continued taking the drug once a day for another fortnight. During the next two months she gained a stone in weight and was quite free from symptoms. She stated that the first three doses produced an almost immediate reaction, a peculiar sensation at the painful part and a general reaction "similar to the effect of a stiff tot of brandy." It lasted about ten minutes and did not recur after the third dose.

Septic Inflammation of the Knee-joint.

The patient, a boy of 8, had fallen in the road and suffered from a contused open wound over the left knee-joint. This was disinfected and the wound sutured. The wound

remained healthy but three days later the synovial membrane was painful and swollen. Tinctura iodo-guaiacol, one fluid drachm every 12 hours, was ordered. The pain and swelling disappeared during the next three days and the child was allowed to get up four days later and had no further trouble.

Other cases of tuberculous and septic types of synovitis have at various times come under treatment, and in each case the same antiseptic and healing action has been obtained. The drug was tested in advanced tuberculous disease of the spine and hip-joint in which suppuration and disease of the cartilages or bones was present. In these cases it completely failed to have any definite effect. Its therapeutic action has proved to be confined to the synovial membranes only; when once the disease has extended to the other tissues, it has no longer any curative action. The same want of any definite disinfectant action is found if a synovial membrane such as that of the knee is opened and kept drained of its fluid, as in the case of the pleura. The antiseptic action, both in the pleura and synovial membranes, apparently depends on the presence of the serous or synovial fluids and the integrity of the membranes. It is not evident in the blood or other tissues of the body with the exception of the ciliary membranes. In traumatic inflammation of the joints, and in sprains about the joints and tendons, the tincture has a rapid antiphlogistic action. The pain and inflammation disappear after administration of the drug, though the effusion may persist for a variable time.

Conclusions.

The uniform results obtained in a fairly large number of cases of pleurisy and synovitis of various types justifies the conclusion that in tinctura iodo-guaiacol we have a drug which has a definite selective antiseptic and antiphlogistic action in these membranes, provided they are closed, and one which fills an important gap in our materia medica for the treatment of septic, tuberculous, and traumatic inflammation of those membranes. It also exhibits the well-recognised resolvent effect of iodine.

The therapeutic effects of the tincture in the pleura and synovial membranes suggests that a similar action would be present in the other serous membranes and spaces, such as the cerebro-spinal and peritoneal. A limited experience of the use of the drug in meningitis, and in syphilitic and other infections of the cerebro-spinal system, supports this contention and further work on these lines appears very desirable. In the cases in which I have used the drug with apparent success lumbar puncture was not performed. In three cases of severe meningitis treated by another observer, lumbar puncture and the instillation of medicated serum was performed before and during the administration of the tincture. The results were completely negative. In any future work on these lines I would suggest that lumbar puncture should be avoided. It seems most likely in the case of a drug which only acts in a certain environment that any interference with that environment would nullify its action.

Dosage.

One fluid drachm given twice a day is sufficient in ordinary adult cases. In acute or dangerous conditions two or more drachms have been given every four hours for two or three doses. After that the smaller dose given once or twice a day has been found sufficient. Children are tolerant of the drug and take half to one drachm given in a similar manner. The addition of a little simple syrup to each drachm of the tincture, and water to half a fluid ounce is not an unpleasant mode of administration. Chloroform either alone or in solution is quite incompatible.

It is very difficult in general practice, without the facilities of a hospital and skilled laboratory help, to carry out to a satisfactory conclusion any therapeutic investigation, especially if the results are unexpected. One has to wait a long time for suitable cases, and when they do occur they are not under the skilled supervision which is desirable for scientific records.

Note.—The British Drug Houses, Ltd., have undertaken to place the preparation at the disposal of the medical profession.

Clinical and Laboratory Notes.

A CASE OF DISLOCATION OF THE RIGHT INNOMINATE BONE,

ASSOCIATED WITH LACERATION OF THE RIGHT KIDNEY.

By Richard Warren, M.D., M.Ch. Oxf., F.R.C.S. Eng.,
SURGEON TO THE WESTON-SUPER-MARE HOSPITAL.

Owing to its rarity this case seems worth recording.

The patient, a man of 21, was thrown from his motor-bicycle on March 11th, 1927, and crashed violently on his right side and hip. On admission he was in a condition of severe shock, pale, and almost pulseless. There was bruising of the right flank with rigidity and swelling. The right side of the pelvis was loose and there was an obvious hiatus in the region of the symphysis pubis. The pelvic condition was at first thought to be a fracture of the pelvis and a catheter was passed to ascertain whether the urethra was ruptured; bloody urine was drawn off but the urethra was intact. The pelvis was steadied with a firm binder and the patient treated for shock. The condition of shock persisted for several days and a large swelling was present in the right loin. It was daily debated whether it was advisable to explore the right kidney which was evidently

Radiogram showing displacement upwards of the whole right os innominatum.

lacerated, but conservative counsels prevailed—at first because it seemed that the least further interference might cause his death, later because he seemed to be getting better without.

The urine cleared and the renal hæmatoma slowly subsided. In a few days his condition permitted of taking a radiogram (here shown), when it was found that the symphysis had separated and the right sacro-iliac joint had given way. Attempts were made to bring down the ilium by weight extension and to draw the pubes together with a hip-band and elastic traction. It is pretty clear, however, from the later radiograms that but little was accomplished in this direction, although the gap between the pubes appeared on palpation to be much diminished when he left hospital. In February, 1928, he could walk some miles and had hardly any limp is now perceptible. The sacro-iliac joint is firmly united and there is calcified material (? bone) between the separated pubes.

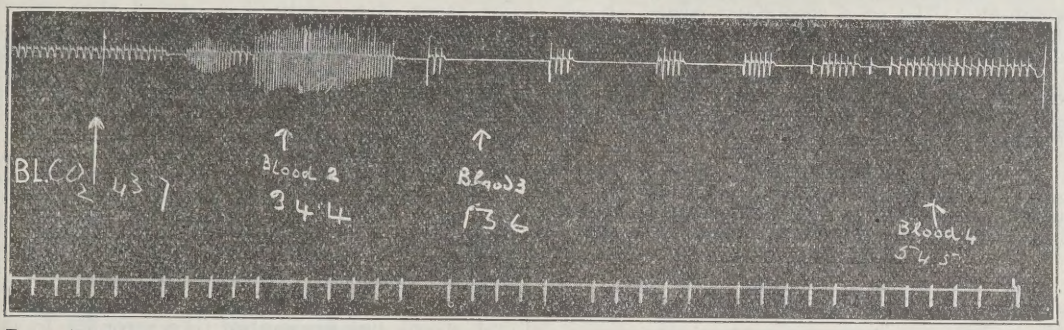
Thus treatment, which in the light of X ray finding seems to have been inadequate, has ended in a useful functional result.

RESPIRATORY ACTION OF LOBELINE IN THE DOG.

BY SAMSON WRIGHT, M.D., M.R.C.P. LOND.,
AND
F. R. CURTIS, M.Sc., M.B. LEEDS.
(From the Department of Physiology, Middlesex Hospital and King's College.)

IN continuation of our previous studies [1] we have made a more detailed quantitative examination of the respiratory action of lobeline in the dog anæsthetised with chloralose. The tracheal cannula was connected to respiratory valves of low resistance, which enabled the expired air to be collected at appropriate intervals in a series of Douglas bags; continuous sampling of the alveolar air was carried out by the automatic method of Wright and Kremer.[2]

From the results summarised in the table, it is clear that doses of 0·15 to 0·4 mg. lobeline per kg. body-weight produce, as a rule, in the dog under chloralose anæsthesia a marked initial stimulation of respiration. The minute pulmonary ventilation may increase five to ten times and in one case nearly 20 times; this result is due mainly to an increase in depth and to a less extent to acceleration of the breathing. The alveolar CO_2 may decrease by 1·4 to 3·7 per cent. of an atmosphere; as these figures represent the average composition of the alveolar air throughout the initial hyperpnœa, it follows that the level of alveolar CO_2 per cent. at the end of this period must be even lower than the figures noted.



Dog. Chloralose respiration. Intravenous injection of 3 mg. lobeline. Initial hyperpnœa followed by apnœa and Cheyne-Stokes breathing. Blood collected at points marked with arrows. Time in 10 secs.

The period of hyperpnœa in most of the observations is from 1 to 2·5 minutes; the CO_2 expired per minute may be two to four times the resting amounts. The total amount of CO_2 exhaled during this phase may thus be as much as eight or ten times the amount excreted during a control period of similar duration.

VII. (kg.)	Control.	22	9·5	0·43	—	4·1	2·8	12	129 c.cm. excess CO_2; alveolar CO_2 collected during last 30 secs. of this period. Hyperpnœa was followed by 7 min. apnœa and then breathing resumed.
	3 mg. lob.	1.10″	9·65	8·3	—	1·5	1·7	141	

The hyperpnœa is, however, usually transitory and the ventilation rapidly decreases and soon falls to normal or below normal. In some instances apnœa may set in quite suddenly (and lasted 7 minutes in one instance) or Cheyne-Stokes breathing may develop (see the tracing which is here reproduced). During this period of respiratory depression CO_2 retention occurs and the alveolar and blood CO_2 levels begin to recover. Thus in the tracing the initial blood CO_2 (in volumes per cent.) was 43·7, after 1 minute hyperpnœa 34·4, soon after the end of the hyperpnœa 13·6, and when normal breathing was restored, following the phase of irregularity, 54·5. The alveolar CO_2 may rise however, though the ventilation remains above normal.

In some instances the initial hyperpnœa may be prolonged (dog VI.) or a secondary period of over-breathing may set in (dog III.).

The initial effects reported here are similar to those observed by ourselves [1] and Smith [3] in intact, decerebrate, or morphinised dogs; the secondary depression noted seems to be related to the presence of chloralose anæsthesia.

A CASE OF AGRANULOCYTIC ANGINA.

BY LINDSEY W. BATTEN, M.B. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL.

Agranulocytic angina is a name first used by Schultz in 1922 to describe a symptom-complex whose essential feature is the association of a septic inflammation of the tonsils, pharynx, or mouth with a profound and increasing leucopenia, affecting especially the polymorphunuclear cells.

Acute onset, fever, and pronounced toxæmia appear to be constant features of the condition, and only less constant a failure to react to treatment and a fatal termination. Since 1922 a considerable number of cases presenting these features have been reported, chiefly by German and American observers, and the condition finds a place in American text-books of medicine. It is briefly mentioned in the third edition of "Osler and McCrae," but is not alluded to in other standard English text-books, and no case, at least under this title, appears to have been recorded in this country.

The nature of the condition has been discussed by several writers, among them Kastlin,[1] of Toronto, who reviewed 43 cases, reported by some 18 separate observers, and described in detail two cases of his own with the findings at autopsy. L. K. Gundrum,[2] of Los Angeles, reviewing the subject in March, 1928, mentions 47 collected cases, of whom 43 died.

No evidence that the condition is due to a specific organism is forthcoming. Smears and cultures from the mouth have generally shown a mixed infection, the bacillus of diphtheria and Vincent's organisms being absent, and although blood culture was positive in 9 of the 43 cases reviewed by Kastlin, the organisms grown were of four different kinds: hæmolytic streptococci, *Bacillus pyocyaneus*, staphylococci, and *B. coli*. On the evidence of these facts and of certain variations in symptomatology, Kastlin concludes that the condition is not a clinical entity, but that "the factors that bring about the clinical state must depend on an inconstant individual reaction to the etiologic agent." This may well be, but it is clear that the cases have a very strong family likeness and the clinical picture seems sufficiently clear to deserve a descriptive name pending further analysis. It cannot possibly be classed among the "terminal infections."

[1] Kastlin, G.: Amer. Jour. Med. Sci., 1927, n.s. clxxiii., 799.
[2] Gundrum, L. K.: Arch. Internal Med., 1928, xli., 343.

In addition to the essential features of the syndrome already mentioned, a number of inconstant symptoms have been described; but, with the doubtful exception of jaundice, which was present in 58 per cent. of Kastlin's cases, they are all such as may occur in toxæmic or septicæmic states, of whatever origin.

The distinguishing mark of the condition is the extreme leucopenia. Kastlin states that in two cases an initial leucocytosis has been observed, but within a day or two of onset a count of 1000 to 2000 white cells per c.mm. is usual, and this continues to fall, counts of 500 or fewer per c.mm. being not uncommon, with 100 as the lowest count recorded, while the percentage of polymorphonuclears falls to 15, 5, or even 0 per cent. in differential counts. In the few cases of recovery it is stated that the blood-picture has returned to normal. If the condition is to be ascribed to an abnormal reaction to an "ordinary" infection, the type of patient attacked, previous history, and state of health at the time of onset are of obvious importance. The patient is typically, but by no means always, a woman, and middle aged. Of Kastlin's 43 cases, 78 per cent. were in women, 22 in men. The youngest patient was 18, the oldest 74, the average age of the women was 46 and of the men 29. In 28 cases the disease occurred during good health; in 15 after a longer or shorter period of impaired health due to a variety of causes. Seven of the 43 had had previous oral infections, and one case is on record of a patient who recovered from first attack but succumbed to a second. In none of these cases is there a history of preceding asthma or other "allergic" disorder. In all cases the onset, whether during good or impaired health, was acute with high fever.

At autopsy the only characteristic feature is, apparently, a hypoplasia of the bone-marrow "with almost total absence of granulocytic cells" (Kastlin), the other findings being those associated with death from toxæmia or septicæmia. A broncho-pneumonia in which the alveoli were filled with fibrin, serum, and red corpuscles, leucocytes being absent, was found in one of Kastlin's cases, and it seems probable that pneumonia, when it supervenes, would be of this type.

The case that follows presents the essential features of the syndrome and in all respects very closely resembles many of the recorded cases.

The Case Described.

The patient was a lady of 50, the mother of ten healthy children, and a very capable mistress of a large household. For the last eight years she had had a mild chronic asthma with occasional acute attacks. These responded well to adrenalin, but she was rarely free from slight asthma or dyspnœa. In other respects she had good health and had not before showed evidence of defective resistance to infection. During the last six or eight months she had had more than her share of anxiety and worry for various domestic reasons, and in August, 1928, while away on holiday, she had an attack of acute pharyngitis with fever, but recovered without incident. No blood count was done on this occasion. At the end of October she was troubled with neuralgic pains in the head but appeared otherwise to be in her usual health. On Nov. 7th, in the evening, she felt chilly and ill and went to bed, taking a tablet of one which had been prescribed for her in her previous attack of pharyngitis. In spite of this she spent a wakeful night, and I was called to see her on the morning of the 9th. She was then very drowsy, out of proportion to the hypnotic taken. Her temperature was 102·8° F., pulse-rate 120, respiration-rate 32, and the breathing slightly asthmatic. Herpes was present on the lip and left nostril. The mouth was dry with sticky mucus between the tongue and palate, the pharynx was red and swollen, the tonsils especially so, a little white exudate was present on the right tonsil, and the tonsilar glands were palpable and slightly tender.

The heart and lungs showed little abnormal, the urine a haze of albumin. A swab was taken of the tonsilar exudate and sent to a pathologist, who reported in the film streptococci, Gram-positive and Gram-negative bacilli, and a few spirilla (the latter not typical of Vincent's angina), and in culture non-hæmolytic streptococci and diphtheroid bacilli but no *Bacillus diphtheriæ*.

Fever and drowsiness with inability to sleep continued, the throat became sore, and shallow ulcers began to form on the tonsils. On the evening of Nov. 10th a raised, blotchy

ythematous rash appeared on the buttocks and backs of e elbows and spread rapidly over the legs, arms, and fore- ms, with a simple erythema of the palms of the hands. he rash came out quickly and then partly faded, but turned later in the illness.

The blood was first examined, after a consultation, on ov. 11th. The count showed: red blood cells, 3,800,000. r c.mm.; hæmoglobin, 68 per cent; colour-index, 0·9; hite blood cells, 2100 per c.mm.; polymorphonuclears per cent.), 20 per c.mm.; lymphocytes (93 per cent.), 50 per c.mm.; large mononuclears (6 per cent), 130 per mm.; no eosinophils or basophils. No abnormal red or hite cells seen. Blood culture was negative, and a second roat swab confirmed the results of the first.

From this on, the disease ran a slowly progressive course. ever continued, ranging from 100° to 103° F., the allow tonsillar ulcers extended and involved the right ucial pillar with, later, a small ulcer on the tip of the ngue, the tonsillar glands remained slightly enlarged and nder, but there was no attempt at suppuration, no œdema the neck, no dyspnœa, and no marked dysphagia. The buminuria increased somewhat and was accompanied granular casts. The herpes labialis increased. Inability sleep and discomfort in the nose and throat were the tient's chief complaints; she appeared gravely ill, but ok nourishment well and did not lose flesh.

A second blood count on Nov. 15th, 18 hours after a ood transfusion of 400 c.cm., showed: red blood cells, 960,000 per c.mm.; white blood cells, 500 per c.mm.

On the evening of Nov. 17th an abrupt rise of temperature 104·4° F., with rapid breathing and the expectoration of thick, ropy sputum seemed to indicate the onset of pneumonia, but no corresponding physical signs were found then or later in the chest. A film of the sputum showed inspissated mucus with a minimum of cells. No jaundice, hæmorrhages, petechial or other, or enlargement of spleen or liver appeared.

Treatment, except in the alleviation of symptoms, appeared to be entirely without effect. At an early stage a sensitised streptococcal vaccine was given in doses up to 500 million daily, two blood transfusions, one of 400 c.cm. and one of 500 c.cm. were given, but without reaction or apparent benefit; paints, sprays, and gargles did not appreciably alter the condition of the throat. Antistreptococcal serum was at first withheld for fear of producing anaphylactic shock in an asthmatic subject, but was ultimately given in doses rising to 10 c.cm. three-hourly, without reaction or effect. Such signs of asthma as occurred were easily controlled by adrenalin, and sleep was secured by injections of omnopon. The patient became increasingly exhausted and drowsy and died on Nov. 20th after 12 days' illness.

The case described is typical of the condition known in Germany and America as agranulocytic angina. Since its recognition depends on the blood count, and the disease is not of a kind generally admitted to hospitals, it may well be less uncommon than the literature suggests. This case is reported in the hope that others will be recognised and noted and light ultimately be thrown on the ætiology and treatment of this obscure disease.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

At a meeting of this Society held on Feb. 25th, r. J. Walter Carr, the President, being in the air, Prof. A. H. Burgess (Manchester) introduced a scussion on

Acute Intestinal Obstruction.

ne present century, he said, had seen a great provement in the surgical treatment of acute dominal crises; this applied to nearly all groups, t least of all to acute intestinal obstruction. Manchester Royal Infirmary the mortality from ute appendicitis in 1924 was only one-twelfth what was in 1900; that from perforations of duodenal d gastric ulcer was only one-seventh in the later ar of what it was in 1900, whereas the mortality m acute intestinal obstruction had only been luced by half in the same period. Mr. H. S. Souttar d lent him the figures compiled for the British edical Association meeting in 1925, the largest ailable on the subject. It represented five years' tistics of seven hospitals—three in London, three the provinces, one in Ireland. He hoped Mr. uttar would compile a similar table at the end of 29; these would be classical for another decade.

Mortality.—For the purposes of the present dis- ssion Prof. Burgess omitted from these 3064 cases strangulated hernias and the acute intussuscep- ns. There was no excuse nowadays for anyone ssing a case of obstruction from strangulated nia; nor, indeed, of acute intussusception. More- er, the latter was not primarily an obstruction; the ject of early treatment was to prevent obstruction llowing the intussusception. Excluding those, there re left 1042 cases, giving 395 deaths, or a percentage rtality of 37·9. It was this mortality that surgeons re out to reduce, the death-rate of cases of the dition which were not readily obvious, and in ich there was some excuse for not making an mediate diagnosis. At the Royal Infirmary, nchester, from 1913 to 1922, the mortality was 1 per cent., while in 1925–27 it was 30·2 per cent. What was the reason for this high mortality? He not doubt that the main reason for it was delay carrying out the only treatment which could do d, the surgical. Still too many cases were being n only after the onset of a marked distension and toxæmia, when there existed what was termed fæcal vomiting. He contended that the early signs of acute intestinal obstruction had not been sufficiently stressed in the text-books, or at least not until the more recent ones were published. Too much stress was laid on the presence of fæcal vomiting as a sign of the condition; but that was not so much a symptom as an end-result. There was a tendency on the part of many to wait for the development of fæcal vomiting before diagnosing intestinal obstruction. The man who waited for the perfect clinical picture would rarely save his patient.

Primary or Secondary.—Acute intestinal obstruction might be either primary or secondary; in other words, it might occur as a bolt from the blue, or be a process engrafted upon a previously existing subacute or chronic condition. In the latter were two features which were never present in the primary. One of these was that it was frequently possible to see the outlines of individual dilated coils of intestine, and to see peristalsis. Sudden, acute obstruction always led to dilatation and thinning of the wall, never to visible peristalsis. Of course, in very thin people, such as those recovering from an exhausting illness, peristalsis could be seen apart from obstruction, but then it was occurring in normal-sized coils. When a peristaltic wave could be seen passing dilated coils, one could be sure it was a case of obstruction which had existed at least several weeks. Even when peristalsis was not actually visible, it could often be made evident by keeping the hand on the abdomen; a coil could be felt to be alternately hardening and softening. Primary acute intestinal obstruction varied in acuteness of onset. It was very acute in internal strangulation, or intussusception, or volvulus. In other types its development might be somewhat slower. Only in types associated not only with obstruction to the lumen of the bowel and interference with the blood-supply was the onset really acute; the latter factor was by far the more important. Fæces could be arrested for days, even weeks, but no patient could go on long with complete arrest of circulation. In general terms, the higher in the bowel the seat of obstruction the more acute were the symptoms, the only exception to that being the case of volvulus of the sigmoid, in which there was associated damage to a large extent of mesentery.

Early Symptoms.—The early symptoms of acute primary intestinal obstruction were those common to any other acute abdominal crisis; they were described many years ago by Sir Frederick Treves under the term "peritonism." They were, however, of no localising value. In this acute condition the pain

was always referred to the epigastric region, and hence it did not indicate the seat of the trouble. Often the pain was paroxysmal at first, and as the obstruction became complete, pain became continuous. The vomiting was, at first, entirely of a reflex character; later it was due to mechanical obstruction. The higher the site of the obstruction, the earlier did vomiting set in. Vomiting was a marked symptom when there existed high jejunal obstruction. When it was quite low down in the bowel vomiting might be absent throughout. True fæcal vomiting did not occur in acute intestinal obstruction, only when there was a fistulous communication between the colon and the stomach. Vomiting of true fæces, however, had been described apart from any obstruction at all. The important point about the vomiting was not so much its character as its persistence. Early in the case the cessation of the passages of fæces and flatus might not be absolute, because at the moment of obstruction the portion of intestine below the obstruction might contain quantities of fæces, and one, or even two, enemata might bring away fæces and gas. Unless this was borne in mind, the nature of the case might be missed.

The other symptom was active distension. Distension of a coil above the site of the obstruction must be present in every case of obstruction, though it was not always visible. The vomiting and the distension varied inversely. Another point about the distension was its shape. When it occurred in the sigmoid, there was the characteristic flattening of the flanks and the barrel-shaped abdomen; when the obstruction was in the small intestine, one found a prominent central distension. Volvulus of the sigmoid was an exception, for there, though the obstruction was low down, distension came on very rapidly. This distension was the most unfavourable feature in connexion with intestinal obstruction; it rendered operation more difficult, increased the degree of shock, and rendered it almost impossible to prevent collapse of the bowel.

Palpation might sometimes reveal the presence of a tumour in acute intussusception and in malignant disease. There was marked tympanitic resonance over the distended portion. He made a plea for auscultation of the abdomen, as he had found it of great value in the diagnosis of intestinal obstruction. There were certain sounds, which could not be mistaken, indicating the passage of fluid contents in a distended cavity which contained a considerable amount of gas, a kind of bell-tinkling sound.

Rectal examination was very important; if there existed a stricture or growth in the rectum, it could be felt, and sometimes through the rectal wall one could feel a mass in the sigmoid which had prolapsed into the pelvis. Frequently ballooning of the rectum could be made out, it was often associated with a growth in the upper sigmoid region. When obstruction was suspected in the large intestine, sigmoidoscopy should always be carried out; the instrument could be passed 9 to 11 inches, and, from a negative point of view, it was valuable to be able to say that within that area there was no obstruction.

Site of Obstruction.—With regard to diagnosis of the site of the obstruction, sometimes a palpable tumour in the abdomen furnished the guide; or if the case should be seen early enough, one might be able to say where the local distension started. Mostly, when the case was seen, there was no such guide, and all one could determine was whether the obstruction was in the large or the small intestine. In Mr. Souttar's list there were 586 cases in the small intestine, 433 in the large; roughly, the chances favoured the obstruction being in the small rather than in the large bowel. When the medical history revealed previous indigestion or obstructive troubles it strongly favoured the obstruction being in the large intestine; when the obstruction occurred suddenly, the site was more likely to be the small bowel. The key to the position was the condition of the cæcum. If the obstruction was in the colon, the cæcum must be distended, unless there was a growth of the cæcum itself; then it would be palpable. If the obstruction was in the small intestine, the cæcum must be prolapsed. Often before operation it was possible to say whether one was dealing with colonic or small intestine obstruction. If obstruction could be definitely located to the large intestine, it was 9 to 1 chance that the case was one of malignant growth. If one could determine that the obstruction was in the small intestine, the odds were 300 to 1 against it being malignant growth.

Treatment.—With regard to treatment of true mechanical obstruction (he omitted paralytic ileus) there was really only one treatment—namely, the operative—though there were accessory methods, such as stomach lavage, and the exhibition of large quantities of fluid, as much fluid was lost in vomiting. And because of the loss of chlorides, hypertonic saline should be given. And anti-gas-gangrene serum was valuable, because many of the symptoms were due to *B. welchii*. Another treatment was by enemata of bile. The nature of the operation would depend on the stage of the disease. Seen early, with but little distension, and the patient in good general condition, the treatment was ordinary exploratory laparotomy. Before the anæsthetic was given the stomach must be washed out, and if possible, spinal anæsthesia should be selected; controllable spinal anæsthesia had given better results in his hospital during the last nine months than any form previously used. He preferred the right paramedian incision, going straight for the cæcum, to see whether it was distended. Next, he removed the obstruction or short-circuited it, or made an artificial anus above the obstruction. If seen in a late stage, with much distension, the less one did, provided it was effective, the better. The patient could stand but little manipulation. He usually contented himself with doing a valvular or "blind" cæcostomy; it afforded relief, and the patient would not die of obstruction.

Discussion.

Mr. C. H. S. FRANKAU emphasised the necessity of differentiating between the two types of acute intestinal obstruction, that of gradual onset due to growth, and that in which the blood-supply of the bowel was interfered with by a band. When there was complete obstruction of bowel contents and no interference with the blood-supply, toxæmia intervened only at a later stage. In the case due to strangulation there was sudden pain, and shock was profound from the start. The rapidity of the acute symptoms was largely due to the rapid multiplication of anaerobic organisms. This was pointed out to him by the late Mr. Clinton Dent, who therefore advocated the injection of hydrogen peroxide after relieving the obstruction. He declared himself to be against the performance of "blind" cæcostomy. Only once had he done it in 18 years, and then it was not in a case of obstruction; the patient had uræmia and was blown up by constipation. At the post-mortem the suspected growth was not found. In obstruction due to a strangulating band, diagnosis in the early stage was often difficult; there was danger that the case might be regarded as colic or food-poisoning until too late. Obstruction by bands was the more likely diagnosis if the patient had had a previous operation on the abdomen. In acute intestinal obstruction the pulse steadily rose and the tongue rapidly dried. A succussion splash could be elicited. During an attack of pain a coil of intestine could be felt to harden under the finger; if it was so hard when the patient vomited, that was confirmatory. An acute case caused by a band had a grim prognosis. In food colic there was never absolute constipation, and the intestinal movements were more marked than in some cases of intestinal obstruction. Anti-gas-gangrene serum was valuable, and it should be given in large doses. On the principle that it was unwise to flog a tired horse, he thought eserine, pituitrin, and similar drugs were best avoided. If drugs at

l were used, the best was magnesium sulphate in drachm doses, to assist the action of enemata. eus might follow injury, as after a fractured pelvis a gun-shot wound, or after a kidney operation which there had been a good deal of manipulation, after a fractured spine with a cord lesion. Another oup was the post-operative, in which there was no ıtecedent peritonitis and none subsequent to the peration. A third form of ileus was that which as a sequel to peritoneal inflammation. He referred the acute distension which occurred after removing gangrenous appendix. Ileus, the result of injury, as troublesome, and might be persistent, but it was rely fatal. It reacted to stimulants of the intestine, ch as eserine. He thought it probably followed terference with sympathetic plexuses. The second pe, after a simple straightforward abdominal peration, in which there was neither hæmorrhage r shock, and which was difficult to explain, was ore serious He thought it had something to do th the anæsthetic. Nowadays, anæsthesia was ore skilful, and patients got more oxygen, and the currence of this was rarer. Human bile given to e patient often had a dramatic result for good; d the actual cautery to the abdominal wall some-nes caused a profound effect. In a third type, in ıich ileus followed on definite peritonitis, fluid ould, if possible, be given by both mouth and rectum. ıch operations as lateral anastomosis did not appeal him.

Mr. HERBERT CARSON said it was well to remember at the higher the obstruction the more definite e symptoms, and the lower the obstruction in the wel the more definite were the signs. He agreed at the present death-rate from hernia and intus-sception was much lower than some years ago. hy, he asked, did people die of intestinal obstruc-n? He did not think that was known. In the e stage the patient had an extraordinary condition toxæmia, and at the end death came suddenly, nost unexpectedly. He thought it must be due absolute poisoning of the heart muscle. The privation of bile theory did not satisfy him, but illiams's gas-gangrene theory did to some extent, he had derived remarkably good results from using anti-gas-gangrene serum, and the wounds had aled up surprisingly quickly. In order to ascertain urately what killed these patients, he thought earches should be made into the condition of the od plasma. At the present time, in association h a pathologist at the Montreal General Hospital, angements had been made to examine the blood sma of cases before anything was done, and again er the operation, and after the administration of i-gas-gangrene serum, to see if, and in what y, it was altered. Until the actual cause of ıth was known, it would be difficult to find the ıedy.

Mr. T. H. C. BENIANS said his feeling was that the m toxæmia was one which was loosely used by geons generally. The toxins which worried were se which were of the neurotropic type, because en they had arrived in a nerve path they seemed be out of the reach of antitoxins. If, on the other ıd, the toxin was in the blood stream, antitoxin ıtment was much more hopeful. He had been king at the subject from the point of view of oxicating diphtheria.

Mr. ZACHARY COPE spoke highly of the value of i-gas-gangrene serum in cases of intestinal obstruc-ı, even in fæculent vomiting in post-operative s. The condition had got well without ileostomy. such case he would have given four hours to live, decided to give the serum, and after two doses dirty sloughy condition cleared up and the patient well. He urged a careful noting of the patient's tolic blood pressure when estimating what could ndured in the way of operation, paying special ntion to the difference between the systolic and diastolic.

Mr. HOPE CARLTON spoke of a sign he had ned abroad was that in primary pneumococcal or streptococcal peritonitis there was a great increase in the conduction of vocal sounds from the chest through the abdomen as heard over the symphysis pubis.

Mr. A. E. ROCHE thought cases of intestinal obstruction would be brought earlier under active treatment if there was less concentration on thinking in terms of distension and late vomiting. Rutherford Morrison's rule was, that if peritonism occurred, as shown by sudden acute abdominal pain, with nausea and vomiting, and had existed six hours—other conditions such as tabes and colic being excluded—it was an indication that something serious had happened inside the abdomen. Pulse indications were not always devoid of fallacy, and it was possible to wait too long for the supposed characteristic pulse.

Mr. DICKSON WRIGHT discussed the desirability of washing out the stomach with sodium bicarbonate. Steps taken to overcome alkalosis were the administration of ammonium chloride and the giving of hypertonic saline solution, either intravenously or per rectum.

In his reply Prof. BURGESS defended his attitude towards the performance of blind cæcostomy in patients whose condition was precarious owing to intestinal obstruction.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

A MEETING of this Section was held on Feb. 26th, the chair being taken by Dr. ROBERT HUTCHISON, Vice-President. Prof. KARL HANSEN (Heidelberg) read a paper on

ALLERGIC AND PSYCHICAL FACTORS IN ASTHMA.

Asthma, he said, was a clinical term embracing a whole distinct symptomatology and implying neither uniformity nor specificity in ætiology. After excluding the similar forms—cardiac, uræmic, and hysterical asthma—clinicians considered bronchial asthma as a pathogenic entity, characterised by spasms of the bronchial muscles and increased exudation, symptoms which were now known to be the expression of an aggravated excitement of the parasympathetic system. Recent researches had shown that the cause of this neurosis of the vagus lay deeper and that an exogenous releasing physical factor could be made responsible for many cases. This factor was the allergen, the absorption and peculiar assimilation of which brought about the disposition to attacks and the attacks themselves. It was not yet known whether all cases of bronchial asthma had some allergic constituent, therefore non-allergic forms must be distinguished. The classification of bronchial asthma as an allergic problem was a most important step towards understanding its pathology, but it needed supplementing, and seemed destined to bring us nearer the solution of a deeper and more general problem—that of the biological psycho-physical unity of the person.

After outlining the history and theoretical foundations of allergy, Prof. Hansen said that the identification of a disease as allergic depended on (1) the exact anamnesis, (2) the positive result of the cutaneous reaction, (3) the passive transferability of the cutaneous reaction to healthy persons through the serum of the diseased person, (4) the inspection of the patient's environment and the proof of the existence of specific allergens in it, (5) the exposure experiment, and (6) the disappearance of symptoms after the removal of allergens from the neighbourhood of the patient. None of these signs was alone infallible, but careful correlation of them gave a high probability of correct analysis of the allergic factors at any given time. Undoubtedly most sedulous attention should be paid to the exogenous allergic factor, but

it was clear that the presence of allergens in the environment of human beings did not necessarily produce an attack of illness. Only about 1 per cent. of people seemed to have any disposition to allergic diseases, and the tendency was usually found also among their antecedents. The conclusion that they had inherited a particular constitution was, however, only partly true, since Bloch and Karrer had shown that nearly every human being could be forced to an allergic reaction with chemically pure primrose poison. The frequency of allergic diseases depended largely on the amount and concentration of the absorbed allergen. Nevertheless, even sensitive patients could at times stand the presence of allergens without manifesting any reaction. This might be ascribed to temporary immunity, as seen in animal experiments and as used in J. Freeman's therapeutic method, successful in 80 per cent. of cases. The hypothesis of temporary immunity, however, did not explain the apparently incidental and haphazard rise and fall of many allergic symptoms. Other factors had a determining effect, especially exogenous factors which were easily overlooked—the change in the specific conditions of the resorption of allergens. Often an illness began when new conditions of resorption occurred—e.g., a workman had used ursol for years for dyeing furs, but got asthma the day he first tried to apply it with a spray instead of a paint-brush. In spite of a correct estimation of the exogenous factors, however, some endogenous ones seemed to play a part e.g., acclimatisation and influences of periodicity.

The Significance of the Psyche.

By the study of the functions pathological physiology had extended the pathology of the organs to a pathology of the body which was affected by every disturbance as a whole. This pathology was bound to the principle of the physico-chemical unity of the functions, but in this was expressed a higher principle—that of the manifestations of life in an individual, the principle of the person. The person alone was in the proper sense the subject of observation and treatment. Every pathogenic research which aimed at being the "pathology of the person" must take into account the relations of the psyche to the body as well as of the physico-chemical functions. Obviously such a comprehension of the patient was liable to serious errors. There was no means of measuring the strength of the psychical excitation and no possibility of finding a psycho-somatic energy formula. Fixing the psychical factor in itself paved the way for all kinds of deception of oneself and others; how much more dangerous, therefore, was the interpretation of its range of influence. One could only build with the greatest care and judgment and take into consideration cases where the proofs of psychical influences were overwhelming. Could it be proved that psychical factors influenced the disposition to disease in the face of known pathogenic substance affecting the organs; if so, how was it to be understood? For such a study nothing was more suitable than the allergic diseases, the dependence of which upon psychic influences was well known. Asthmatics often gave evidence of a "nervous" constitution, and hypnotism might do away with attacks for a longer or shorter time. The investigator wanted to know whether the patients acquired through psychological influences a resistance to or a tendency towards the allergen which partly constituted the attack. Success had attended a few experiments in which patients inhaled allergen in the hypnotic state or were protected from attacks by post-hypnotic suggestion, but in each patient other indeterminable influences had been at work. More convincing was a case in whose life-history the dependence appeared as a compelling force.

Prof. Hansen then related the history of a woman of 49 who had had asthma since the age of 10 but only at certain periods of her life, while at others it had completely vanished. She was sensitive to horse-dandruff and bed-feathers and had emphysema, but no sputum. A survey of her psychological history showed that the illness always set in when a situation was created which awakened a severe inn conflict from which she could find no escape. Wh the crisis was over the attacks stopped, whether t patient had found a real solution or apparent reli through transference. Her dreams clearly expresse the position.

The Correlation of Psychic and Allergic Factors.

Might not the pathological symptoms be co sidered simply as expressive movements, independe of any organic cause? A pathology of the pers would never reject the question of the "meaning of a symptom. A number of neurotic symptoms h a meaning, often unconscious, and the discovery the meaning often gave a pathogenetically sufficie explanation for them. The problem, however, w somewhat different when the symptom was co nected with a distinct organic defect. It was by means always true that the proof of the organ defect alone could explain the dependent symptom for these varied in intensity according to "moods and had a psychologically expressive meaning. all cases of genuine idiosyncratic forms of disease must proceed with the greatest caution in evaluati the symptoms as specific expressions. This patie had been definitely sensitive to a common allerg but had only succumbed to attacks under t impression of certain experiences. That such expe ences gained a sensitising preparing power did n lie in their subject matter alone, but had its reas in the much more general biographical significar which they acquired in the particular situation of t person for his development. The problem of po choreic motility derangements was one of the sa kind. In asthma there was an ever-renewed intrusi of morbific germs (the allergen) into the organis but these agents only led to illness when they fou the body prepared by certain psychical experienc The aim of the paper had been to show that diseas the incitement of which was manifestly subject t pathogenic physical components, were also ab lutely dependent in their course, even in their orig on special psychical influences acting on the patie We could not yet say what organic links the m used to prepare the body, but the vegetative nerv system played a most important part. It was a system over which the will had no control and wh was particularly determinable by psychical influen The clinician could not go too far in analysing these threads, both psychic and organic, but would only get an incomplete view of the wh unless he recognised the principle of the biolog unity of the person.

Discussion.

DR. MILLAIS CULPIN said that attempts to corre the psychical and allergic factors in asthma w almost unknown. He recalled two cases simila that of Dr. Hansen. In patients subject to pat logical states of anxiety there occurred, in resp to specific or non-specific stimuli, attacks of *angs* anxiety (there was no exact English equivalent which the objective signs of extreme fear w manifested. In some patients the symptoms appea not as *angst*, but as attacks of cardiac or gas intestinal disturbance. Like asthma, they migh cured by elucidation of the significance of the stin or they might respond to any one of a multitud therapeutic measures, or disappear spontaneou The physical symptoms might act as the equivale anxiety; while the patient had cardiac, gas intestinal, or respiratory troubles he might be from sensations of fear. The psychologist hac explanation why one patient should develop *ast* another faintness and palpitation, another ner polyuria, and another asthma when some stim stirred up an emotion unfitted to the circumsta At present the allergic phenomena were to be i preted as freakish manifestations of a biocher Puck; any hypothesis that could correlate them other manifestations should be welcomed by chemists. Help in correlating them with ps factors might be found in Pavlov's studies of

onditioned reflex. In the presence of emotionally abile physiological reactions the setting up of a onditioned reflex might take place through allergic nechanisms. There was urgent need for coöperation ather than opposition between those working at lifferent aspects of this problem.

Dr. R. D. GILLESPIE said that psychologists in this ountry had not much opportunity of seeing sthmatics, and there were few references in the iterature to the purely psychological aspects. Psycho-enic dyspnœa was not asthma, and the asthmatic ype of dyspnœa was not part of the normal emotional eaction of *angst*. It seemed most probable that the sthmatic paroxysm was a constitutional peculiarity hat was set going by physical or psychical factors.

Dr. E. P. POULTON related two experiences suggest-ng a psychological factor in migraine, and Dr. . ORIEL described a mother who had developed rticaria while her daughter got angioneurotic edema after the former had been chased by her usband with a revolver. The daughter had at the ame time become egg-sensitive, but had lost this ensitivity when the parents had obtained a divorce.

Dr. A. CAWADIAS said he had seen asthma develop fter strong emotion, but the patients had reacted o allergens and had been cured by diet and auto-æmotherapy. The mechanism of correlation of sychic and allergic factors would probably be found hen our ideas of the vegetative nervous system were nore complete. There was probably a real organic eurological explanation of these cases—a fibre-onnexion between the cortex and the viscera.

Dr. PARKES WEBER said that it was difficult to et away from the fact that psychical factors nfluenced asthma—among other diseases. The eaction towards any psychic factor of disease epended partly on the nature of the factor, but also rgely upon the pattern of the individual, in many ases the pattern of the vegetative nervous consti-ution. The reaction varied according to the seed nd the soil, and was exactly analogous to the ffect of all physical agents, especially the milder athogenic ones. There was no reason why asthma ould be an exception to the general rule.

Dr. GEORGE GRAHAM asked what part adrenalin layed in the reaction.

Dr. HAROLD AWROUNIN said that the sympathetic ervous system must be associated with the asthmatic tack, acting, probably, on the finer capillaries as it d in angioneurotic œdema, urticaria, perhaps in igraine, and probably in mucous colitis. This was hy atropine and adrenalin were of value.

Prof. HANSEN, in reply, emphasised his opinion that finite sensitivity to certain substances only produced sthma if certain psychogenic factors were present, erefore the psychogenic factors influenced an illness organic origin. Many allergic phenomena that re attributed to psychical origin might be traced organic causes if research were continued. As any asthmatic reactions were not allergic at all, it as impossible at present to make any precise atement.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

A MEETING of this Section was held on Feb. 22nd, . G. E. WAUGH, Vice-President, taking the chair. . GERALD SLOT read a paper dealing with

THE WORK OF A RHEUMATISM SUPERVISORY CENTRE.

e had been impressed, he said, with the increasing portance of rheumatic fever in this country. ace the disease had been taken seriously among the hool medical services 9000 cases had been istered; probably there were 24,000 in London ne. Cases came to a clinic from four sources: erred by school medical officers through the care mmittee; from private practitioners—and these increasing numbers; by voluntary application of parents to the head teacher; and as ordinary -patients to a hospital. The duties of a rheumatism supervisory centre were: (1) The supervision of children suffering from rheumatic manifestations. (2) Recording on the school record card, or writing to the doctor or in some other way noting definitely whether or not the child was rheumatic. This was in many cases impossible, but at any rate the centre acted as a second opinion and was able to save unnecessary invalidism. (3) Instruction of parents on the importance of rest, modes of hygienic living, and the severity to the child's future of neglecting rheumatic disease. (4) The keeping of accurate records; these were usually based on Dr. Reginald Miller's schedule. (5) Arranging for treatment, whether by the private doctor, by a local hospital, or at one of the Metropolitan Asylums Board special hospitals, or in the local infirmary. In some districts the infirmary would arrange for continuing treatment under the doctor in charge of the centre. (6) Arranging for convalescence, and for reports from the convalescent home to complete the records. (7) Arranging the treatment of minor maladies, such as unhealthy tonsils. (8) Acting as a centre for research. The physically defective schools were an important element in the life of a rheumatic child, who could be sent to one of these on his return from the convalescent home. There he had no stairs to climb, education was not pressed, he could be taught a trade, and under statute law he could be kept until he was 16, so that his lost education was made up. The mortality before the age of 25 of cardiac children trained at physically defective schools was about 50 per cent.; of those sent to elementary schools it was about 80 per cent.

Method of Estimating Cardiac Efficiency.

The aim of a cardiac test was to secure some objective method of estimation which could be used to determine the efficiency of a heart on more than one occasion and by which a second observer could estimate the changes noted by the first. Vague terms and varied opinions made it very difficult to trace the history of a heart through other people's notes. The six factors taken were: reclining pulse-rate, standing pulse-rate, difference between reclining and standing pulse-rate, pulse-rate after standard exercise (touching the toes 20 times), time in which pulse-rate returned to normal, and difference between standing and reclining blood pressures. The fact that the nurse could take the pulse-rate obviated errors due to excitement at the doctor's visit. A system of marks varying from 3 to −1 was allotted to each test, so that a maximum of 18 could be obtained. Eight marks constituted a pass, 7 was doubtful, and below 6 some cardiac damage was indicated. The test was subject to the fallacies of all numerical tests, but had been based on a large number of cases, and it did give an index by which progress could be gauged from time to time. It was essential that the elements of a test should be obtainable in any bedroom, and elaborate clinical methods were therefore inadmissible. The test was especially useful in those cases where there was a rapid heart but nothing else. The heart that gave a poor response to the test often developed symptoms of damage later on. The scheme was put forward with all reserve and with no claim at all to finality.

Discussion of the Cardiac Test.

Dr. D. W. WINNICOTT described the points in which his rheumatism clinic at Queen's Hospital differed from that of Dr. Slot. They were particularly trying to avoid seeing too many children; they hoped to see a few very carefully and in time to be able to draw conclusions. He had not tried blood pressure estimations, but had found that the pulse-rate test was liable to fail just when it was most wanted. A child who did not seem frightened at the examination, whose fears were not quite conscious, might have flushed pallor, trembling, fever, and even growing pains, and might respond very badly to pulse-rate tests and yet never develop rheumatic disease. The pulse-rate might be lower in sleep, but some of these

children allowed themselves no quiet even in bed; they had nightmares and ran a rapid pulse all night.

Dr. ADOLPHE ABRAHAMS said that these tests did not test the heart qua heart and, in his experience, would break down in both directions. People who did badly at tests might be capable of considerable exertion, and vice versa. It was impossible to disregard the nervous factor. The problem of response to exercise was not merely one of the heart's efficiency, but was bound up with many other factors. These tests showed the efficiency of the individual for exercise, or perhaps just the tone of the vasomotor system. If tests could be devised to estimate the heart's efficiency they would be of great value.

Dr. MARGARET LOWENFELD described an attempt in Glasgow to estimate the efficiency of the heart in a large number of normal children of both sexes between the ages of 6 and 13. The work had been abandoned because of the extraordinary variety of results obtained. For instance, a perfectly healthy child of good heredity had given bad test results; it had subsequently been ascertained that she had that afternoon learned of her success in terminal examinations and the excitement had caused her heart to fail in the tests. A series of rheumatic children with definite cardiac affection had shown the converse; a child with considerable enlargement and a double mitral lesion had given a perfectly normal reaction after moderate exercise. Without a very careful examination into the neuro-physical character of the child illusory figures would be obtained from tests of this nature.

Dr. B. E. SCHLESINGER said that the physician of the convalescent home often had great difficulty in securing proper attention to the children after discharge if they could not be put under a supervisory centre. He thought that the American statistics were so elaborate and overwhelming that workers were likely to get lost in them. All kinds of factors entered into the pulse-rate, such as the time of day it was taken. As in "soldier's heart," recovery of rate and efficiency might occur with improvement in the general health. The problem was not so much one of testing cardiac efficiency as of recognising signs of rheumatic activity, and that would not be done by these tests. Much harm had been done by keeping children at rest for long periods unnecessarily. A point that might be of use was that the normal pulse-rate dropped 10 to 20 beats during sleep, while the night pulse-rate of the rheumatic child with active carditis approached that of the day.

Dr. T. W. PRESTON remarked that criticism of the paper seemed to be destructive rather than constructive. No one had suggested that a diagnosis could be made on this test, but in the majority of cases a heart that could pass it satisfactorily was a good heart. There might be exceptions, but as a rule the heart that was constantly rapid after exercise had something the matter with it. He would like to know how these "normal" children with hearts that failed to pass the test got on years afterwards; did they live to old age without any cardiac trouble? He had found these tests a very considerable help, and it would be unfortunate if the report went out that the meeting was unfavourable to them. The practitioner wanted to know how to keep a doubtful heart under observation, what he was to look for; a routine test of this kind would give him a great deal of assistance.

Dr. BERNARD MYERS asked whether the size of the collar round the arm made any difference to the blood-pressure readings and whether the instrument had been tested at Kew. Dr. Parsons Smith had been working at children's blood pressure and had found tremendous differences. The nervous child was a most important source of error. It was doubtful if any test would be of real solid value unless it could estimate the effective action of the pituitary.

Dr. E. A. COCKAYNE said he had tried some of these tests on soldiers and had been struck by the way in which patients with organic disease might pass them quite well, whereas many who had no enlargement and no organic disease did them very badly. So many rheumatic children had an unstable nervous system that these tests were merely picking them out from the remainder.

Dr. E. STOLKIND described his experience of these tests in a military heart hospital in London. In the majority of positive cases the only heart disease present was nervous.

Dr. F. S. SWINEY agreed that the tests were open to fallacy because the system tested was not only the circulatory but also the nervous and the respiratory, and indeed the whole organism, but thought nevertheless that at this stage it would be wrong not to give this promising method of investigation fair consideration and trial. It was important to remember that the closest coöperation must exist between the hospital giving treatment and the rheumatism supervisory centre, and that it was best to examine a few children thoroughly.

Flight-Commander E. D. DICKSON said that these tests, with others, were carried out on aviation candidates for the Royal Air Force, and that great importance was attached to them in passing men for flying.

Dr. HUGH STANNUS said that vasomotor instability was in itself a rheumatic manifestation. It would be very interesting if these children could be watched for a long period to prove whether or not they were rheumatic.

Dr. SLOT, in reply, emphasised that he had never intended the tests to be in themselves diagnostic: they were just one method to be used together with others. The child's parents could not be kept waiting indefinitely, and the doctor had to decide within a short time what kind of life the child was to lead. If he went wrong on these tests, at any rate he went wrong on the side of safety. The tests had been based on a large number of observations and the fallacies had not proved sufficient to warrant real mistrust of them.

Presentation of Cases.

Dr. W. G. WYLLIE presented two cases. The first was a boy of 8 who had fallen from a second storey window four years earlier. Six months after the accident obesity had set in and during the third year he had had frequent frontal headaches, nausea and sometimes vomiting. He was always thirsty but had no polyuria. There was generalised adiposity so that he weighed 81 lb. instead of the 54½ lb. normal for his age. His intelligence was unaffected and there were no abnormalities in the sexual or nervous systems.

The second child, a boy of 6, had fallen while racing upstairs, and in his case, as in the former, fracture of the base of the skull had been suspected at the time. A month or two later his appetite had increased enormously, but without thirst. He would gnaw bones if allowed. He passed 4–6 pints of urine daily, of low specific gravity, but without abnormal constituents. He had fairly frequent frontal headaches but no drowsiness or impairment of intelligence. His nervous system showed no anomalies and his weight and physical development were normal.

Dr. E. A. CROOK showed a case, with skiagrams, of abscess at the lower end of both tibiæ. For a time there had been no leucocytosis, but the temperature had not responded to salicylates. He had only seen one other equally symmetrical case—abscess of the second metatarsal shafts.

Dr. WINNICOTT said the child had first been brought to his clinic as a case of rheumatism, having been taken ill with swelling of the ankles and big-toe joints. When examined a week later his feet had been normal except for enlargement of the ends of the tibiæ.

The CHAIRMAN regarded this as one of those rare cases where the infective focus was really primarily epiphyseal. The difficulty of penetrating the cancellous tissue of the diaphysis had saved the child from a bilateral osteomyelitis.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society took place at the rooms of the Medical Society of London on Feb. 22nd, the chair being occupied by Dr. F. J. H. COUTTS, the President, when a discussion on the diagnosis and treatment of

NON-VENEREAL AFFECTIONS OF THE GENITALIA

was introduced by Dr. H. C. SEMON. He first acknowledged his indebtedness for much of his material to J. Callomon's useful book, and remarked that he would discuss only such conditions as were seen by the dermatologist, and of which he had had personal experience. A number of cutaneous diseases, though not venereal in the ordinary sense, could yet be contracted through sexual intercourse. He set out to deal with them under the following six headings: (1) genital manifestations of the more important dermatoses; (2) pruritus anogenitalis; (3) genital dermato-mycosis and the epizoötic infections; (4) herpes genitalis, molluscum contagiosum, condyloma acuminatum; (5) non-venereal ulcers of the genitalia; (6) certain lymphatic affections.

(1) The delicacy of the epidermis covering the genitalia and the specialised structure of the scrotal skin gave small cause for wonder that the genitals were a common site for many of the *dermatoses which affected the rest of the body*. Of these the commonest was eczema. If this resisted the simple hygienic measures of proper clothing and protection and the application of soothing remedies the thoughts should turn to such possible underlying causes as pediculi, oxyuris, glycosuria, dysentery. The initial pruritus due to pediculi often resulted in severe dermatitis following the use of too powerful parasiticide ointments. The pediculus was easily killed by one or two applications of benzol. In obstinate ano-genital eczema in children the threadworm should be sought, while in stout women the urine should be examined for sugar, and bacteriologically for the colon bacillus. Hæmorrhoids and fissure in ano must not be forgotten as possible causes. A form of chronic dry eczema which favoured the genito-crural region was that termed neurodermatitis chronica circumscripta. Its character was lichenoid, it itched intensely, while owing to the difficulty in securing sleep, it was sometimes the precursor of a serious nervous breakdown. Each type of predisposing cause must be treated in its own proper way. In cases in which the acute symptoms had subsided there was no better "desensitisor" than X rays, but only under expert guidance, as in this region X ray dermatitis was more serious than in any other part. Sometimes psoriasis might involve the scrotum and penis only. Suppuration was rare and itching either slight or entirely absent. It might involve the glans and internal aspects of the prepuce. He emphasised the point that because *B. coli* were plentiful in the urine, or streptococci, these organisms were not necessarily the cause of the disease. After soothing remedies such as resorcin had brought about deturgescence the most efficient treatment was small doses of X rays. Lichen planus also showed a pronounced tendency to affect the mucous membranes, and the genitals might be the selected site. In cases of doubt the buccal mucosa should be examined for the "china-white streaks." The penile lesions in this condition did not ulcerate. Ordinary urticaria did not affect the genitalia alone, but Quincke's œdema was prone to attack the scrotum or one labium majus. The swelling was painless, and the absence of febrile disturbance and glandular swelling should obviate any attempt at surgery. Dr. Semon recommended intravenous injections of afenil (Knoll). Genital eruptions due to taking medicines were not usually recognised as such. They might be scarlatiniform, or morbiliform, or purpuric. The halogen derivatives, quinine in pessaries, and mercury if the patient was sensitive, were occasionally causal. The same drug might show different manifestations in various patients. Two other conditions—namely, erythema exudativum multiforme and pemphigus vulgaris—fairly frequently showed their primary manifestations on the external genitalia. Their onset was insidious and a complaint of pain was not usual. The outlook in erythema multiforme was good when the cause—usually buccal or intestinal sepsis—had been dealt with. Both these diseases had to be diagnosed from impetigo. It was very important to avoid confusion with syphilitic ulceration and cancrum molle.

(2) *Ano-genital Pruritus.*—There were two main categories of sufferers from it: the well-nourished, opulent, middle-aged man of sedentary habits; and the nervous, highly strung woman of temperate habits. The degree of pruritus varied enormously, from slight tickling at odd moments to itching of such intensity and persistence as to lead sometimes to psychical disturbance, occasionally ending in suicide or insanity. There were cases in which the most careful investigation was fruitless, and even X rays or radium failed to give relief. Among the possible contributories to be thought of were blood-sugar abnormality, leukæmia, morphinism, the cocaine habit, digestive disorders, idiosyncrasies to drugs and foodstuffs. No case should be lightly dismissed as hysterical and turned over to the psycho-analyst or to the unqualified radiotherapeutist. There was no standard line of treatment of cases of pruritus; each case must be investigated on the lines indicated. Of those with negative findings a considerable proportion yielded to X ray and radium treatment, and in one case which did not respond to these relief followed the injection, under general anæsthesia, of absolute alcohol.

(3) *Mycotic infections* of the genital area were very common, and should receive primary consideration when an irritating eruption occurred in this region. A cure rapidly followed the use of mild parasiticide ointments. Relapse was common.

Of the *epizoötic infections*, which included pediculi and the acarus of scabies, the latter was chiefly important because it was sometimes possible to diagnose a general infection on the presence of a single acarine burrow on the foreskin.

(4) The presumed ultra-microscopic virus of *herpes genitalis* could certainly be transferred, in the first instance, by coitus. The lesions were small grouped vesicles which ruptured rapidly, leaving small superficial denudations of the delicate epithelium of the glans or the labia, in which secondary infections were apt to occur. It bore no relation to herpes zoster. The lesions of herpes genitalis needed protection with indifferent lotions, powders, and the like, but it seemed impossible at present to prevent recurrences.

Molluscum contagiosum in the genital area did not differ from that elsewhere, and the treatment was surgical. The disease was contagious, had a long latent period, and could be conveyed by towels. Dr. Semon had seen two widespread cases which were contracted in a Turkish bath. *Condyloma acuminatum* affected the mucous membrane in preference to the skin. Favourite sites were the coronal sulcus in the male, and in the female the introitus vaginæ and labia minora. The small vegetating fungoid growths might coalesce and form a pedunculated cauliflower-like mass, in which secondary infection was common. It was conveyed in sexual intercourse, but did not rank as a venereal disease. It was very important to differentiate the cauliflower stage of this condition from fungating malignant growths.

(5) In regard to *non-venereal ulcers* Callomon's classification was useful. The first group were ulcerations following mechanical, chemical, thermal, or electrical influences. It included the ulcers contracted in coitus, the application of caustics to avoid venereal infection, self-inflicted wounds, and occasional accidents after diathermy. An X ray ulcer might be present, and total excision offered the only hope of permanent relief. The second group were the acute infective conditions. The acute tuberculous ulcer

was rare on the genitals; it occurred in cases of genito-urinary infection with quantities of bacilli in the urine. An anal ulcer infected from bacilli-containing fæces might spread forward and involve the posterior vaginal wall. Gangrenous ulcers on the genitals had a complex bacteriology, and the urine should always be examined for sugar. More than once he had cleared up such cases with salvarsan, and subsequently noted in those patients a positive Wassermann.

Discussion.

Dr. H. M. HANSCHELL said that the practitioner in the tropics found that lesions about the genitalia were very numerous. The leishmania sore might make its first appearance on the penis; he had also seen ringworm emerging from the end of a very long prepuce in a negro. A condition which he regarded as a true venereal disease, in that it was acquired in the act of sexual union, was that commonly termed the climatic bubo. It was very rare in temperate regions. The lesions were usually in the sulcus, and if swabbed with a lotion or with spirit there was almost instant healing. No one had yet discovered an organism in affected glands which had been excised and examined. He considered there was a true herpes which occurred round the prepuce and on the glans, distinct from that acquired in sexual union. Soon after the war he saw, in England, a few cases of ulcerating granuloma of the pudenda. The men had acquired the condition during the war; one of the patients had been for 18 months under treatment for chronic intractable syphilis. Meantime the ulceration had spread in each of these men through the abdominal wall into the bladder. Death occurred from exhaustion. The condition had not been described as occurring under the age of puberty, supporting the view that it was a true venereal disease. It began with a hard papule which closely resembled a syphilitic chancre. Early diagnosis was important, as when the lesion was small it could easily be excised. Usually a rapid cure was brought about by intravenous injections of tartar emetic. Elephantiasis of the vulva and penis had been seen in this country also. Cases which arrived in England often went to a surgeon, who proceeded to excise the obvious gland; then he found many deep glands were involved, down to the iliac vessels. All were removed. In two years the patient had elephantiasis of one leg, scrotum, and penis. Climatic bubo had not yet been reported as occurring in the female. It seemed to be connected with the prepuce. It did not occur in people who practised circumcision before puberty.

Dr. T. ANWYL DAVIES spoke of a common form of vaginitis, known as trichomonas. The bacillus did not stain well, and so was not usually detected. He had also seen vaginitis and cervicitis due to scabies.

Dr. F. C. DOBLE said he had seen cases of lichen planus confined to the genitalia, no lesions being seen in the mouth or elsewhere. It was his view that nearly all diseases in the tropics seemed to attack the penis, even leprosy.

Dr. W. S. SHARPE thought that herpes genitalis owned a variety of causes. He had always held there was some local reaction in the cutaneous nerve, or a toxic condition which caused the herpes on the glans. Diphtheroid infections in girls just before puberty caused a vaginal discharge, but never vulvitis or skin condition surrounding the vulva. It could be diagnosed naked eye because the discharge had an opalescent appearance, and did not set up an inflammatory reaction. The vaginal secretion in these cases was always very acid.

Dr. MARGARET RORKE agreed that pruritus ani was one of the most tiresome conditions to treat. Often a small focus of trouble had been missed in the early examination of the case, and then gradually larger areas of skin became involved, and the ultimate cure was very difficult, sometimes only with the aid of X rays.

Dr. DOROTHY LOGAN spoke of a woman who had most intractable pruritus of vulva and anus for 18 months, who was shown to have anal gonorrhœa. There was marked erosion of the cervix and an irritating discharge from that. No gonococci were found, but she had no doubt about the diagnosis.

The PRESIDENT, reviewing the discussion, said he had been struck by the number of the conditions for which X rays seemed to be valuable. It was, however, a means which must be applied with care and by an expert.

Dr. HANSCHELL and Dr. SEMON replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

AT a meeting of this Section on Feb. 8th Sir WILLIAM WHEELER took the chair in the absence of the President, and a paper on

Rectal Narcosis with Avertin

was read by Mr. F. J. MORRIN, who said he had used avertin as an anæsthetic in 54 cases, the oldest patient being 69 and the youngest 3. Excluding four cases in children in which the avertin enema was not retained, anæsthesia was unsatisfactory in only one case, an alcoholic subject. It was light in eight cases—but this did not prevent completion of the operation—and was satisfactory from the operative standpoint in the remainder, though of varying depth. Two cases showed a marked fall of blood pressure, long post-operative sleep, and a weak and rapid pulse which was not restored to normal for four days—symptoms obviously due to overdosage. Thirty-six were cases of advanced carcinoma of the tongue and face, suffering from cachexia, and unsuitable for any other form of anæsthesia. These were cases of what was ordinarily called "inoperable carcinoma," and were treated by diathermic coagulation. Such coagulation of cancerous growths was done with a very powerful diathermy apparatus, and required very deep anæsthesia. The danger of ignition made ether objectionable. Avertin allowed access to the growth and free intraoral manipulation. Mr. Morrin was very favourably impressed with the efficacy of the new drug, and said it was the anæsthetic of choice in toxic goitre. A brief experience with avertin amylene hydrate led him to regard it as a more effective anæsthetic agent, giving better abdominal relaxation and more certain anæsthesia; it was associated with shallow respiration, and was less liable to be attended with a fall of blood pressure. No post-operative bronchitis or pneumonia was observed, despite the fact that many of these aged patients were operated upon for disease of the mouth and pharynx. Care was necessary in preparing the solution accurately, and the dose of 0·1 g. per kg. of body-weight should rarely be exceeded. When it was necessary to increase the dose cautious fractional administration was advisable. Overdosage might possibly occur where the body-weight was decreased by operative removal of a large amount of tissue—e.g., amputation of a limb—in a subject of poor vitality.

The CHAIRMAN remarked that with avertin the patient apparently passed into a somnolent state within ten minutes. This was very different to anæsthesia with oil-ether, the great difficulty about which was the varying time it took to act. An operation under oil-ether could not be timed within three-quarters of an hour, as some patients went under much quicker than others. There was apparently no antidote to avertin, and there was a greater fall in blood pressure than when oil-ether was used. The better administration of avertin was, he thought, a matter of experience. He was interested to note the absence of post-operative symptoms following its use, as after oil-ether patients were sometimes very sick and some developed bronchitis.

Dr. J. BECKETT said that he had always regarded oil-ether as a very satisfactory anæsthetic, and had not found that patients vomited much after it. There seemed to him to be a great deal of complicated technique in giving avertin. The oil-ether method was very simple.

Mr. W. DOOLIN offered his congratulations to Mr. Morrin on being the first surgeon outside Germany to have had an opportunity of testing the new drug. The intention of the German authorities that avertin should not be available for general use until it had been given an exhaustive trial in competent hands was praiseworthy. Opinions in Germany as to its use were very divided. Amongst those using the drug, its method of employment was twofold: it was used either as a basal narcotic, preceded by other narcotic drugs, and with additional ether administration, or else as the sole narcotic medium, and it was in the latter group that most accidents had occurred. To judge from published reports, the difficulties of administration were rather more serious than Mr. Morrin had stated; it has been repeatedly stated that even slight errors of technique might lead to serious effects in patients. The chief dangers were overdosage and overheating; the rapid fall of blood pressure had led to fatal secondary hæmorrhages in a few cases; fatal colonic necrosis had been reported as the result of overheating of the drug before injection. Many observers working with the drug had admitted that the chief disadvantage was the fact that it was impossible to "steer" the anæsthesia so produced. Some had considered that the dosage by body-weight was unsatisfactory; it was impossible to state at any time how much of the drug injected had been absorbed into circulation. Its advantages were enormous when the anæsthesia was successfully performed. The abolition of vomiting during and after operation was beneficial to the patient, particularly so in the case of children. Reports in German literature during the past two years showed a marked falling off of post-operative pulmonary complications. There seemed little doubt that, notwithstanding certain dangers alluded to, avertin was a great step forward in the technique of anæsthesia.

Dr. P. MACCARVILL, who had assisted Mr. Morrin when he started using avertin, said that a 3 per cent. solution had been used, but it had been found difficult to get the powder to dissolve, and later they had used a 2·8 per cent. solution. The fluid was heated first to 45° C., and cooled to 40°. The first time he had given avertin he had been rather alarmed, as the patient's blood pressure fell and the breathing became very shallow; but the operation was quite successful. Avertin seemed to him to some extent a phasic anæsthetic; at one time the patient appeared to be very deeply anæsthetised and at another not so deeply. When administered with care he regarded it as invaluable.

Mr. A. A. MCCONNELL said that so far nothing like an ideal anæsthetic was known, and a good many of the objections to avertin applied also to ether. He referred to the possibility of using diathermy in the mouth when rectal ether was being employed, and said that he had been doing this for years without encountering any difficulty.

Mr. MORRIN, in reply, said he had tried rectal oil-ether extensively, and thought that there was no comparison between the two anæsthetics. There were many dangers from oil-ether also. There was no great technical difficulty in preparing avertin. The mortality following its use had occurred in the early stages when too big doses were given, and when it was used in cases of hepatic and renal disease. Where the blood pressure fell very low he had found that ephedrine controlled the fall. He had never seen a case of secondary hæmorrhage after avertin anæsthesia.

Mr. R. A. STONEY read notes on a case of cholecystocho-duodenostomy, and a discussion followed.

Dr. HORACE LAW showed a steel pin which he had removed from the bronchus of a child of 7.

Reviews and Notices of Books.

CYTOARCHITECTONICS OF THE HUMAN CEREBRAL CORTEX.

By CONSTANTIN VON ECONOMO, Professor of Neurology and Psychiatry, University of Vienna. Translated by Dr. S. PARKER. London: Humphrey Milford, Oxford University Press. 1929. Pp. 186. 21*s*.

"The Cytoarchitectonics of the Human Cerebral Cortex" is a translation, not, as one would infer from its title, of Economo's monumental work, "Die Cytoarchitektonik der Hirnrinde," but of his smaller and later book, not specifically mentioned in any place in this volume, "Zellaufbau der Grosshirnrinde." This is not made clear on the title-page. The smaller book received immediate recognition at the time of its first publication in the German two years ago, and it has already been translated into several languages. The first translation, the French version by Dr. Ludo van Bogaert, set a very high standard. A master both of cerebral anatomy and of the art of lucid writing, Dr. van Bogaert reproduced every refinement of the meaning of the original, and rendered this intricate subject more easy to follow by the clarity of his expression and by the explanatory heading with which he preceded each section. The result is a book which may become a French medical classic. Nothing comparable can be said of the English version. In the first few chapters, which are the most difficult part of the book to understand, there are passages so obscure that we have been able to discover their meaning only by reference to the original. The later chapters, consisting of more straightforward descriptions, are less difficult to follow, but the translation will not completely satisfy those English readers who are not in a position to turn to the original work.

Prof. Economo undertook anew the work that had been done by Brodmann, Campbell, and others, examining in detail the cellular structure of every part of the cerebral cortex. The great value of his work, apart from confirmation of earlier findings, is that it brings into the mass of detail an orderliness which simplifies the whole subject. While the six fundamental layers can be recognised in the cortex of practically every part of the brain, they vary from place to place to such a degree that essential similarities may not be recognised; Economo shows that three characteristic formations—the frontal, parietal, and temporal types, with slight modifications within their respective areas—cover a large fraction of the brain surface; two other types, the one abounding particularly in granule cells, the other in pyramidal cells, compose the rest of the neo-pallium. In general, cortex of receptive function is "granulous," and cortex of effective function is "pyramidal" or "agranular." The rhinencephalon and its adjuncts have, as is to be expected from its development, a very different structure.

The study of structure is one of the methods by which we shall gradually enlarge our knowledge of the localisation and integration of function in the brain, and Economo's work is a great contribution to neuro-anatomy. In this volume there are numerous illustrations, most of which are photographs in which detail is essential, and they are all well reproduced. The text teems with technical terms and we have found no misprints.

PHYSICS FOR MEDICAL STUDENTS.

By SIDNEY RUSS, D.Sc., F.Inst.P., Joel Professor of Physics to the Middlesex Hospital Medical School; Physicist to the Middlesex Hospital; Fellow of University College; Fellow of the Royal Society of Medicine. Edinburgh: E. and S. Livingstone. 1928. Pp. 230. 10*s*. 6*d*.

THERE exist already a large number of elementary books, which set out to help the student through

his preliminary studies in physics. There is ample justification, however, for the production of another by an experienced teacher who is inspired with a desire to interest medical students in a subject which is becoming increasingly important as a grounding for the later subjects of their curriculum. Throughout this new text-book is a medical bias; without dragging in so-called "medical applications," Prof. Russ illustrates his topics in a natural way by means of examples drawn from medicine. The student, who is often disposed to regard his year of instruction on the basic sciences with impatience, will appreciate this method of helping him to grasp the bearings of physics on his chosen life-work.

An unusual feature is the policy of omitting examples other than those in the body of the text. Zealous students will refer to special books and to papers set in previous examinations to make up for this defect; the less enterprising ones may welcome the omission of exercises usually included at the end of each chapter in elementary text-books of physics, and decide that it is unnecessary to test their knowledge. However, since the majority of the readers of the book will be attending lectures and practical classes in physics, it can be assumed that a suitable selection of numerical and other problems will be supplied by their teachers.

The work is well produced, is attractively printed, and has a good supply of clearly drawn diagrams, which, with the exception perhaps of Figs. 71 and 73, greatly assist the author in his concise exposition. Figs. 71 and 73 show the passage of light through a prism, in which dispersion takes place at one surface only; and the emergent violet beams seem to have become divergent.

The student will welcome a book which does not assume that, at the moment, he desires to study physics far beyond the requirements of his syllabus. The teacher will appreciate the fact that though the work is concise, it is not a mere cram book. The chapter on radioactivity and X rays is notable as one of the best summaries of our present knowledge that we have seen; in itself it would justify publication of the book.

PHOTOGRAPHS OF THE FUNDUS OCULI.

A Photographic Study of Normal and Pathological Changes Seen with the Ophthalmoscope. By ARTHUR J. BEDELL, M.D., Member of the American Ophthalmological Society. Philadelphia: F. A. Davis Company; England: Stanley Phillips, Billericay, Essex. 1929. An atlas containing 95 plates, 324 single pictures, and 272 stereoscopic photographs. Pp. 317. £5 5*s*.

To most ophthalmologists the contents of this book will come as a revelation. Hitherto, in order to preserve an impression of a fundus, we have had to rely on hand drawings, in pencil or water colour, which involve technical skill and a fatiguing ordeal for the artist who has to display patience. It is true that the result is often excellent, but the necessary expense and trouble involved render it hopeless to expect that this method should be made applicable to a large number of cases. Moreover, some of these pictures succeed better in emphasising the points that the surgeon desires to have emphasised than in conveying a strictly true objective representation of the facts. In this volume, on the other hand, we have a vast number of actual photographs of fundi which show clearly and without the possibility of bias the appearances as revealed by the ophthalmoscope. There are only two drawbacks. These pictures, being photographs, are in black and white, the various shades of red, white, and yellow actually seen with the ophthalmoscope being represented merely by varying shades. The other drawback is an unavoidable reflex of the carbon source of light (the pictures are taken with the carbon-arc lamp) which appears in the centre of the plate—in these pictures generally between the disc and macula. This volume, the first of its kind in English, contains a selection from 4000 photographs made with the Nordenson camera of Zeiss. The author acknowledges his debt to previous workers in the same field, and especially to F. Dimmer and to J. W. Nordenson, of Stockholm, the latter of whom demonstrated the method at the International Congress of Ophthalmology held in Washington in 1922. The photographs show a big assortment of varieties of normal and diseased fundi, and since a large proportion of them are stereoscopic it is possible to obtain a sense of relief that makes them in this respect even superior to the view ordinarily obtained with the ophthalmoscope. There is a foreword of 33 pages which explains the principles on which the collection of photographs is arranged, and to each photograph is appended a brief note of the case from which it was taken and the chief points which it is designed to illustrate. In some cases there is more in the description than can easily be made out in the photograph.

The foreword has been compiled without sufficient care, since in several instances the references to particular figures in the text are wrong. The errors should be corrected in a second edition.

FROM CLOUD TO SUNSHINE.

By ALFRED S. GUBB, M.D. London: Baillière, Tindall, and Cox. 1928. Pp. 128. 3*s*. 6*d*.

Dr. Gubb's volume on Algiers and Algeria as a Winter Resort is now in the eleventh edition, which proves it to be a useful guide to the physician and also to a wider circle of readers. In addition to information about the climate and the facilities for travel and recreation, the historical, archæological, and geographical descriptions are of general interest. The book contains a useful map, and practically every page is illustrated.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE, January 1929. The fate of old employees is discussed by W. I. Clark, who investigated the conditions of workers aged 65 years and over and of pensioners connected with a large factory. He concludes that, while pensions are necessary, they are unsatisfactory, and that by means of medical supervision and careful placement older workers may be advantageously kept at work. He found that the physical condition of workers aged 65 years and over varied little from year to year. Work is always more pleasurable than a pension.—An effort is made by C. O. Sappington to evaluate physical defects found at medical examinations. He adopts a grading scheme for assigning a numerical value to physical defects. On this basis he found that those applying for industrial work had scores with a mode at 85, as compared with a mode of 95 for university men. This is supposed to demonstrate that physical and mental make-up are closely correlated.—The physiology of industrial fatigue is effectively portrayed by R. J. S. McDowall. The subject is shortly and clearly set out so that it may be easily grasped.—The longest and most important article in this number of the journal is contributed by H. W. Armit on the development of industrial hygiene in Australia. Some account is given of the growth of industry in that continent, and of the relation between trade-unions and health conditions. The Commonwealth itself has established a Division of Industrial Hygiene for assisting to solve problems which may arise in the various States. Some report is given of investigations already carried out by the staff relating to the occurrence of dust diseases and lead poisoning. Though employers are still slow to grasp the value of the new science of industrial hygiene, which creates a spirit of willingness in the workers, Australia has made a good start on a sure foundation.

THE LANCET.

LONDON: SATURDAY, MARCH 2, 1929.

THE PREVENTION OF INFLUENZA.

THE virus of influenza is usually, if not always, transmitted by the droplets that are sprayed into the air with every expiration of an infected person. Strict isolation should therefore be an effective means of preventing the spread of the disease, and it is well to consider how far it has proved useful. In 1918 an attempt was made to prevent infection getting into Australia from the many heavily infected ships lying in harbour there. Enforcement of strict quarantine regulations achieved this object for three months, and the measures taken were thought so satisfactory that when influenza did at last break out in the Commonwealth the suggestion was made in all seriousness that it was due to an endemic virus rather than to a breakdown of quarantine. S. MONCKTON COPEMAN has reported the case of a school near Cambridge which remained free from infection during the whole of the autumn term of 1918. This was attributed to the pupils being forbidden to enter the town, where influenza was prevalent, and when the embargo was removed in the following term three-quarters of them contracted influenza within a fortnight of infection being introduced. Many instances also have been reported in which individuals and families have eschewed all contact with the world outside their houses and have thus escaped attack. Such examples illustrate the conditions under which rigid isolation is likely to be successful, but they serve at the same time to emphasise its limitations in practice. Once an influenza epidemic has broken out, the isolation of all infectious cases from the rest of the population—in contradistinction to isolation of the fit from the infected—is impracticable if not impossible. There are instances, it is true, in which isolation of patients is said to have checked an epidemic; thus H. JENSEN, in 1918, on an island of 750 inhabitants, isolated the first (and only) 12 cases of an influenza outbreak and enforced the wearing of masks and overalls on all who attended them. But there is no evidence that in large communities the notification and isolation of patients has had any appreciable effect on the total incidence of influenza. In many epidemics a large proportion of cases, perhaps sometimes more than half, are so mild that the sufferers are able to continue their usual avocations. Again, although the causal organism of influenza has not been identified and therefore the existence of carriers is hypothetical, it is probable that healthy distributors of the virus play a part in spreading infection. For these reasons notification and isolation of cases, even if machinery were available, would be unlikely to affect the general morbidity appreciably. Under the rather exceptional conditions of ship life J. H. L. CUMPSTON found that taking the temperature of the whole ship's company daily, with prompt removal of all who felt ill or who had any fever, did not prevent attack rates ranging from 30 to 89 per cent. Even when allowance is made for the close contact of those on board ship, it is hardly conceivable, in face of the failure of this routine, that any measures for the discovery and segregation of infected individuals which could be enforced in a big city would do much to lessen the incidence of epidemic influenza.

The value of vaccine prophylaxis in influenza from the first seems very doubtful, for even an actual attack of the disease apparently confers only a feeble and fleeting immunity. Admittedly the statisticians responsible for the Ministry of Health report on the 1918 pandemic came to the conclusion that "a naturally acquired immunity is often a valuable safeguard," but they could find no significant statistical evidence that the vaccines in use before the time of writing (1920) were in any way protective. Grave difficulties stand in the way of collecting reliable data on the efficacy of such prophylaxis, and even were it possible to prove that at a certain time and place one antigen was useful, there is no knowing whether it would be a success in the next epidemic or the next town. Owing to the extraordinary variability of the clinical picture and morbidity of influenza at different times and places, one must look with suspicion on the claims of those who hold that a vaccine has proved itself effective because it seems to have modified the severity of an attack. It is natural that clinicians with the acute pulmonary infections of 1918–19 still in mind should be inclined to attribute the mildness of their cases nowadays to better treatment or to prophylactic inoculation. The *post hoc ergo propter hoc* argument dies hard in medicine, and a good instance of its fallaciousness given by E. D. JORDAN relates to this very disease. In a group of 234 men, 101 got influenza within a few days, and it was at once decided to inoculate the remainder. For some reason this was not done; yet only one further case developed. If the vaccine had been used it would have been only too easy to convince the majority of medical men that the course of the epidemic had been, to some extent at any rate, influenced by active immunisation. In considering this difficult subject we must remember, too, that if inoculation is followed by an increase in morbidity it does not necessarily mean that the antigen is useless, for the incidence of the disease might have been still greater if it had not been employed. Even should vaccines do nothing to prevent attacks, they may sometimes limit the duration, severity, and complications of the disease, and hence it is reasonable that people should be given the chance of taking or refusing prophylactic inoculation after they have been warned that nothing is known for certain about its efficacy. The absence of any consensus of opinion on the value of vaccines prevents the profession from commending inoculation to the general public, but an efficient prophylactic would be such a boon, especially in schools and the public services, that every effort should be made in suitable places to continue the administration of influenza and catarrh vaccines under controlled conditions which will make it possible to judge their value fairly.

The question whether schools and places of entertainment should be closed during an epidemic is also unsettled. Influenza is so infectious that closure of day schools possibly has little effect on its incidence, since the disease is likely to be contracted by children

playing together in the streets or in their homes. On the other hand, where pupils sleep together in dormitories there is sometimes a very high attack rate and a serious type of case; and this makes it seem inadvisable for residential schools to reassemble, if an influenza epidemic has broken out during the holidays, until infection has subsided. Should such an epidemic manifest itself in term time, it may be possible, as COPEMAN'S report suggests, to prevent access of the virus to the school; but if quarantine should break down it appears unwise to spread the local strain of influenza abroad by disbanding the children to their homes. To close places of amusement is a theoretically sound policy, but probably has little effect on total incidence; it is, therefore, as a rule, uncalled for save in malignant epidemics which are so serious that the public will cheerfully accept restrictions of this kind. The general use of masks has been tried in America but was not a success; their inconvenience and disfigurement outweighed any obvious advantage. For all that, an efficient mask intelligently used is an excellent defence against droplet infection, and eight layers of surgical gauze will hold up all infective material. They have an undoubted value for those who have to attend or visit patients with serious and complicated influenza, but they must be used sensibly and must be frequently sterilised, for if their outer surface gets contaminated and they are put on back to front they become a danger rather than a safeguard. A German writer has lately advised plugging the nostrils with wool, but this would rather increase than diminish the risk of infection, for it would encourage mouth-breathing and thus lower the vitality of the nasal mucosa. Most authorities agree that wholesale administration of drugs such as quinine, iodine, and mercurials cannot do any good, even if it does no actual harm, and there is a growing disposition to include gargles and nasal douches in the same category. Failing any such measures of proved practical utility, the central health authorities have had to fall back on asking the public to obey the ordinary rules of personal hygiene, hoping that by this means individuals will to some extent be able to protect themselves. Though most people who have to work cannot avoid crowds and shun the company of all who have coughs and colds, they can usually diminish the number of such contacts; they can refuse to go to places of amusement and to fulfil social engagements, and they can avoid paying unnecessary visits to sick friends. Over-fatigue and malnutrition almost certainly predispose to infection. It is true that R. A. SPAETH found that exhausted rats, provided they were allowed to feed, were no more susceptible to inoculated infection than controls, but A. E. BOYCOTT and C. PRICE-JONES, while confirming SPAETH'S observations, showed that if the infective material was administered in the food instead of hypodermically, the fatigued rats died where the controls survived, which is more in harmony with clinical experience. Despite the fact that epidemic influenza occurs as readily in the tropics as in cold climates, all practical experience points to the danger of chill and undue exposure to cold, especially in association with exhaustion. To avoid these—though not at the expense of ventilation—is therefore sound policy, and will do something to prevent dangerous pulmonary complications.

There is little reason to suppose that any practical measures have much effect on the total morbidity of an influenza epidemic; avoidance of close and frequent contact with infectious foci probably tends rather to prolong the outbreak than appreciably to diminish the total number of persons attacked. Bu even in the most crowded institutions the attac rate rarely approaches 100 per cent., and some peopl manage to avoid all symptoms, although constantly exposed to infection. This observation suggests tha escape from the disease is seldom due to escaping al contact with infection, and we are obliged to believ that those who pass through epidemics unscathe do so because they have acquired some degree o immunity. Such reasoning leads to the fatalisti conclusion that a person must either be immune t the local virus or ultimately succumb to influenza and on this it may be argued that it is useless to tak precautions, so why not seek infection and get i over? The reports of COPEMAN and CUMPSTON already quoted, somewhat favour such an attitude for in both cases a community was submitted to muc inconvenience and escaped for a time, only to suffe in the long run like everyone else. Indeed, if it wer certain that the size of the infecting dose of virus or the period over which it is given, made no differenc to the result, and if we were sure that escape from a attack, or the type of illness, was only determined b the innate resistance of the individual, then the advic not to trouble about avoiding infection might b sound; if all epidemics of influenza behaved like th pandemic of 1918 the immunity conferred by an earl attack, even if only slight and transitory, might giv protection against the severe pulmonary infections t be expected in the later epidemic waves. But we hav good reason to believe that catching the disease, an its severity when caught, depend to some extent o the dose of infective material. Therefore if peopl take all the precautions to avoid infection that ar consistent with their mode of life, although they ma not succeed in escaping an attack of influenza, thei illness will probably be milder. Moreover, if there i any truth in the theory that a temporary immunit can be acquired by the inhalation of subinfectiv doses of the virus, it is conceivable that those wh take as much care as they can to avoid infection an keep themselves fit will gain an amount of immunit which, even if it does not carry them through th epidemic, will moderate the intensity of thei symptoms if they finally succumb.

Influenza is usually a trivial disease, and only minority of patients suffer from dangerous pulmonar complications or have a really severe illness wit unpleasant sequelæ. But owing to the high gener attack rate and the clinical characters of speci outbreaks, such serious cases may at any tim become numerous. Whilst it may be impossible t do much to lower the total incidence, conformance t the common-sense rules of health and behaviour lai down by the Ministry of Health may well do somethin to reduce the severity and mortality of the diseas by preventing massive doses of infection and by keepin the body in a fit state for combating infection once is established. In conclusion, we may say that th victim of influenza who does not go straight to be is both fool and knave. He is a knave because h goes on spreading infection among his associate and a fool because he is risking a long illness with i resultant loss of time and money, or even deat instead of submitting to a day or two's discomfort i bed. Everyone who had any clinical experience o the 1918 influenza must have seen many tragedie in which a strong man, from a mistaken sense of dut kept going at his work in spite of fever, only collapse later and die of broncho-pneumonia within few days. Fortunately, the present epidemic is le virulent, but the lesson is still applicable and i wisdom is proved by error every day.

WASSERMANN v. VERNES TEST.

THE Wassermann reaction is constantly being quoted in controversies as to the application of scientific discoveries to medical practice, and may be used with deadly effect by either side. For while it is common knowledge that the theoretical ladder on which the test rose to fame has long been discarded as unsound, the practical utility of the reaction to determine whether a patient has had syphilis in an active or latent form is unquestioned. In fact those who habitually work with this test in a laboratory are often dismayed at the unbounded confidence placed in their findings, since the test is complex and difficult to carry out and its reliability depends on other factors besides the experience and judgment of the pathologist. Even when the test is made in laboratories where routine procedures are most carefully standardised under the direct personal supervision of an expert, the reaction given by a patient not actually undergoing treatment may vary in an unaccountable manner; one week the reaction may be a strong positive, and the next it may be found weakly positive, or perhaps even negative. This may, of course, be due to alternations of the reaction in the patient himself, but other explanations may be given, as has been brought out recently by JOHN A. KOLMER.[1] He mentions, for example, that the composition of the distilled water used may effect the test; traces of magnesium salts are necessary for the reaction, and in certain localities it may even be desirable to use sterilised tap water in preference to distilled water. So apparently trivial a matter as the addition of amboceptor and corpuscles separately, or simultaneously in the form of sensitised corpuscles, also makes a difference. Dr. F. GRIFFITH and Dr. W. M. SCOTT showed in 1920[2] that there is no constant relation between hæmolytic activity and fixability, and, moreover, that the behaviour of a complement towards antigen alone is no indication of what will happen when it is brought into contact with the serum-antigen complex. Further experience in the technique of this test has not disposed of these uncertain factors. Moreover, much discussion has raged over the properties of different antigens. Some workers prefer plain extracts, others fortify these with cholesterin, others again remove the acetone-soluble fraction of plain extracts, and yet others use only the acetone-soluble fraction. Two years ago a series of comparative tests were performed by pathologists working in different laboratories, all of whom used substantially the same technique. The results differed by as much as per cent.

The inference from all available evidence is that the Wassermann test is so complicated as to require the undivided attention of a specialist who must carefully watch each phase of the control standardisation of the ingredients and each stage of the test. This work is almost too tedious to be expected from a hospital pathologist who has any other duties to perform. It is clear that if a simpler method than the Wassermann reaction could be evolved which was less reliable, it would be a boon to laboratory workers. The flocculation tests, which require fewer reagents, are still on trial. The latest of these to attract attention is the Vernes test, of which Dr. ANSEY BAYLY gives an account on p. 434 of our present issue. In this test the readings are made quantitatively, with an optical instrument of considerable delicacy. At the Technical Conference on Serum Tests for Syphilis, held at Copenhagen in May, 1928, under the auspices of the Health Committee of the League of Nations, where reports on the merits of the different tests employed were considered, the Vernes test was included for the first time in formal international discussion. The report of the proceedings of this conference is likely to be published shortly, and the verdict on the Vernes test will be awaited with interest. One advantage of this test is its long range of possible readings which, if they could be correlated with the clinical condition of the patient, would give a delicate estimate of progress. It is true that the exact relation of the degree of strength of the Wassermann positive readings to the severity of infection is unknown. But in practice a strongly positive reaction is regarded as an indication that the patient is not reacting to treatment, and the aim of the doctor in charge of the case is not only to ameliorate the patient's clinical condition, but also to render the Wassermann reaction permanently negative. The longer range on the Vernes scale might make it easier to correlate clinical condition with laboratory findings. The Vernes apparatus is now in use in France, Spain, Italy, Belgium, U.S.A., and South America. In this country it is being tried out at St. Mary's Hospital, at the Hospital for Sick Children, Great Ormond-street, and at St. John's Hospital, Lewisham, as well as by individual pathologists in their own laboratories. The fact that the antigen is issued from a central source reduces the number of variables to be contended with, and will facilitate the comparative investigation of the test. It is not necessary to prove that this test is more delicate than the Wassermann reaction to secure its widespread use. If it turns out to be no less sensitive and trustworthy it will be adopted with enthusiasm.

THE TENURE OF POSTS UNDER LOCAL AUTHORITIES.

Do the medical officers of health of urban district councils realise that they can be dismissed at a moment's notice? This startling position is established by the decision of Mr. Justice McCardie in Brown v. Dagenham U.D.C., a case of which the hearing began on Jan. 23rd and in which judgment was not given till Feb. 22nd. Mr. W. H. Brown held the posts of superintendent-assistant overseer and clerk to the council. He claimed damages for alleged wrongful dismissal, complaining that he had been the victim of a conspiracy by certain Socialist members of the council who could not forgive him because he had stood for law and order during the General Strike in 1926. The council's defence was that Mr. Brown had resigned from the clerkship and had been dismissed from the assistant overseership for neglect of duty and inefficiency. The judge found that Mr. Brown did not resign from his clerkship, but that the defendant council had a right to dismiss him at will from both posts.

On the case first coming on, the judge tried to induce the parties to settle the matter; when it nevertheless proceeded, and defendant's counsel argued that the local authority had power to revoke any appointment without notice, the judge observed that, if this were correct, "every town clerk, however eminent, every medical officer of health, however distinguished, and every treasurer could be ignominiously dismissed to-morrow without notice." The judgment has now confirmed the correctness of this

contention. What made Mr. Brown's case particularly hard was that he held his appointment under a minute of the defendant council stating that it was "subject to three months' notice on either side." There was no written contract otherwise between the parties, but a local government official would hardly expect a local authority to repudiate its own minute. Mr. Justice McCardie's decision means that the minute was ultra vires and worthless. Section 189 of the Public Health Act, 1875 (under which Mr. Brown was appointed as clerk) says: "Every such officer and servant appointed under this Act shall be removable by the urban authority *at their pleasure.*" This gives the local authority a power of dismissal similar to that possessed by the Crown, a power which cannot be negatived or impaired by any contract of service. Mr. Brown's appointment as assistant overseer rested on Section 5 (1) of the Local Government Act of 1894; this enactment does not contain the despotic phrase "at their pleasure," but the power of revoking an appointment is in the widest terms. The judge has held that an appointment under the 1894 Act can be as summarily terminated as one under the 1875 Act; Mr. Brown could be dismissed at any time without cause given and without notice. The result was that his claim for wrongful dismissal failed.

The questions of fact—whether he resigned or was dismissed, and whether he was guilty of misconduct or not—were heavily disputed. At various points the judge seems to have taken the view that Mr. Brown was right and the council wrong. After the date of the purported resignation the council gave him three weeks' leave, but omitted to pay him the three weeks' salary. This latter sum he has been awarded by the court; it had been paid into court with a denial of liability; the judge says it would have been more proper and generous if there had been an admission of liability. Mr. Justice McCardie has further stated that Mr. Brown's dismissal was not only harsh but also unjustifiable, and that the charge of misconduct was "very unfortunate both in its wording and its object." The judge, however, could not say that the council had acted dishonestly nor did he find himself entitled to substitute his own opinion for the council's almost unanimous view. In making these criticisms he went perhaps somewhat out of his way, since his decision that the council possessed an arbitrary power of summary dismissal was the turning-point in the case. The criticisms are noteworthy as a reminder that the officer of a local authority cannot always rely upon fair and generous treatment, but may find himself exposed to unexpected antagonisms when the political atmosphere is heated. The judge's order that both sides should pay their own costs doubtless marks his view of the merits and equities of the successful defence. Meanwhile medical officers of health, who are in exactly the same precarious position as Mr. Brown, can hardly be content with their defencelessness. The critical words "at their pleasure" in Section 189 of the 1875 Act seem, by virtue of Section 190, to be applicable to the medical officers of health of rural as well as urban authorities. The position of county medical officers of health is different, since by Section 68 of the Housing, Town Planning, &c., Act, 1909, county councils can remove them only with the consent of the Minister of Health and not otherwise. In a county borough, where any portion of the salary of the medical officer was paid out of moneys voted by Parliament before it was constituted a county borough, the whole-time medical officer has a safeguard under Section 1 of the Public Health (Officers) Act, 1921. He is removable by the authority only with the consent of the Minister, or else by the Minister himself, and not otherwise. If the legal decision in Brown *v.* Dagenham U.D.C. stands, the insecurity of non-county medical officers will certainly be for Parliament to rectify. Is any step being taken in the Local Government Bill to secure the tenure of all medical officers in terms which are clear and universal?

Annotations.

"Ne quid nimis."

THE ROYAL SOCIETY.

THE Council of the Royal Society, at a meeting on Thursday, Feb. 21st, recommended 15 candidates for election into the Society, among whom several have done work directly or indirectly connected with medicine. The election of Dr. Frederick William Twort, superintendent of the Brown Animal Institution, will be regarded widely as a fitting recognition of his long career of research in the course of which his name has been identified, but not over generously, with a pathological discovery of high importance. Dr. John Mellanby, professor of physiology in the University of London, is known for his studies on digestive enzymes and hormones. Dr. Henry Stanley Raper, professor of physiology in the University of Manchester and director of the Physiological Laboratories, has to his credit a quarter of a century's successful labour in the laboratory and as teacher at universities in this country and in Canada. Other new Fellows who have contributed to the advance of medicine are Dr. James Gray, a Fellow of King's College, Cambridge, and lecturer in comparative anatomy in that University; Prof. Harold Roper Robinson, professor of physics in the University of Wales; Mr. Charles Drummond Ellis, University lecturer in physics at the University of Cambridge; Prof. A. J. Allmand, professor of physical and inorganic chemistry at King's College, London; and Prof. A. H. R. Buller, professor of botany in the University of Manitoba.

REFLEX MUSCLE ATROPHY.

THE cause of the muscular wasting associated with arthritis has been much discussed, but the various theories propounded to explain it cannot be said to have a firm basis in physiology or pathology. We publish in this issue the report of an investigation by Dr. Beryl Harding which seems to be a substantial contribution to the solution of the problem. In a previous communication she described an important difference between the metabolic activity of muscle which had wasted as a result of arthritis and that of those in which the wasting was secondary to disuse. The former were found to show a great increase in oxygen consumption, which was almost double that of the latter and of normal muscles. This led to the hypothesis that the affected muscles might be in a state of reflex stimulation produced by impulses arising in the painful joints, and Dr. Harding's latest investigation has confirmed this explanation. Her physiological research throws light upon certain clinical facts concerning this type of muscular wasting. For example, it is a familiar observation that the tendon reflexes are increased in muscles whose wasting is attributable to arthritis; and this is clinical indication of reflex hypertonia. R. K. Lippman and S. Selig,[1] whose experimental study of muscle atrophy Dr. Harding quotes in her paper, object to her explanation of the increased oxygen consumption of the wasted muscles, on the ground that such heightened metabolism may occur in any spastic muscle, regardless of its diminution in size. But it is a well-known physiological fact that the metabolism of the spastic muscles of decerebrate rigidity is greatly below that of normal muscles. Clearly the reflex activity of the wasted muscles in arthritis is extremely expensive of energy and is physiologically different from the reflex postural hypertonia which results when certain levels of the nervous system escape from higher control. Clinical observation suggests that reflex muscle wasting is a concomitant also of lesions other than arthritis. It is to be found, for example, in association with metastatic neoplasms

[1] Surg., Gynecol., and Obst., 1928, xlvii., 512.

one. The most familiar manifestation of such asting, however, is as the product of chronic pul-ionary disease, especially tuberculosis. Unilateral asting of the pectorals, trapezius, supraspinatus, homboids, levator anguli scapulæ, and even of the ongue is almost constantly to be found in the resence of tuberculosis of the upper lobe. This asting, like that due to arthritis, is associated, at ast in the early stages, with heightened reflex ctivity, manifested as myotatic irritability. It is herefore probable that arthritic muscular atrophy is special instance of a general tendency to the ccurrence of heightened reflex muscular activity in he neighbourhood of a visceral lesion. Such a eflex may well be protective in purpose, if we may peak teleologically, but its production by pulmonary isease which is often painless indicates that it is not xclusively associated with lesions causing pain.

PARASITE v. HOST.

In the interplay between an animal or plant and s parasites there is always a tendency for selection o produce a race of hosts which can more or less uccessfully resist the parasite and a race of parasites hich can effectively evade the host's defence. As the ost population becomes more immune so the parasite opulation is apt to become more virulent. A articularly clear example of this adaptation in a arasite has lately been published [1] by Mr. W. A. R. illon Weston from the School of Agriculture at ambridge. The Sherman variety of wheat is highly sistant to the fungus (*Tilletia caries*) known as bunt"; thoroughly contaminated with bunt from ittle Joss wheat, which is susceptible, it produces crop with 1 or 2 per cent. of diseased ears. If this herman bunt is used to contaminate Sherman seed the next crop the rate of infection rises to 86 per ent. Another resistant variety, Berkeley Rock, was ontaminated in 1927 with Little Joss bunt and roduced 1·6 per cent. of bunted ears; in 1928 ontaminated with its own bunt this was increased to 1·1 per cent. The discovery or production of immune arieties has protected many crop plants from estructive diseases, but the parasites are evidently ying all the while to circumvent the plant breeder. he villainous mycologist evidently has a weapon ore effective than tares.

LEUCOCYTIC CHANGES DURING LIVER THERAPY.

The effects of the Minot-Murphy method of treating ernicious anæmia on the red blood cells, the hæmo-obin-index, and the blood nitrogen have been udied by various observers, but with the exception L. E. H. Whitby,[2] no one seems to have made a rticular study of the changes in the white blood rpuscles. Dr. G. Giauni, of the University of noa, has lately published some observations [3] ich fill this gap in our knowledge. He found that e leucopenia invariably present in pernicious anæmia uld be divided into three groups: (*a*) Cases with ense medullary reaction, representing about per cent. They are characterised by a marked cocytosis produced by the liver treatment and ri passu with this increase in the white cells there an increase in the red cells. Poulton and Langmead ve described a colour-index above normal. (*b*) ses with adequate medullary reaction, comprising out 55 per cent. in which the number of leucocytes urn to the normal amount; in some cases the mber of the cells may be slightly below normal, others slightly surpassed, but not to the same ent as in the first group. (*c*) Unfavourable cases h slight or absent medullary reaction. In about per cent. of the cases there is little or no response a prolonged ingestion of liver, the red cell increase is very small, and pari passu the number of white cells undergoes a very slight increase; the leucopenia remains and is of unfavourable prognosis. As regards qualitative changes, the hepatic treatment influences the behaviour of the neutrophiles. In the majority of cases (75 per cent.) the polymorphs increase in number without going beyond the normal. The increase in granulocytes corresponds to the total increase in leucocytes. In rare cases after treatment no variations are observed; the total mass of leucocytes increases very little and usually only reaches a figure below normal. There are still rarer cases where the number of neutrophiles is at the end of treatment below what it was at the beginning. As regards eosinophilia, which has been noted by Whitby, Dr. Giauni met with only one instance of slight increase (3 per cent.) in all his cases. The increase in polynuclears, whether they be neutrophiles, basophiles, or eosinophiles, seems to indicate that the erythropoietic activity of the bone-marrow is at the time actually increased, even though there are marked qualitative changes in the leucocytic formula. There was no change of any importance noticed in the basophiles nor in the monocytes. In pernicious anæmia there is a relative lymphocytosis, and this is only natural since, according to Ceconi, the lymphatic tissue continues to function normally, and given this relative lymphocytosis it is natural that with the increase of granular neutrophiles the number of lymphocytes should diminish. Generally the reduction in the number of lymphocytes is directly proportional to the increase in neutrophiles; the more the former increase the more the latter diminish. Assuming, in the absence of evidence to the contrary, that in pernicious anæmia the lymphatic system functions normally, it may be concluded that the behaviour of the lymphocytes is directly dependent upon the behaviour of the polymorphs, whether they be neutrophiles or eosinophiles, and that these reflect the greater or lesser activity of the bone-marrow.

A PIONEER IN SEXUAL PSYCHOLOGY.

It is a truism that the moral and intellectual outlook of mankind varies with time and place, but only occasionally does some event draw our attention to changes that, without notable landmark, have occurred within our own days. Such an event is the publication of a biography of Havelock Ellis, by Houston Peterson.[1] The young Havelock Ellis is pictured as a studious, introverted, and conscientious youth, whose inner difficulties were greater than those of a similarly constituted youth of to-day, for the mystery of sex was then so well guarded that, as the biographer points out, Huxley's "Textbook of Physiology" went through many editions without a chapter on reproduction. These difficulties prompted in him the resolve to explore the dangerous ocean of sex in order to save other young people from the perplexities that tormented him, a resolve which led to wider efforts and the collection of a vast amount of information upon sex life, normal and abnormal. The middle-aged amongst us may remember that 30 years ago the first of his Studies in the Psychology of Sex became the subject of criminal proceedings, and was roundly condemned as lewd and obscene. In recent years frequent public references to Havelock Ellis and his work give no hint of this stormy reception, though the series has never been published in England, and the last volume, entitled Eonism and other Studies, which was published in America last year, contains in its preface a suggestion that certain material has been omitted on account of English prejudices. In the intervening years a change of attitude has certainly taken place; venereal disease and birth control may now be publicly discussed; many young people of to-day accept as ordinary knowledge information upon sex topics that in the last century would have been forbidden to them,

[1] Havelock Ellis. London: George Allen and Unwin. Pp. 432. 18s.

and would smile in wondering derision if told of the elaborate precautions that were taken, only a generation ago, to separate the sexes when bathing. In the scientific world, though there is not yet full recognition that science must know no prejudices, yet we no longer make the pretence that difficulties and abnormalities of the sexual life can be made non-existent by ignoring them. Hence the work of Havelock Ellis can now be viewed more dispassionately, and no one can read this biography without recognising that he was far from the monster of iniquity he was once considered to be. Few of us, it may be admitted, can free ourselves as he did from the last trace of emotional reaction against subjects that the most enlightened have at some time or other regarded as repulsive, and yet only such freedom enabled him to obtain the material he has given to the scientific world, for the emotional reaction often appears as moral judgment and effectively prevents a sufferer from voicing his difficulties or even revealing their existence. The value of his clinical material may diminish as the growth of knowledge makes it commonplace, but the change in the spirit of medical science towards the problems he made his own may perhaps be the most enduring result of his labours.

THE SALVAGE OF SLAUGHTER-HOUSE AND MARKET REFUSE.

THE care and thought a city corporation to-day devotes to the utilisation of waste is well brought out in a paper on the Treatment of Organic Waste, by Mr. W. Weaver, chief chemist to the Birmingham Corporation Salvage Department, which appears in the *Journal of the Royal Sanitary Institute* for February. His plant handles, he tells us, 4000 tons of refuse in the year, in the midst of a densely populated area, without smell or nuisance, and turns out 1000 tons of feeding meals and fertilisers, and nearly 100 tons of fat. The refuse is animal or vegetable. Animal refuse is tipped out in a room with thorough exhaust ventilation into the hot flues of the destructor, and the floor is washed down and disinfected daily. Meat goes into one of the "melters," steam-jacketed at 40 lb. pressure. As the temperature of the new charge rises, steam comes off and is removed by a vacuum pump, and at last the protein material is dry and swimming in melted fat. This free fat is run off; what is left is put into heated centrifugal extractors, where any remaining fat is squeezed out, and the residue is ground into feeding meal. The total fat is collected, washed, dried, and sold for making soap or candles, its price being all the higher because it is prepared at a relatively low temperature under this vacuum treatment. Other protein "meal" is got from "slime" and "offal." Slime used to be known as gut-scrapings. It contains 90 per cent. of water, so it will not pay for drying, but the albumin is coagulated by boiling, and is then collected, dried, and ground up. The offal—stomachs of slaughtered animals, their intestines, and the contents—is in part made into fertiliser; the rest is minced, washed clean of the "contents," freed from fat, if any, and ground into a feeding meal. Bones from dustbins have a fatty film over them that attracts dirt, so they must first be washed in water at 50° C., then they are heated rapidly to get quick protein coagulation, the fat is extracted, and the remainder is ground to bone meal, a valuable fertiliser. Fish residues can be made into a good feeding meal once the valuable fish oil, which spoils the meal, has been removed. The oil from herrings or mackerel is useful in currying leather, in making linoleum, and for other purposes. All these processes are carried out separately, different melters being employed for feeding meals, for meat, for fish, and so on. In dealing with vegetable refuse, the great source of difficulty is water, generally 90 per cent. by weight. Gross forms of contamination such as metal, wood, stones, and glass, are mechanically removed, and the vegetable matter is then passed through rollers which squeeze out the water, the resultant ribbon being dried by the flue gases. So much of it is indigestible—a great deal is cork dust and grape packing—that it can only be made into fertiliser; yet it has value, taking the place of stable manure, which is now not so easily obtainable as it was.

PUBLIC HEALTH NURSES IN SCOTLAND.

A SCOTTISH education authority is inviting applications from trained nurses for appointment as nurses in the county schools. Over and above general training in nursing the qualification of the applicants is to include experience in diseases of the ear, nose and throat, eye and skin, and some training in children's diseases, as well as in a fever hospital, and preference will be given to those with school or public health experience. A salary of £120 is offered, rising by increments of £10 to £210 per annum, with an allowance of £13 for subsistence and £10 for uniform. It is instructive to note how these requirements cut across the present-day equipment of the average nurse. When the General Nursing Council was established it was realised how imperfect was the so-called general training of nurses for public health work. Nurses with four years' hospital training may have a high standard of medical and surgical experience, and yet be unqualified to deal with much that lies outside hospital practice. The general hospital trainee usually is unfamiliar with fevers, and yet fevers are certain to be among the work that falls to the school or district nurse. It is unfortunate that, owing to the splitting up of the Register, the nurse who has trained in the wide range of work required by the health authorities has been relegated to a subordinate section of the Register. While no doubt this will rectify itself in course of time, there is little doubt that as public health work develops under the new system of local government the nurse with "general training" only will not be in the running with the nurse who is trained in the institutions of the local authorities themselves. When the work of the poor-law and of the education authority is transferred to the new health authority, it will be open to the larger municipalities to train nurses in their own institutions, providing them with facilities for practice in all branches of public health and school work. It may then be regretted that the classification for registration purposes was not conceived on a broader basis, for in Scotland at least registration has suffered because public health nurses have not found it of much value. The advertisement to which we have referred is a good illustration of the reasons why. With the resources of the poor-law hospitals, the fever hospitals, the maternity hospitals, and the child welfare centres, as well as the school clinics, the new authorities will be in an exceptional position to provide a worthy training curriculum. In the Aberdeen scheme the nurses will have the advantage of training in more than one institution under the same authority. When the new system becomes general the same will be true all over Scotland.

STERILISATION OF THE FEEBLE-MINDED.

ALTHOUGH our institutions are crowded with the feeble-minded, and even the system of boarding suitable cases with families is reaching its limit, public opinion in this country has so far refused to give serious consideration to the rights and wrongs of sterilisation. Possibly the memoranda lately issued by the Eugenics Society and other bodies will awaken interest in the subject, and this is a fitting time to point out that there is no foundation for the widespread belief that sterilisation means unsexing—a belief on which a good deal of ill-informed opposition is founded. It is now 20 years since public opinion in California was convinced of the desirability of sterilising mental or defective patients who are stable to support themselves or whose families are able to care for them, and since that time 5820 California

citizens have been sterilised. Of the 3232 men so treated 2705 were insane, and 527 feeble-minded; of the 2588 women 1792 were insane and 527 feeble-minded. The procedure in use is described by Dr. R. L. Dickinson in the *Journal of the American Medical Association* of Feb. 2nd. After a patient has been studied in the State Hospital, his case is taken up by a full staff at a regular weekly or bi-weekly meeting, when the family record, the judge's report with its opinion from two physicians, and the new hospital history, are read in detail by the physician in charge, together with the results of the physical, mental, and laboratory examination. The patient then appears and is questioned by several of the six to ten persons present. Should the opinion be reached that he is a suitable subject for sterilisation, this is carried out by the surgeon in charge. In men vasectomy is performed, an inch of the vas deferens being removed on either side through a small incision in the upper portion of the scrotum. The operation is a simple one and can easily be done under a local anæsthetic, but owing to the disturbed mental state of the patient general anæsthesia is usually employed. In women a small abdominal incision is made and a portion of the Fallopian tubes, about an inch long, is resected, the divided ends being buried in the peritoneum. Dr. Dickinson suggests that since an opening into the peritoneal cavity, however carefully performed, cannot be made without some risk, sterilisation in the female might be carried out through the vagina; but vaginal cœliotomy is an uncommon operation in America, and this method of approach has not been adopted. At the end of his article he discusses other possible methods of sterilisation—in males by irradiation of the testes or even by application of heat, and in females by irradiation of the ovaries, and by closure of the openings of the tubes into the uterine cavity. With one of the new hysteroscopes an operator may locate the opening of the tubes and, using an electric cautery or diathermy electrode, he can obliterate it, the success or otherwise of this procedure being afterwards ascertained by insufflation. This method has only reached the experimental stage and further observations will be needed before it can be considered satisfactory. Dr. Dickinson's paper is of interest not only because it publishes records of the largest series of sterilising operations that have ever been done, but because it shows that the Californians have found no difficulty in putting into practice their political opinion about procreation by the mentally afflicted.

A FORM OF SPLENOMEGALY HITHERTO UNDESCRIBED.

THE spleen has come in for a good deal of attention in the course of the last few years and much has been learned about its physiology and pathology. Several more or less successful attempts have been made to classify the various forms of splenomegaly and most of these can now be correlated with disturbances either of the circulatory mechanism or of the reticulo-endothelial apparatus of the organ. The forms of splenomegaly associated with disorders of the reticulo-endothelial apparatus constitute a very interesting group, including the splenomegaly of Gaucher's disease, splenomegaly of the Niemann type, and the splenomegaly coincident with various kinds of anæmia and cholesterolæmia, of which one variety, associated with diabetes, was described by Schultze nine years ago and a second, associated with chronic cholæmia, more recently by S. C. Dyke. It almost seemed that the splenomegalies had been definitely classified and that all that remained was to fill in details, but recent observations by Fiessinger, Grégoire, and Olivier,[1] of Paris, indicate that there is yet one more form to be accounted for. The source of the spleen in question was a female patient who from 1916 to 1926 suffered from increasing anæmia with progressive though slow splenomegaly. In 1926 when the spleen was removed the blood showed 30 per cent. of hæmoglobin with 1,500,000 red cells; white cells were 4000 per c.mm., the only peculiarity of the differential count being the presence of 2 per cent. of Turck's cells. Before removal the spleen reached 10 cm. below the costal margin and its weight after removal was 580 g. Operation was followed by speedy disappearance of the anæmia and a rise in white count to nearly 8000. Macroscopically the spleen showed fibrosis with no observable abnormalities. Microscopically it was characterised by the presence of enormous numbers of giant cells, some comparable in size with those usually found in tuberculous infection, others many times larger. Caseation was absent; no "epithelioid" cells were to be seen, examination for the presence of tubercle bacilli was negative, and portions of the fresh organ introduced into guinea-pigs failed to produce any infection. Many of the giant cells showed cavities in the cytoplasm containing amorphous refractive material whose nature remains obscure. The authors hazard no suggestion about the nature of this form of splenomegaly and merely state that the report has been published at the request of several hæmatologists. It is fairly clear that it belongs to the class associated with disorders of the reticulo-endothelial apparatus, but that is as far as present knowledge goes. It is interesting to note that this type of splenomegaly, though hitherto undescribed, has not gone unrecognised in this country. Sections of a spleen presenting appearances in every way comparable with those described by the French authors were passed from hand to hand at the meeting of the Pathological Society of Great Britain and Ireland in January, 1927, and aroused a good deal of interest. Details of the case were lacking, but it was stated that the spleen had been removed with good results from a woman suffering from anæmia.

THE PLAGUE MENACE IN SOUTH AFRICA.

Cape Town, in addition to having to cope with all the health problems of a British seaport, including a shortage of houses, is faced with a special danger owing to the infection of the veld rodents with plague. In his latest report on the health of that city Dr. T. Shadick Higgins remarks that in the last five years there has been a recrudescence of human plague in South Africa. In the year 1923–24 there were 372 cases in the Union, chiefly in the Orange Free State, but a few in the Transvaal, and 34 in the northern districts of the Cape Province. In 1924–25 there were 112, and in 1925–26 there were 71 human cases, with 26 in the Cape Province. In 1926–27 there were 75 cases in the Union, of which 46 were in the Cape Province. As yet there have been no human cases in Cape Town itself and, apparently, no plague infection among the rodents there. In 1923–24 the area of plague infection was still at a great distance. In 1924-25 there were human cases at De Aar, 500 miles from Cape Town; and in 1926–27 there were cases within 200 miles of Cape Town, with extensive infection of wild rodents. In January, 1928, the wild rodents, in an area about 80 miles from Cape Town and separated only by a narrow tract of country from the Cape Flats, were found to be heavily infected. Cape Town is situated in a district infested with gerbilles, which flourish in the sandy flats and are attracted to villages and farms in search of grain. A large anti-rodent staff is employed to keep them down, and the number of rats in the town and gerbilles in the surrounding country is actually far less than it was a few years ago. The staff is being increased and special attention is being given to the rat-proofing of all premises. It is generally supposed that the African breeding-ground of plague is to be found near the source of the White Nile, and that the disease is spread thence by traffic to Egypt or in other directions. The health report for Durban for 1926–27 shows that there is, at the moment, no risk there of direct

spread by veld rodents, but that special precautions are taken to reduce the possibilities of rat transference from up-country centres by rail as well as for the destruction and what is called the building-out of the rat. There, also, the staff engaged in this work has been increased. Earlier in this century California suffered from outbreaks of human plague, and there both the rats and the ground squirrels were found to be infected. In 1913–14 a million rats were destroyed in San Francisco and some 20 million ground squirrels in the neighbourhood. The rat is, of course, the most dangerous animal to man, because it comes in closer contact with him. It may be that the rat-flea is a more effective vector than the insect parasites of the gerbille or ground squirrel, although, speaking generally, all species of fleas found on rodents are capable of transmitting plague. It would appear, however, that up to now the human cases in the Union of South Africa have been chiefly contracted in the rural districts from the gerbille, and that the infection has not yet extended to the town rats.

THE progress of His Majesty the King continues to be satisfactory. The fact that the week has gone by without the issue of an official bulletin may be allowed to speak for itself.

The Services.

THE HEALTH OF THE ARMY.

THE annual report on the health of the Army for 1927,[1] which has just appeared, is less severely statistical than formerly—more ready to tell of changes in the health of the troops, and how treatment has improved. There were in 1927, 187,084 men in the Army, and, per 1000, there were 467·7 (454·8) admissions, 2·42 (2·35) deaths, and 11·4 (10·7) finally discharged invalids. The figures in parentheses are those for 1926. The chief causes of illness for officers and men are given as malaria, tonsillitis, pharyngitis, and bronchitis. Officers suffer more than "other ranks" from injuries and appendicitis. The chief cause of loss of service was venereal disease.

The principal causes of deaths among "other ranks" were injuries, 131; pneumonia, 73; suicide, 38; and tubercle of lung, 27; whilst the principal causes of invaliding were diseases of the ear and nose, 514; of the nervous system, 225; and tubercle (all forms), 203. Admissions for dengue numbered 982 (1644 in 1926), a fact which gains importance because the insect vector of yellow fever and dengue is the same. Diphtheria proved troublesome in 1927, and the report states that active immunisation was to be used in 1928. Most cases of dysentery were bacillary; for the amœbic variety emetine is still regarded as the best remedy. The incidence of enteric fever increased from 0·9 to 1·3 per 1000, 30 cases occurring at Shanghai; the unprotected had an attack-rate of 4·7, three times that of the inoculated, 1·6. Over 95 per cent. of the whole Army is now protected. Malaria is being reduced in India by keeping the troops in non-malarious hill stations, and by mosquito-proofing of barracks. Admissions in India this year numbered 7723, a reduction of 1500. The disease was said not to occur at Shanghai, but it nevertheless attacked the troops. Although the local carrier, *Anopheles hyrcanus*, does not enter the brightly lighted houses of residents, as many as 50 of these insects might often be found in each of the tents of the soldiers.

The number of cases of pneumonia reported was 672 (502), the especially fatal lobular form being particularly noted at Shanghai. "Pyrexia of uncertain origin" appears less often in the returns in proportion as tropical diseases are better understood, and an unknown, undifferentiated fever is hinted at in Egypt, and another in Jamaica. Tuberculosis of lung was this year equally prevalent (1·3 per 1000) among officers and men, slightly more than in 1926, when its incidence was the lowest ever recorded. Venereal disease, with a case incidence of 49·1 per 1000, increased by a fifth, the rates being 21·4 at home and 223·5 at Shanghai. For every 100 cases of venereal disease at home, the infections were gonorrhœa in 76, soft chancre in 5, and syphilis in 18. In India the corresponding proportions were 71, 19, and 10; and in Shanghai, 53, 40, and 7. Much is said about vaccine treatment of gonorrhœa, but the average duration of a case does not seem to shorten.

It is repeated, with examples, that no one who has had encephalitis lethargica will make an efficient soldier, being too untrustworthy; special efforts are being made to prevent the entry of men with middle-ear disease. Gastric and duodenal ulcers were as frequent as in 1926, but operations were more successful. A dozen interesting pages are devoted to the medical history of the Shanghai Defence Force (p. 120 seq.).

Operating theatres are being steadily improved; a portable X ray apparatus has been standardised, and there are ultra-violet lamps in all the larger hospitals. It is being discussed whether canteens should not be shut for two hours before dinner so that the young soldier may get more good out of the excellent food provided for him. On transports milk is made from butter, milk powder, and water. Stainless steel seems to be useful for water-bottles and salt cellars. Increased quantities of vaccines and sera are prepared, and there is an interesting note on the study of vaccinia at Woolwich. Dental work goes on briskly, and the example of the old soldier now reinforces the dentist's advice, whilst it is noted that after dental treatment recruits show increased self-respect and smartness. Medical units of the Shanghai Defence Force were the first to go abroad with complete dental personnel and equipment, and much good work was done in the transports during the outward voyage.

In spite of occasional disappointments, the good work done for many years by the officers of the Royal Army Medical Corps is bearing fruit, which will be a source of satisfaction to Sir Matthew Fell, the Director-General, who signs the report.

ROYAL NAVAL MEDICAL SERVICE.

R. C. Webster to be Surg. Lt.

The following appointments have been made:—

Surg. Lt.-Comdr. H. L. Douglas to *Assistance*.

Surg. Lts. H. S. Marks to *Clematis*, and J. J. Cusack to *Bridgewater*.

ROYAL ARMY MEDICAL CORPS.

Capt. V. J. Bonavia to be Maj.

Lt. (on prob.) W. A. R. Ross from the secd. list is restored to the estabt.

The undermentioned to be Lts. on prob.: W. F. Hannay (seconded), W. H. Scriven, from R.A.M.C. Reg. Army Res. of Off., H. G. G. Robertson, H. C. Benson (seconded), E. M. Hennessy (seconded), M. J. Mallen, H. E. Knott (seconded), J. Crealey, V. C. Verbi, R. Leaning (seconded), and G. F. Harrison (seconded).

ARMY RESERVE OF OFFICERS.

Lt.-Col. H. H. Leeson to be Lt.-Col.

TERRITORIAL ARMY.

Lt.-Col. L. A. Harwood, T.D., to be Bt. Col.

Lt. E. W. Ashworth to be Capt.

R. F. Ward, A. J. King, and J. C. Fotheringham to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. M. Coplans, having attained the age limit, relinquishes his commn. and retains his rank.

Majs. O. Teichman and I. H. Lloyd-Williams, from Active List, to be Majs.

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY.—The trustees of the late Mr. C. Heath Clark have allocated £10,000 to this institute for the promotion of education in London.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XXIV.—THE ELECTROCARDIOGRAM.

PART II.*—ABNORMAL RECORDS.

When *hypertrophy* affects the two ventricles unequally, so that the normal balance between them is upset, a characteristic alteration appears in the direction of the initial ventricular deflexions. When the right ventricle predominates (Fig. 6A) the upward deflexion R is larger in lead III. than in lead I. Conversely, when preponderance is in favour of the left ventricle (Fig. 6B) R in lead I. (R_1) and S in lead III. (S_3) are the prominent features. It is only when the heart is enlarged that a diagnosis of right or left preponderance should be made; for in hearts of normal size similar variations in the QRS complex may be due to the lie of the heart in the thorax, the transversely disposed heart of the short thick-set individual giving a record resembling that of left preponderance, while the vertical heart of the long narrow-chested subject tends to give one like that of right preponderance.

Students often ask what help the electrocardiogram can give in the diagnosis of *valvular lesions*. The answer to that question is that the form of the record may be modified indirectly when the valvular lesion is associated with auricular hypertrophy (Fig. 7) or with an alteration in the relative muscle masses of the two ventricles. Old-standing cases of aortic incompetence, for example, often show left preponderance, while right preponderance may be present in mitral or pulmonary stenosis.

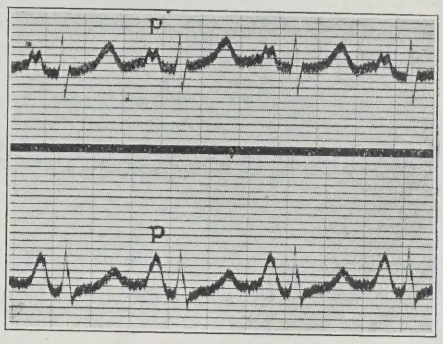
Ectopic Beats.—Variations in the amplitude and duration of the initial ventricular deflexions (QRS) are striking features in certain abnormal records. If experimentally one produces a forced beat by stimulating the apex of the right or left ventricle, the wave of excitation has to spread either through the septum or up one branch of the A-V bundle and down the other (fig. 2) to reach the opposite ventricle. It takes longer to cover the ground. Consequently the duration of the QRS group is prolonged; and, since the stimulated ventricle starts to contract before the counterbalancing electrical disturbance arises in its fellow, the initial ventricular deflexions are of unusually large amplitude.

A spontaneous *ventricular extrasystole* in the human subject is analogous to an experimentally forced beat, and the electrocardiogram (Fig. 8) consequently exhibits similar features.

Another cause of asynchronous contraction of the ventricles is a *lesion in one or other branch of the A-V bundle*. Every cycle in the record (Fig. 9) from such a case resembles a ventricular extrasystole in the increased duration of the QRS group and in the peculiar form of the T wave. When, on the other hand, an extrasystole occurs in response to an impulse arising in the auricle or A-V node, the stimulus reaches the ventricles by the normal pathway, and consequently only the auricular complex (P) is modified. A series of such premature beats constitutes what is called a paroxysm of tachycardia (Fig. 13). In health the rapid ventricular deflexions are sharp and clean. R and S waves which are notched or slurred in either lead I. or II. are abnormal.

Heart-block becomes a fascinating subject when studied electrocardiographically. In its mildest form it cannot be recognised without the aid of graphic records, for the rhythm of the heart is undisturbed, though the normal pause between the commencement of the auricular and ventricular contractions is prolonged. This is depicted graphically by lengthening of the "P–R interval," which in health (except in athletes) never exceeds 0·2 sec. Heart-block of a more severe grade is characterised clinically by the occurrence of intermissions in the pulse. The mechanism of this disturbance is very beautifully shown in the electrocardiogram. In the third cycle of Fig. 10 the P–R interval is less than $\frac{1}{5}$ sec. In the fourth it is almost 3/10 sec., while the fifth impulse (P_5) is completely held up and fails to reach the ventricle. This sequence of events is precisely repeated in the next three cycles. A record such as this gives one a remarkably vivid picture of what is taking place. The

FIG. 7.



Auricular hypertrophy. The P wave is notched in lead I. and of unusually large amplitude in lead II.

series of auricular impulses is like a convoy of wagons crossing a muddy swamp; each wagon makes the ruts deeper, the going becomes heavier and

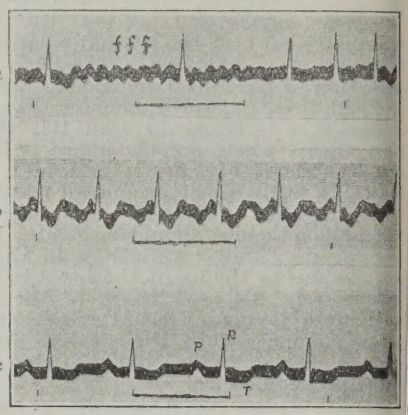
Ventricular extrasystoles (Ex.) follow each normal beat (R). (3 m.v. = 2 cm.)

heavier, till eventually the road is no longer passable, and the next wagon has to wait until temporary repairs have been carried out.

Auricular Fibrillation.—Electrocardiographic control of the treatment of auricular fibrillation with quinidine affords another glimpse behind the scenes. Hour by hour, as the heart comes more and more under the influence of the drug, we can watch the gradual increase in duration and regularity of the auricular wavelets (fff, Fig. 11, *a*) marking the transition from fibrillation to flutter (Fig. 11, *b*), and enabling us to trace the relationship of two conditions which clinically appear so widely different. The enemy is gradually withdrawing from his outer defences as the bombardment grows hotter. Then suddenly a shell bursts in the very midst of his magazine. The day is won. Normal rhythm has been restored (Fig. 11, *c*).

FIG. 11.



Three records from a case of auricular fibrillation treated with quinidine: (*a*) fibrillation; (*b*) flutter; (*c*) normal rhythm. Black line under each record = time interval of 1 sec.

Conclusion.

Heart-block and fibrillation are but two examples of the romance of electrocardiography; there are many others. A single case may serve to illustrate the clinical importance of this investigation in diagnosis and prognosis. A stout and pampered invalid of 66 had suffered for 15 years from pain in the chest, in addition to various other ailments. There was nothing abnormal to be found on physical examination of the cardiovascular system. The highly strung nervous temperament of the patient, and the fact that the pain frequently came on when lying down, and could be relieved by standing up and walking about had led her doctor to discount the subjective symptoms, and to label the case "pseudo-angina." An electrocardiogram, however, revealed bundle branch block, a finding which completely reversed the prognosis, and the patient died suddenly a month later.

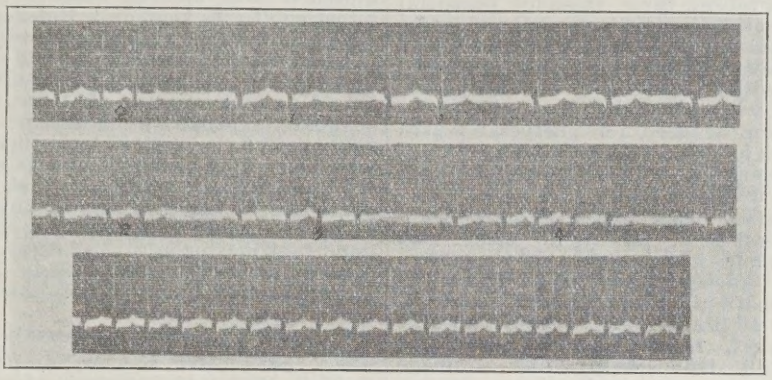
No one is likely to question the importance of the advances in our knowledge of the disorders of the cardiac mechanism which we owe to the electrocardiograph; but, since it is the function of the practitioner to combat disease, he will naturally ask, "How can this instrument help us in the diagnosis and treatment of our patients?" The answer to that question is that the electrocardiograph can often furnish definite objective evidence regarding the condition of the all-important heart muscle; and what is more, it can sometimes do so when other methods of examination are almost, if not completely, impotent. It is not only in the more complicated disorders of the cardiac mechanism, such as that illustrated in Fig. 12, but also in cases where the history is inconclusive and the physical examination yields little help, that the additional evidence furnished by the electrocardiogram may be of so much value. A normal electrocardiogram, on the other hand, does not necessarily signify a normal heart. As in the case of the Wassermann reaction, it is only a positive finding to which one can attach much weight. In conclusion one must emphasise the importance of remembering that electrocardiography like all laboratory methods of diagnosis is merely supplementary to the clinical investigation, and that the results obtained must always be considered in conjunction with the clinical evidence. In diagnosis electrocardiography, like radiography, may hold the casting vote; but the ordinary clinical methods are necessary to form a quorum.

FIG. 13.



These three records were taken from the same patient at the same sitting. The upper record shows single extrasystoles (1), the middle record groups of two (2), three (3), and four (4) extrasystoles, and the lower record a paroxysm of tachycardia, in which the ventricular complexes are similar in form to those of the extrasystoles in the upper two records.

CRIGHTON BRAMWELL, M.A. Camb., M.D. Manch., M.R.C.P. Lond.,
Assistant Physician to the Manchester Royal Infirmary.

PROBLEMS OF MATERNITY AND CHILD WELFARE.

GROUP MEETING OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

MANCHESTER, FEB. 21ST TO 23RD, 1929.

AT a meeting of the Maternity and Child Welfare Group, held at Manchester and presided over by Prof. LOUISE MCILROY, the first session was given up to a discussion on

Puerperal Fever.

Prof. W. FLETCHER SHAW, in the opening paper, dealt with autogenous and exogenous sources of infection. He believed, from his clinical experience, that autogenous infection was very rare, and that most cases of sepsis were exogenous, though some were not controllable by, or attributable to, the medical or nursing attendant. The husband was one factor, the patient's own dirty hands another, and the handywoman a third. It was dangerous to exaggerate the importance of autogenous infection because it might lead to less care. In teaching he would almost disregard autogenous infection and work for the prevention of exogenous infection by insisting on careful preparation of the hands of nurse and doctor. Attendance on midwifery cases in unsuitable homes was apt to induce a hopeless attitude towards asepsis. If the same attitude were adopted in surgery we should soon be back in pre-Listerism. Every case of puerperal infection was a reason for close self-examination by the attendant. He believed that the tar derivatives had done much harm—partly because they were used in dilutions which were quite ineffective. He would like to go back to perchloride and biniodide. Turning to administrative measures, he held that to ensure early recognition of disproportion by antenatal work was a difficult task even for a practised obstetrician, who was able to discover his errors in antenatal work by following up his cases; the young, inexperienced, whole-time practitioner who frequently conducted antenatal clinics was not able to follow his cases and learn from his errors. The Government had stepped in ineffectively. Diagnosis was comparatively easy, but there was no proper hospital accommodation available. He did not believe in cases of puerperal fever being treated in fever hospitals, where the medical staff might or might not be interested in obstetrics. For rural cases frequently the only provision was an isolated fever hospital. At present consultant obstetricians had no opportunities for clinical research in wards, but only on sporadic cases.

The need for better training of the practitioner was realised, but the public must also be educated. Antenatal clinics should be staffed by the obstetricians who were going to see the cases through; those who held the antenatal clinics must know the ultimate result of the labours. The young well-trained administrator might be better versed in modern midwifery than some of the general practitioners, but he should use his knowledge in a helpful rather than in a critical way. Treatment should be carried out by those who were clinically interested in this work, and antagonism between the administrator and the clinician must cease.

Prof. H. B. MAITLAND said the *Streptococcus hæmolyticus* was the chief bacterial offender; carriers of this organism were quite common. The same toxin was produced in scarlet fever, puerperal fever, and erysipelas; it might be logical to apply the Dick test and the use of scarlet fever antitoxin in pregnancy. Immunity to the toxin did not imply immunity to the streptococcus infection, but something useful might result from the establishment of toxin immunity in pregnancy, even if antibacterial immunity could not be obtained.

Dr. F. H. LACEY described methods of avoiding vaginal infection in the later months of pregnancy. He urged medical practitioners to employ midwives and not handy-women. Midwives should be subsidised,

and sterilised outfits should be provided. Both medical student and midwife needed to obtain experience in puerperal fever. Separate hospital wards should be provided for cases regarded as specially liable to sepsis before admission. Tactful administration was needed; early notification and early treatment had not been secured. During the previous three days he had seen in consultation three cases of puerperal sepsis which were notified only when moribund. One of the best hospitals he had seen was at Norton, Sheffield, not a fever hospital. Antenatal clinics should be conducted by expert obstetricians, preferably in connexion with maternity hospitals; fever hospitals should not be used for puerperal sepsis. From his experience he could say that the services of the consultants appointed in the Manchester neighbourhood were not utilised.

Dr. J. H. KERR stated that Monsall Hospital had a well-trained puerperal unit; he saw no reason why fever hospitals should not be used if they were provided with an efficient staff. Dick tests and subsequent immunisation during pregnancy should be tried; it might be advisable to have separate wards for Dick-positive cases. He described the advantages of Dr. Remington Hobbs's glycerine drainage treatment, and also its contra-indications. It was desirable that the coroner and medical officer of health in conference should have power to order a post-mortem examination in all deaths occurring within 28 days of childbirth. Clinical pathologists might be called in consultation before the gynæcologist, who would then have the pathological report before them.

In the general discussion which followed the limited use of the consultants provided was confirmed, also the want of coöperation between the administrators and the obstetricians. The investigation of puerperal deaths was discussed and complaints of overlapping of officials were ventilated. There appeared to be general agreement that investigations at the home should be carried out by a senior medical administrator. As regards antenatal clinics, it was claimed that they were only a stopgap till a better obstetrical service had been secured, and that some benefit was obtained even if the medical officer in charge was not always able to follow up his cases. It was pointed out that whole-time officials were often appointed because the general practitioners would not do this work.

The PRESIDENT claimed that the statistics needed to be put on a proper basis. She considered that teeth were quite important as an autogenous source of infection. She described the methods adopted at the Royal Free Hospital, where septic (except V.D.) cases were detained for treatment, but were kept in separate wards. Open-air treatment and colon lavage had been found beneficial. It was necessary to have postnatal as well as antenatal clinics. She strongly favoured the glycerine treatment in suitable cases. She believed resistance to infection was lowered by prolonged labours and advocated a greater use of sedatives and anæsthetics. The investigation of maternal deaths must be carried out tactfully and by a medical practitioner.

Other Topics.

Dr. C. P. LAPAGE dealt with endocrine deficiency in children and also brought up to date the information given by him in THE LANCET (1926, i., 176) with respect to pink disease. Since his first case in 1923 he had now seen about 70, only three of which had been diagnosed beforehand. At present this disease was not known to practitioners, but only to hospital residents. Any practitioner who had once seen a case would not miss another. Most of the children were under three and some were entirely breast-fed. There was seldom more than one case in a family; the infectivity appeared to be on a par with that of poliomyelitis. A few cases died from broncho-pneumonia but 90 per cent. recovered, though occasionally not for a year. The cause and pathology were still mysteries. Some of the names given to the disease were misleading, because polyneuritis and œdema were not constant symptoms. He suggested "acroerythema." As to treatment, as yet good nursing and keeping warm were the main things.

Dr. M. J. ROWLANDS dealt with the effects of vitamin B deficiency on the intestinal tract and illustrated his lecture with lantern slides of the dilatation of the stomach and the atrophy of the muscular and mucous coats of the stomach and intestine of rats kept on a B-deficient diet. Further slides showed the resulting intestinal stasis and the progress up the lacteals of specific bacteria fed to those rats in broth. Applying these results to human beings, Dr. Rowlands suggested that they afforded an adequate explanation of the bearing of intestinal toxæmias on rheumatoid arthritis and of the route by which the colon bacillus found its way to the bladder, via the lymphatic system, in that disease. A similar dilatation of the stomach in human beings as the result of vitamin B deficiency would obviously be an important matter in cardiac cases. He believed that modern diets were more likely to be deficient in B-vitamin than in any of the other vitamins.

SECOND SESSION.

At the second session, presided over by Dr. F. T. H. WOOD, the discussion turned on the

Diet of the Young Child.

Prof. STUART COWELL led off with an exposition of the views held by research workers as to the dietetic needs of the young from conception to adolescence. He gave as evidence that all was not well: the poor physique of many of our urban children, the liability of the young child to intestinal, respiratory, rheumatic, and tuberculous infections, to disorders of calcification, such as rickets and ill-formed teeth (with effects lasting through life), and to enlarged tonsils and adenoids. He showed the need for a diet for the child (supplied through the mother from conception to weaning) which contained sufficient vitamin D and calcium, sufficient vitamin A to promote resistance to infections, sufficient iron to guard against nutritional anæmia; in goitrous districts iodine should be given under medical direction. He went on to indicate from what foods these various requisites could be obtained. The main error in children's diets was the deficiency of the fat-soluble vitamins A and D. The distribution of these vitamins was similar except that the amount of vitamin D in green vegetables was negligible. For safety extra vitamins should be given to breast-fed as well as to bottle-fed infants in the forms of cod-liver oil (beginning with a quarter of a teaspoonful a day at 2 weeks old, increasing to one teaspoonful at 3 months and 3 teaspoonfuls at 9 months, to be continued throughout young childhood), egg-yolk in small quantities (for its iron content) from the third month, and orange-juice. Mrs. May Mellanby had shown that vitamin D was not only essential for building good teeth, but also had the power of preventing the extension of decay in children's teeth. The anti-calcifying elements in such cereal foods as wheat germ and oatmeal should be counteracted by specially abundant supplies of both vitamins A and D. Unbalanced wheat germ, if given in considerable quantity, might produce permanent degenerative changes in the spinal cord. He was not convinced that there was any widespread vitamin B deficiency in this country. If there was reason to suspect B deficiency in individual children he thought it was wiser to give some yeast preparation, such as marmite, which contained vitamin B_2 as well as B_1, rather than cereal germ which contained chiefly B_1 (the antineuritic element) and possessed the toxic properties just mentioned. Prof. Cowell believed that the improvements in the standard of nutrition and physique were within reach if the comparatively simple measures founded on recently acquired knowledge were adopted.

In the discussion which followed the defenders of oatmeal brought the reply from Prof. Cowell that its toxic effects could be counteracted by plenty of milk and eggs.

Dr. CATHERINE CHISHOLM questioned the need for

giving egg-yolk to breast-fed infants. She found it possible to give chopped raw greenstuffs to babies in their first year. She advocated plenty of water and had great faith in cod-liver oil.

Dr. GEORGE G. CAMPION, speaking as a dental surgeon, was convinced of the truth and importance of Mrs. Mellanby's work. To some extent dentists were divided as to the relative importance of food and function, but these two schools of thought were not really contradictory but complementary.

Dr. H. SCURFIELD thought a better dietary was the most important item in public health advancement. Up to 1910 the feeding of the ex-baby was a matter of old wives' tales. They did not yet know what a weaned infant was ready to digest. For example, some pediatricians were afraid of bananas, but others found that, if crushed, they were good for infants a few weeks old. He commended a paper by Dr. Clara M. Davis on Self-selection of Diet by Newly-Weaned Infants [1] as worthy of consideration.

The PRESIDENT suggested that the Group might take in hand the preparation of dietary tables.

Visit to the Manchester Babies' Hospital.

Among the visits paid by the members to institutions was one to the Manchester Babies' Hospital. This institution, opened in August, 1914, as a 12-cot hospital for babies suffering from disorders of nutrition, has developed into a model hospital with specially built open-air wards, equipped with every scientific device and accommodating 80 babies. The nursing staff, including probationers, numbers 40 and there are in addition three wet nurses for premature infants. A cot and apparatus used for the supply of atmospheres enriched by oxygen and carbonic acid to infants suffering from certain forms of infantile atrophy was demonstrated by Dr. Edith McCrea. Some 30–40 infants, which had had a stationary weight for months without any discoverable cause and had not responded to other treatment, had during recent months gained weight on this régime.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Voluntary Hospitals.

LAST year, after an interview with the Secretary of State, a Liaison Committee was formed by the Scottish branch of the British Hospitals Association. The intention was that this committee should keep in touch with the Department of Health so that the Department might be kept aware of the policy of the voluntary hospitals. At the same time, the Scottish Regional Committee of the British Hospitals Association would continue their work of organisation and coördination of the Area Committees. At a recent meeting in Glasgow there seemed to be a little confusion between the functions of those committees. This, however, will clear itself up; since the Liaison Committee is meant to represent all the area committees of the various localities. An important point of the meeting was that general agreement was expressed that the new clauses in the Local Government (Scotland) Bill were satisfactory in that, under the new arrangement, the poor-law stigma would no longer affect hospital admissions. Colonel Mackintosh said that at the first meeting of the Liaison Committee, Major Elliot submitted a proposal, put forward by the Corporation of Glasgow, to empower the local authorities to remove hospital service entirely from the poor-law and to provide hospital treatment for all kinds of sickness, as in England and Wales. As representatives of the voluntary hospitals, said Colonel Mackintosh, the Liaison Committee could not stand for discrimination in quality of hospital treatment between paupers and non-paupers. They recognised that the only way to avoid that was to remove hospital treatment from the poor-law, and that that could only be done by conferring on the Scottish authorities the same general powers as the English authorities. This step was inevitable and, indeed, the removal of the poor-law stigma was one of the conditions of full coöperation between voluntary hospitals and the public authorities. They could not contemplate the growth of a general hospital service which would prevent complete coöperation with the voluntary hospitals, but they advised the removal of the hospital service from the poor-law, under conditions that would provide as full safeguards as possible for the voluntary hospitals. As a result of their meetings with the Department of Health, a new clause had been provided with a view to removing the poor-law stigma from hospital service, and the Scottish voluntary hospitals would secure in the new clause provisions that substantially safeguarded their future place in the scheme of hospital service. With that new power the way was now open for full coöperation in hospital service. Col. Mackintosh's statement marks a very important departure in Scottish hospital coöperation. It is satisfactory to know that, under the new Bill, the whole problem passes on to a more satisfactory plane.

Glasgow Hospital Sunday Fund.

The Glasgow Hospital Sunday Fund shows a slight decrease on the £10,000 collected in 1927. The number of churches contributing was 555, against 522, and the number of Sunday schools was 310 against 301. The average amount per church was £15 17*s.* 10*d.*, as against £17 8*s.* 10*d.* in the previous year; but the average per Sunday school was £3 7*s.* against £3 2*s.* It is interesting to note the relative contributions of the leading churches. Thus the Church of Scotland contributed £2611; the United Free Church, £4300; the Roman Catholic Church, £499; the Episcopal Church, £192. It is also interesting to recall that the great Dr. Chalmers, in his famous parish of St. John's, maintained that the Established Churches ought to support their own poor. He was entirely opposed to the poor-law rate, but was at the same time in favour of public free education. This was before 1845. In spite, however, of the rating system of poor relief, the voluntary hospitals have steadily received contributions from all the leading churches, but the hospital finance of to-day is a gigantic thing compared with what it was in Dr. Chalmers's day, and his parochial proposals could not face the poor-law or Unemployment or Health Insurance of our modern communities. Under his inspiration St. John's parish did marvels; but his efforts were only a beginning, and even poor-law problems, as understood to-day, were hardly known. It is well to keep these facts in mind when comparing superseded systems with the larger systems that developed from them.

The Glasgow Western and the Glasgow Victoria, like the Royal Infirmary, show slight decreases on their contributed income; but this is only to be expected after so many years of serious unemployment.

The Sick Light-keeper on Pentland Skerries.

Owing to the serious gales, there has been great difficulty in conveying advice to the sick lightkeeper on Pentland Skerries. This is one of the most difficult rocks in the North Sea. Normally, mails and provisions are sent by boatmen from South Ronaldshay, five miles off; but in the emergency this was impossible. The keepers at the Pentland Skerries have a wireless receiving set, but not a transmitter. The symptoms of the sick principal were signalled by morse lamp to the boatman at Broughness, and then transmitted to Stromness by telephone. A doctor was able, at stated hours, to send instructions from the northern lighthouse transmitting station at Stromness. For several years the Highlands and Islands Medical Service section of the Scottish Board of Health, now the Health Department, have assisted the local telephone service between islands; but the lighthouses are under the direct management of the Northern Lights Commissioners. The local expense

[1] Amer. Jour. Dis. Child., 1928, xxxvi., 651.

of transmitter equipment has been a standing difficulty and, in spite of the coöperation of the War Office and the Post Office, some localities are still inadequately provided for.

Queen's Nurses.

In the recent appeal for the Queen Victoria Jubilee Institute for Nurses and the Scottish Nursing Associations, Scotland has on the whole done well. As a national memorial to Queen Alexandra more than £87,000 has been subscribed in Scotland, this sum being more than a third of the gross amount of £233,086 collected in Great Britain, Northern Ireland, the Irish Free State, and the Dominions Overseas. The figure aimed at was 7*d.* per head of the population, and this was exceeded in many counties; but the general strike and the coal strike affected the collection adversely. The amount available for the Queen's Institute itself is nearly £47,000. Queen's nurses, it may be noted, are steadily increasing their work for the various health authorities, and the process thus established will be materially accelerated under the new system of local government.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

A Cancer Campaign in Queensland.

DURING the last 15 months more than £50,000 has been collected in response to an appeal for funds to extend the facilities for the treatment of cancer in Queensland. A good deal of publicity has been given to the appeal by the daily press, and popular education in the detection of early signs of cancer, the available methods of treatment, and the danger of "quack" treatment has been carried out by lectures and articles. The campaign is now about to be closed, and the funds collected will be handed over to an appointed trust.

The original intention of the campaign committee, whose president is Dr. E. Sandford Jackson, was to set up a treatment centre in the State capital. This was to be modelled on an institution at Toulouse in France, and the estimated cost was £28,000. The proposal was later modified in favour of providing modern installations for radium and X ray treatment at existing hospitals; it was thought that cancer patients would more readily attend a general hospital than a cancer hospital, whilst early cases are more likely to go to the out-patient department of a general hospital than to a special clinic. The first installation, which was officially opened on Dec. 20th, is now in operation. It consists of a deep X ray therapy plant at the Mater Misericordiæ Public Hospital, Brisbane. The plant is capable of generating 300,000 volts, and the cost was £3500, which includes the cost of installation. Half a gramme of radium has been purchased by the committee for use throughout Queensland. The cost was £6000, and a further £1000 will be spent on insurance, needles, and applicators. Through the good offices of the Governor of Queensland, Lieut.-General Sir John Goodwin, the radium was obtained through the British Empire Cancer Campaign. Sir John was until recently the honorary organiser of that campaign, and the Queensland Committee owe much to his tactful guidance.

The committee are concentrating mainly on the therapeutic aspect of cancer. While accurate records will, of course, be kept, research is limited in Queensland because there is no medical school in the State University. The main difficulty which they have to contend with is the provision of treatment facilities over a very large area (670,000 square miles) with a scattered population (914,000), of whom over half live in the cities, and 32 per cent. in Brisbane alone. It will ultimately be necessary to equip the hospitals at the country centres of Toowoomba, Rockhampton, and Townsville with deep X ray and radium facilities. The Commonwealth Department of Health has already established laboratories at these centres, and the pathological work can thus be performed efficiently. Blair Bell's lead treatment was recently studied by two members of the committee, Dr. Graham Brown and Dr. L. M. McKillop, who were given extensive facilities during their visit to England. The preparation of therapeutic compounds of lead has been begun in Australia.

Judging from personal observation, the public have responded to the instruction about the early signs of cancer. In the dry, hot, and sunny plains of Western Queensland, basal-celled carcinoma (rodent ulcer) of the face, and less so of the hands, is comparatively common. This is attributed to the long-continued exposure to the sun, and the insufficient protection of the face afforded by the narrow-brimmed felt hat in common use. As an offset to this incidence, tuberculous lesions of the skin are extremely rare; in fact, surgical tuberculosis is practically unknown, although pulmonary tuberculosis is fairly common.

MEDICINE AND THE LAW.

Advertisements of Abortifacients.

SOME of the advertisements of alleged remedies for female complaints which newspapers publish are little better than incitements to criminal abortion. It would be a nice legal question how far the newspapers concerned could be indicted as accessories before the fact. Parliament has hitherto not prohibited such advertisements as those of venereal disease remedies were prohibited in 1917; the only possible restriction, therefore, is by voluntary action on the part of the organised bodies of the newspaper and advertising world. The Advertising Association, over which Lord Riddell presides, has issued a most important memorandum to the Press of the country on the advertising of abortifacients. The memorandum frankly emphasises that so-called "irregularity" in a woman is in the great majority of cases a symptom of pregnancy; in the other cases it is probably a symptom at least of a condition requiring skilled medical treatment and sometimes of serious disease. A warning that the advertised "remedy" is not to be used by pregnant women is particularly mischievous as it will amount to a positive inducement to acquire the remedy for the purpose of abortion. The memorandum remarks that the Advertising Association has consulted the Director of Public Prosecutions concerning the advertisement of remedies for female "irregularities" and that he has expressed the firm opinion that such advertising is a serious source of danger to those whom it reaches, and has stated that it is being closely watched by his department. The memorandum also recalls the fact that witnesses before the Parliamentary Select Committee on Patent Medicines made it clear that in most cases these advertised "remedies" are definitely and deliberately purchased where pregnancy is admitted or suspected in the belief that they will terminate that condition. Finally the Advertising Association, after recognising that many newspapers already exclude mischievous advertisements of this sort, calls upon the Press as a whole, and upon all advertising agents and others concerned, to decline to accept any advertisements of drugs or treatment purporting to be remedies for disorders generally termed irregularities, female ailments, or women's complaints. This action will be generally approved by competent opinion as a public service of great value to the community. The indirect effect of the memorandum will not be inconsiderable, for, if any advertising agent or newspaper manager found himself within the reach of the law he would no longer be able to plead ignorance of the effect of the offending advertisement. The action of the Advertising Association will have made the publication of such advertisements in future a particularly deliberate act. If the memorandum does not have the full success which it deserves it will really be desirable for Parliament to take notice of the minority of newspapers which ignore the warning.

Correspondence.

"Audi alteram partem."

OPERATING FOR APPENDICITIS.

To the Editor of THE LANCET.

SIR,—In his Hunterian lecture, published in your last issue, my friend, Mr. McNeill Love, gives some interesting figures concerning the treatment of appendicitis, but I confess I am unable to make out exactly what cases are included in the group treated by expectant methods. Just before Table I. he speaks of "an analysis of the remainder," but under the heading "Treatment of General Peritonitis," he says:—

"In cases of general peritonitis, appendicectomy certainly appears to be the rational treatment, rather than temporising with a perforated or gangrenous appendix, which provides a constant stream of infection."

Are we to conclude, then, that the cases of general peritonitis were excluded from the "remainder," and operated upon as a matter of course and, if so, with what mortality? Even the mortality of 3·8 per cent. given for the total of 607 cases treated expectantly is not the final index of the risks these patients ran, for there may have been some mortality following the subsequent operation for the removal of the appendix. (I had two deaths among my first 618 cases of interval removal). There may also be some of the patients who refused to have the *fons et origo mali* extirpated, who will subsequently lose their lives as the result of an attack of appendicitis, while I take it that the survivors among those who fortunately recovered after the hazard of an immediate operation were ridded of the cause of subsequent appendix trouble.

Even if statistics can be made to prove anything, they are at least some sort of a standard for comparison, and are ever interesting. It has always been my practice to regard acute appendicitis as an emergency requiring surgical intervention. The exact period at which to intervene, and the scope of the operation, I hope have been the subject of an informed discrimination rather than rule-of-thumb, but I have never deliberately advocated the expectant method as an alternative to operation. Over 20 years ago I commenced to classify my cases, as in the following table, and though it may sometimes be difficult to decide in what group a case should be placed, it matters less when the whole of the results are presented.

All Cases of Appendicitis to End of 1928.

Group	—	Cases	Deaths	Percentage
	Acute appendicitis:			
1	without peritonitis ..	135	0	—
2	with localised peritonitis ..	395	4	1
3	with flank or pelvic peritonitis, or both	206	16	7·7
4	with diffuse peritonitis ..	95	28	29·0
5	with residual abscess ..	64	5	7·8
6	with primary localised abscess	424	14	3·2
7	interval removal	913	3	0·3
8	with primary complications	20	9	45·0
	Total ..	2252	79	3·5

The list includes all the cases on which I have personally operated up to the end of 1928. Group 5 consists of cases in which there has been some unlimited peritonitis which has subsided and left an abscess. In group 6 the abscess has developed around the appendix wherever situated, and has been localised from the start. Group 8 includes cases such as acute intestinal obstruction and pylephlebitis, hence the high mortality, but since an existing acute appendicitis was the primary lesion, they cannot fairly be excluded.

I should prefer that your readers should analyse the figures as they wish. If we exclude the interval removals in Group 7, we obtain a grand total of 1339 cases of acute appendicitis, with 76 deaths, a mortality of 5·7 per cent. In these days, with so many men in the profession who have been trained since the problem of the diagnosis of appendicitis has been fairly well understood, I think we have a right to expect that the great majority of cases should reach the surgeon in Groups 1, 2, or 3. In my series this gives a total of 736, with 20 deaths, a mortality of 2·7 per cent. Cases must sometimes go on to develop abscesses, but even so the combined abscess groups (5 and 6) give 488 cases with 19 deaths, a mortality of just over 3·8 per cent.

One or two other points. Under the heading of Criticisms of Delayed Treatment, Mr. Love speaks of the method of drainage to be employed when a gridiron incision has been used. This incision is in every way unsuitable for cases that may require drainage, and surgeons who employ it in these cases will get such a heightened mortality as may well be a factor in converting them to the expectant method. I do not think Mr. Love mentions Battle's incision, but I know that this is frequently employed in the South of England, and is almost as unsuitable for dealing with appendix abscess as the gridiron, and has probably a very adverse effect on the mortality. The oblique muscle-cutting incision of Rutherford Morison[1] gives by far the best approach in acute appendicitis, and is especially useful in dealing with abscess cases. May I say to Mr. Love that ". . . to literally *tear out* (my italics) two appendices which were firmly matted and behind a turgid cæcum," may well have been the cause of the deaths of the two patients, but it was not surgery.

I am sorry I have not the time to comment on the other questions dealt with in Mr. Love's interesting and important lecture.

I am, Sir, yours faithfully,

G. GREY TURNER.

Newcastle-upon-Tyne, Feb. 25th, 1929.

TUMOURS OF THE SPINAL CORD.

To the Editor of THE LANCET.

SIR,—Dr. Theodore Thompson's interesting article on Leptomeningeoma of the Spinal Cord in your issue of Feb. 16th contains some statements which show that old-established error dies hard. With regard to the cerebro-spinal fluid he says first, that "it is generally assumed that the cellular content of the cerebro-spinal fluid below a spinal block produced by a non-inflammatory lesion such as a tumour remains unaltered." This assumption was made by Nonne in 1910, but much has been written on the subject since his paper on the Compression Syndrome, which has shown that this and several other assumptions which he then made were incorrect. For example, the "compression syndrome" as defined by Nonne often results from subacute and chronic meningitis without compression. The absence of cells does not prove the non-inflammatory nature of the spinal block any more than the presence of cells excludes the diagnosis of tumour. Next Dr. Thompson perpetuates the curious error that the syndrome described by Froin in 1903 was characterised by "a normal or but slightly raised cell count." The contrary is the case, as Froin specifically mentioned the presence of "lymphocytose" as constituting the third element in the syndrome along with "xanthochromie" and "coagulation massive." Dr. Thompson also speaks rather loosely of "spontaneous coagulation" which is not by any means the same thing as "coagulation massive" or "en masse" as Froin described it. Some spontaneous coagulation in a yellowish fluid may be present in cerebral as well as in spinal tumours, and is common in a variety of other conditions; "coagulation en masse" is much more rare, and is confined to spinal conditions of which the commonest is spinal block. If the term "syndrome of Froin" is to be retained,

[1] THE LANCET, 1901, i., 533.

it should surely be limited to its original significance, or at least confined to fluids which are very highly albuminous, in which case one might use some such term as "modified syndrome of Froin." Froin's cases were, of course, not cases of spinal tumour, but of subacute meningitis probably of syphilitic origin.

Dr. Thompson then speaks of "increase of mineral salts" in such fluids. If by that term he refers to calcium he is correct, but sodium chloride is also a mineral salt and it is constantly below the normal percentage in highly albuminous fluids. He is also somewhat inexact in his reference to the Queckenstedt phenomenon, which he includes among "general methods for raising the general pressure in the (subarachnoid) space." The value of Queckenstedt's method of compressing the jugular veins is that the increased pressure which it causes is limited to the contents of the cranium and may be transmitted thence to the spinal theca in the absence of spinal block. Anything which raises the *general* cerebrospinal fluid pressure, such as coughing or holding the breath, or compressing the patient's abdomen, will cause a rise in the lumbar manometer whether spinal block is present or not. In fact the evidence given by the Queckenstedt method is most definite when coughing causes a rise in the manometer but jugular compression does not.

Again, why does Prof. Turnbull use the obsolete term "gliosarcoma" in describing a typical neurofibroma? Whether the view be taken that these tumours are fibromas growing from and attached to nerves, or tumours derived from some more specifically nervous tissue such as the sheath of Schwann, the name "neurofibroma" is equally applicable and it is consecrated by many years of use. The more modern terms "neurinoma" or "Schwannoma" imply subscription to definite theories as to the origin of the tumour, and, until these theories are proved, should be avoided. But it seems unnecessary to retain such a meaningless term as "gliosarcoma."

As a final question, why is the name "leptomeningeoma" used in the title of the paper, when one of the tumours arose from a nerve root and the other two from the dura mater?

I am, Sir, yours faithfully,

J. G. GREENFIELD.

Pathological Laboratory, National Hospital, Queen-square, W.C., Feb. 19th, 1929.

THE NUCLEUS OF THE CANCER CELL.

To the Editor of THE LANCET.

SIR,—In reading Sir Charles Ballance's interesting historical sketch of the present position of the cancer problem, I notice that he mentions "nuclear degeneration" as characteristic of the cancer cell (THE LANCET, Feb. 16th, p. 323). After prolonged study of cancer cells in the living condition, with dark-ground illumination and with various methods of staining, I have come to the conclusion that the nucleus of an actively growing epithelial cancer cell shows no sign of degeneration. Indeed, the nucleus itself seems larger than the nucleus of the normal epithelial cell from which it has been derived.

Other facts point in the same direction. Epithelial cancer cells have a high lecithin content. Thus, if a small portion of cancer tissue be kept in a closed cell in normal saline, myelin lecithin threads are seen to develop from and around the edge of the tissue. Cancer cells show well-marked Golgi bodies. In this connexion Ludford and Cramer's observations (summarised in the same issue of THE LANCET, p. 351) on the altered position of the Golgi body in thyroid cells in exophthalmic goitre are very significant. Whatever may be the ultimate nature and origin of the Golgi body, the fact that its position and orientation in the cell give some indication of the direction of secretionary flow may have important bearings on the cancer problem. In the Mitchell Banks Memorial Lecture, and in various communications to medical journals, I have shown that epithelial cancer cells, like some normal epithelial cells, elaborate definite, and, in some cases, considerable amounts of a substance which has a very strong affinity for, and stains a mauve colour with, iodine. Although the exact composition of this iodophil substance is not definitely known, its presence in epithelial cancer cells and in *certain* sarcoma cells, as in leucocytes and some other cells, is characteristic, not of degeneration, but of cellular activity. No doubt dead and partially devitalised cancer cells can be obtained from the central portions of any cancerous tumour which show clear evidence of nuclear degeneration, but the actively growing cells at the margin, with their capacity for cell division, do not present such changes.

I notice that Sir Charles Ballance does not favour attempts to educate the lay public on the subject of cancer. We shall all agree with him in desiring the intensive education of the family doctor in all newly discovered facts which may aid him in making an early diagnosis. But our experience at Leicester, as indeed throughout the country, is that a marked reluctance on the part of patients to seek early advice is mainly responsible for the loss of valuable time. The further education of the doctor will be of little avail unless sufferers from cancer, real or suspected, can be induced to seek advice. We hope that our local cancer committee, established under the joint auspices of the municipal health authority and the Leicester Royal Infirmary, with its associated cancer control clinic, is doing something by educational methods to remove this reluctance, and thus to bring about the earlier recognition and treatment of the disease. It has, at any rate, been instrumental in dispelling from the minds of a number of persons who have sought its help, but who were found on examination to be free from cancer, that "fear and dread" which Sir Charles Ballance so rightly deplores.

I am, Sir, yours faithfully,

Leicester, Feb. 21st, 1929. C. J. BOND.

VIRILISM DUE TO HYPERNEPHROMA.

To the Editor of THE LANCET.

SIR,—We have been asked, for the sake of future reference, to give a further note on a Case of Virilism due to an Adrenal Cortical Hypernephroma. The case was reported as a successful operation for the removal of a malignant adrenal tumour in THE LANCET of Oct. 8th, 1927 (vol. ii., p. 745). At that time the symptoms had entirely disappeared; unfortunately, this satisfactory condition did not persist. In November, 1927, symptoms of virilism recurred and a mass of growth was palpable under the right rib margin; an operation showed that this tumour was quite beyond the reach of surgery, and it was decided to give the patient a course of deep X ray therapy. Death occurred on Nov. 2nd, 1928.

We are, Sir, yours faithfully,

C. G. MURRAY,

Sheffield, Feb. 24th, 1929. GRAHAM SIMPSON.

DESIGNATION OF WHITE BLOOD CELLS.

To the Editor of THE LANCET.

SIR,—More in sorrow than in anger one cannot help reflecting after reading Dr. A. T. Todd's article on a case of *Bacillus abortus* infection in the last issue of THE LANCET (p. 388) how poor indeed must be the English language if it is found necessary to borrow German words to designate the various white cells in making a differential blood count. Perhaps I am doing the author an injustice; perhaps there is a purpose behind his method. May it be that he wishes to add the last straw and break the back of the hopeless confusion which pervades hæmatological nomenclature. Is it not time that an international effort be made to clear the ground?

I am, Sir, yours faithfully,

Wimpole-steet, W., Feb. 23rd. HUGH S. STANNUS.

THE INJECTION TREATMENT OF VARICOSE VEINS.

To the Editor of THE LANCET.

SIR,—Though altogether out of sympathy with the injection method of treatment of varicose veins, I have been content hitherto to remain silent on the subject, but in view of the annotation on p. 408 of your last issue I feel impelled to do more than merely register a silent dissent from the conclusion there advanced. In this annotation it is assumed that the case for the injection treatment is now proved beyond question, and the reader is left to infer that this point of view is now generally accepted. I quote from the article :—

> This treatment is so simple, so effective, that it has ousted almost completely the treatment by operation. On the whole, it can be said that the injection methods now generally adopted are suitable for routine use. The risk is less than operation and the results are better.

This is a general statement that should hardly be made without a simultaneous presentation of the proofs upon which it is based.

As one who not merely does not believe in the injection method, but, indeed, profoundly disbelieves in it, may I say that I am prepared to accept only one part of the statement—namely, that the treatment is simple. To my mind its simplicity is one of its chief drawbacks, in that it tempts the inefficient and perhaps the less scrupulous members of the profession to carry it out too often without any, or sufficient, justification. I do not admit as proved that the method is as effective as operation in cases that really require treatment. I am not concerned with the other cases that have so enormously swelled the statistics of recent years, cases many of them that required no active treatment. Nor am I prepared to admit that it has yet been decided whether the risk of injection or of operation is the greater.

I am not desirous of initiating a correspondence on the subject, nor am I inclined to take part in any correspondence that may emerge, but in view of your article, and the assumption therein that the matter has been settled now beyond dispute, I feel that it is necessary to make this protest. I profoundly believe, and I am accustomed to teach my students, that the injection method of treatment is unsound scientifically, and therefore unjustifiable surgically. I shall be told that I am not entitled to express an opinion on the subject because I have not personally put the method to the test of trial—which is true. But I reply that I have not put it to the test *because* it is unsound, and therefore surgically unjustifiable. The avowed purpose of the method is the obliteration of the lumen of a vein by the production of thrombosis. It is my considered opinion that the deliberate production of thrombosis by the surgeon—or by anyone—is unjustifiable. Every surgeon knows of the disastrous effects of the thrombosis and embolism which occur occasionally after any surgical procedure. Can it then ever be justifiable deliberately to encourage such a happening?

I shall be told that the type of clot which is sought—and perhaps obtained—in the injection treatment of veins is different, and behaves differently, from the thrombus we fear so much in other conditions. I am not convinced that it is in any essential way different, or can be trusted to behave differently. I shall be told that obliteration of veins produced in this way is an imitation of Nature's method of cure. I am still unconvinced. And even if this be admitted, I would humbly point out that even Nature makes mistakes sometimes. Most of us could cite cases of death following upon simple thrombosis of varicose veins, with resultant embolism, where no operative procedure of any kind had been carried out. I dare to suggest that even now we have not got a full or a true record of the ill-results, and even of the fatalities that have followed upon the injection treatment of veins; but these will yet emerge. Only the other day the public press contained the account of an inquest on a fatal case of the kind, though, of course, the medical evidence made much of the comparative infrequency of such an untoward happening.

But apart altogether from actual fatalities, it is certain that there have been many more failures of cure than are generally admitted, even as there have been very many more cases of sloughing of the skin over the injected veins than the writers on the subject seem to be prepared to confess to. I have myself seen a number of these, and the resultant ulcers are nasty enough, and difficult enough to get to heal. Further, in more than one of these cases which I have seen the injection treatment had been carried out upon veins that called for no such active procedure at all. This supports the view, which I stated earlier, that the numbers of cases submitted to injection have been artificially swollen; that many quite young girls, who might happen to have an odd superficial vein, causing no trouble whatever, but perhaps showing as a bluish streak through the diaphanous silk of the modern female hose, have been able to induce someone to try to remove the offending streak by the medium of injection. Indeed, my suspicion in this direction is more than a suspicion; it is a definite conviction. I have several times been asked myself to do the deed—and have refused. In all probability someone more complaisant came to the rescue.

For these and other reasons, therefore, I wish to make it clear that there are still those—and I am one of them—who regard the injection treatment of varicose veins as an unscientific procedure, and therefore unsurgical—certainly not free from risk. It may not be out of place here to say that the same arguments as I have advanced above against the injection of varicose veins—and other arguments perhaps even more potent—I would put forward in respect of the injection treatment of hæmorrhoids.

I am, Sir, yours faithfully,

ARCHIBALD YOUNG.

The University, Glasgow, Feb. 25th, 1929.

OSTOCOPOS.

To the Editor of THE LANCET.

SIR,—There is a curious word which is found in Theophrastus (*Physica*, 7) as an adjective, *ὀστεοκόπος*, translated in Liddell and Scott as bone "shattering." It occurs in Hippocrates 396, 9, and in Galen as a substantive, which Liddell and Scott translate "a sense of weakness, as if one's bones were giving way." It next appears in Latin under the form "Ostocopos" but only twice, in Serenus Sammonicus, Cap. XLVIII., 892, and in Pelagius Vegetius, *de Arte Veterinaria* III., 10, and it is given in Du Cange's Glossarium ad Scriptores Mediæ et Infimæ Latinæ (Paris, 1688), but it only cites Sammonicus and translates it "Dolorem sentiens in ossibus." Sammonicus, who wrote about A.D. 225 in the reign of Alexander Severus, devotes a whole chapter to it, but his work has never attracted any attention in England though widely known on the continent in the seventeenth and eighteenth centuries.

I think it is clear that he is describing dengue, and this is the only description of that disease in ancient writers. He says: "Sometimes a new cause of sudden pain makes its appearance, of which the origin is quite obscure, and it must be controlled by well-established lines of treatment" . . . . "but if fever with a very high temperature (febres calidæ) waste the tissues, &c.," . . . . and, again (901), "besides which it dries up the excessive chyme in the stomach, which more and more forebodes that the tissues are done for," and he winds up by saying, "but in cases of prolonged fever fresh chicken broths made from an old cock are very useful, being restorative to limbs that show subsultus." The heading of his chapter is "On Sudden Pain and Bone Aching."

We have here a description of an acute and sudden disease of epidemic occurrence (nova causa) in which pain in the bones is the most marked symptom. The gastric symptoms in dengue are well known, "gastric oppression is urgent and vomiting may occur," Sir Patrick Manson in Allbutt's "System of Medicine," II., p. 380. Dengue has been known on the Mediterranean coasts since 1779 when it was first

recognised and must have been long known in Africa as the name is a Swahili word. It is quite possible that the disease was more fatal 1700 years ago than it is now. I am, Sir, yours faithfully,

Forest Row, Sussex, Feb. 20th, 1929. A. MAUDE.

TONSILLECTOMY IN CHRONIC ARTHRITIS.

To the Editor of THE LANCET.

SIR,—I must apologise for causing Dr. Warren Crowe to waste his time. The sentence on which he has based his calculations was never intended for more than a warning against undue enthusiasm. The "7000" was, I regret to say, a figure even more rhetorical than I realised at the time I wrote. It was based roughly on the total admissions to the Royal Bath Hospital for the six years. On the terms of the original foundation the hospital regulations allow for a fortnight's treatment. If a patient's stay is prolonged a "readmission" is recorded. For instance, in 1921 the total "admissions" were 1288; but of these 498 were "readmissions." For 1921, therefore, 730 individuals were treated; about half of these suffered from arthritis. The 7000 consequently falls to the ground—except as a caution against enthusiasm.

But Dr. Crowe refers to 7000 cases of "rheumatic disease"—a term which I suspect of being rather narrower than mine, which included all forms of arthritis, and, in addition, a large number of cases of fibrositis and neuritis. The facts, as near as I can ascertain them, are that during this six-year period 2333 cases of all forms of arthritis were admitted. Of these, 1750 belonged to the infective arthritis group, comprising:—

(*a*) Rheumatic fever and subacute rheumatism .. 245 cases.
(*b*) Specific infective arthritis.
(*c*) Focal arthritis with definite focus .. .. .. } 1470 „
(*d*) Indeterminate: focus unknown .. .. }
(*e*) Zymotic—i.e., scarlet fever, diphtheria, &c.

It is, of course, principally with these that tonsillectomy requires consideration; but, I claim, more consideration than Dr. Crowe is prepared to allow.

I am, Sir, yours faithfully,

Harrogate, Feb. 18th, 1929. A. B. PAVEY-SMITH.

THE LEGAL VALUE OF A MEDICAL REFEREE.

To the Editor of THE LANCET.

SIR,—The Laws of England provide that a judge can demand the services of a medical expert as a referee in cases where medical matters are the predominant features of a trial. As a matter of fact, the Home Office has medical experts whose evidence it calls in cases of suicide and murder. This evidence is indispensable and forms a prominent part of the problem which goes to the jury. It has always seemed to me strange that judges never seek for their personal guidance the services of a medical referee in cases of insanity, malingering, and damages claimed for medical malpraxis. The custom—were it adopted—would in no way detract from the prestige of Law nor of a judge, and it would certainly add to the dignity of his Court. It is not an edifying sight to see opposing medical experts frankly becoming advocates for their respective sides and delaying the proceedings of the Court while coaching their counsels in attempts to trick their opposing colleagues into misleading admissions. The omission to obtain the services of a medical referee sometimes leads to a negation of justice although law may be satisfied. In dealing with trials concerning navigation an expert navigator acts as referee to the judge. The failure of a judge to avail himself of the Law's provision in cases of medical and legal importance cannot be due to his greater knowledge of Medicine than of Navigation. The reason seems to me to be that Law does not yet realise the greatness of Medicine now compared to its position in the past. Other departments of State understand the overwhelming value of this science. There can be no doubt that eventually Law will be compelled to modify its procedure in the direction I have indicated when dealing with cases of combined medical and legal complexity.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 25th. G. LENTHAL CHEATLE.

*** At the Bristol County Court on Feb. 19th medical evidence was heard on both sides in an arbitration under the Workmen's Compensation Act. In delivering judgment, which was limited to a declaration of contingent liability, his Honour Judge Parsons expressed the hope that (if there was a future hearing of the case) he might have the assistance of a medical assessor, as it was difficult for a layman to decide a point upon which medical experts were in conflict.—ED. L.

URÆMIA SIMULATING ACUTE INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—Is there not an error in Dr. Leslie Smith's and Mr. Kenneth Heritage's argument? Discussing their most interesting case of uræmia associated with acute intestinal obstruction, they say: "There is, in this case, no suggestion of mechanical interference with the urinary tract" (THE LANCET, Feb. 23rd, p. 416). I take it they are referring to the urinary tract distal to the kidney; but the question is, where does the urinary tract begin? Does it begin in the calices of the kidneys; or may the Bowman's capsules be legitimately regarded as its beginnings? In the latter case—if the uriniferous tubules may be considered as integral parts of the urinary tract—mechanical interference with parts of the tract in so far from being clearly absent in their case seems to have been clearly present. That at least must be so if the case presented the signs usual of acute intestinal obstruction—increased tonicity of the abdominal wall during the pains, common to all colics, and the marked contractions during the strainings, whether associated with the vomitings or not.

There is a good deal to be said in favour of such a view. The idea is supported by the difficulty of believing that absorption of intestinal contents (putrefactive or not) is a special feature of the obstructed gut—the evidence is that fluid is poured from the gut wall into the lumen of the gut (hence (1) the anhydræmia, and (2) the copious vomitings); and by the difficulty of believing that if intestinal poisons (changed proteins) were absorbed and caused the renal disability, the process of such absorption should so soon cease with the relief of the obstruction, as indicated by the amazingly rapid improvement in the patient's general condition and the (presumably) slower yet "dramatic" fall in blood-urea, the direct consequence of operation. This latter clearly does not suggest a toxin had been in play; on the contrary, it opposes that supposition.

Obstruction to the urinary outflow, whether caused by phimosis, an enlarged prostate, an obstructed ureter, all affect the patient and his blood-urea; nor does the obstruction have to be complete to do so. Thus, a series of compressions of the kidney, if marked enough, may quite reasonably be impugned as causal of renal aberration and to some extent at least of the oliguria (not mentioned in this case). We may perhaps go even further and wonder whether such compressions, as subtle in their play as poisons, under somewhat different physical conditions, may not be causal of that nephrosis so beloved of physicians as patently the product of indefinable and unknown toxins. I am, Sir, yours faithfully,

Rugby, Feb. 23rd. R. H. PARAMORE, F.R.C.S.

SPINAL ANÆSTHESIA IN ABDOMINAL SURGERY.

To the Editor of THE LANCET.

SIR,—Some 12 years ago I urged in your columns [1] the more general adoption of spinal anæsthesia for

[1] THE LANCET, 1916, ii., 645.

acute abdominal cases in patients of all ages, from 6 months to 70 years. It is interesting and pleasing to find this advocacy supported by Mr. McNeill Love last week in his Hunterian lecture. What preparation of stovaine Mr. Love uses he does not say, but with the 10 per cent. solution of stovaine in sodium chloride the head should be lower than the feet as from the time of injection, and a high Trendelenburg position can be adopted immediately. Using the solution named I have never been able to demonstrate that posture has any effect on the level of anæsthesia attained, and clinical findings therefore support Dr. Howard Jones's contention that spread through the cerebro-spinal fluid is by diffusion. In that paper, too, is indicated a technique for the conduct of all operations in which spinal anæsthesia alone is used, including those on the upper abdomen. It is heartening to those of us who have been ardent supporters of spinal anæsthesia for many years to find that Prof. Pannett supports its use and pleads for further consideration of this unjustly maligned method.

I am, Sir, yours faithfully,

PERCIVAL P. COLE.

Harley-street, W., Feb. 25th, 1929.

To the Editor of THE LANCET.

SIR,—I acknowledge my error in supposing that diffusion adds material assistance to gravity in the distribution of novocaine and thank Prof. Pannett for the correction.

I am, Sir, yours faithfully,

W. HOWARD JONES, M.B., B.S. Lond.

London, W., Feb. 26th, 1929.

PROPHYLAXIS OF INFLUENZA.—Dr. A. Graham-Stewart writes that the number of organisms per c.cm. in the vaccine he uses (THE LANCET, Feb. 23rd, p. 415) should have been given in *millions*, not thousands.

Public Health Services.

INFLUENZA.

CLINICAL reports from various parts of England and Wales indicate little change in the position beyond a somewhat more even distribution of the disease. Incidence is still reported high in the north-western area, particularly Manchester and Liverpool, although decrease is admitted in the latter place. Prevalence increases, if not at the previous rate, in London and the home counties. Elsewhere in the country the epidemic is widespread except in South Wales and Bristol, where it appears definitely to have declined. Sheffield, which has hitherto been reported free, is now affected; Nottingham and Stoke-on-Trent, where some incidence was reported at the outset of the epidemic and which were subsequently reported free, are now again stated to be affected. The disease is reported generally to be mild, although otorrhœa is mentioned as a complication in the Manchester district.

On the Continent the epidemic is abating except in certain towns of Western and Southern Germany and some parts of Spain.

THE LOCAL GOVERNMENT (SCOTLAND) BILL.[1]

THE Local Government (Scotland) Bill, having got through the Committee stage in the House of Commons on Feb. 25th, emerges with certain important new features. One of the most interesting new clauses is that which deals with the treatment of the sick and with hospital organisation. For the first time sickness is to be separated from the poor-law and the distinction between poor-law patients and public health patients is to disappear. County and town councils are given the power to submit schemes for reorganising the hospital facilities at their disposal so as to provide treatment for sick persons in their area. These schemes will go to the Department of Health for Scotland (as we must now call what we used to know as the Scottish Board of Health) for approval, the Department being directed to have regard to any other facilities for treatment "including those provided by any voluntary hospital or other institution." Some comment was evoked by the fact that the clause is not mandatory, but permissive. The Government spokesmen explained in reply that elsewhere in the Bill (in what was clause 50) the Secretary of State for Scotland, if satisfied that a council has failed to achieve or maintain a reasonable standard of efficiency in the discharge of its public health functions, can reduce its grant. But this is, of course, neither so peremptory nor so prompt a method. In addition to the submission of schemes as already mentioned, there is power under the new clause for the councils to represent to the Department that their available hospital facilities are inadequate for the reasonable requirements of the area and to submit schemes for extending existing facilities. In that event the Department, before approving such extension schemes, has to be satisfied that the council has taken "reasonable steps to seek and to continue to secure full coöperation with every voluntary hospital, university, or medical school within or serving the area of the council." Where the Department has approved either kind of scheme, the county or town council may accordingly "provide, furnish, and maintain, for the accommodation of sick persons residing within their area, hospitals temporary or permanent and houses of reception for convalescents," and for this purpose may either themselves supply the accommodation, or may contract for the use of it, or agree with the managers of existing accommodation on payment, or utilise any hospital, house, or other buildings already possessed by the council. Another important new clause is that for the recovery of expenses of treatment. Under the old law the poor-law authority could recover expenses if the supposed poor person had some money put away somewhere; it is not unreasonable to put all the hospitals under the new arrangements upon the same basis. There remains presumably an exception for infectious disease since it is usual to remove the infectious case to a special institution under an almost compulsory power for the protection of the community. Objection was raised that demands may be made in maternity cases which may be deterrent to the patient and which are in contrast with the free treatment given for venereal disease. The clause, however, got its second reading without a division and was not altered in Committee.

The general position of the proposed reform of Scottish local government may be summarised as follows: The original idea was to abolish the parish councils and transfer their functions to the bigger reconstituted authorities. As in the English parallel, there was naturally an objection that the great merit of the parish councils was the maintenance of local touch in administration. The Government then brought in a new clause to set up district committees for landward county areas. The new district councils will contain the local county councillors and other elected representatives of the local area. The new county councils will be allowed to delegate certain functions under approved schemes; it will be interesting to see where outdoor and indoor relief administration will respectively be allocated in consequence. There will naturally be much sentimental regret at the disappearance of the old parish councils in Scotland, bodies very different from the parish councils in England. There is gradually being evolved a new system of local government for both countries on

[1] The discussion on the Bill in Committee of the House of Commons is reported in our Parliamentary columns.—ED. L.

roughly parallel lines. On the whole the reception of the Scottish proposals by those from whom criticism was expected seems by no means unfavourable.

MENTAL HOSPITAL REPORTS.

SOME SCOTTISH HOSPITALS.

WE welcome the appearance of the reports of the *Crichton Royal Institution, Dumfries*, and the *Glengall Hospital*, at *Ayr*, for the full year 1928. They are the first of their kind to reach us, commendably early in 1929. On Dec. 31st last there were 1043 patients in the Crichton Hospital, an increase of 53 during the year. Of these, 297 were on a voluntary basis. There were 106 more patients admitted during the year than the average number, so the staff had a busy time. During the year 459 voluntary patients were under treatment, and only two of them had to be certified. The increase in the number of voluntary boarders was especially marked among private patients. The majority were middle-aged people who had not previously had a mental breakdown. The recovery-rate was 25·5 per cent. of the voluntary and 23·5 per cent. of the certificated cases. The death-rate was 7·3 per cent., and the general health was satisfactory, except for three cases of scarlatina among the nursing staff. A new reception hospital was opened in November, and in May an arts and crafts pavilion was inaugurated to expand and improve previous arrangements for occupational therapy. An occupational instructress has been appointed, in addition to the supervisor of outdoor occupations and recreations, who has been at work for ten years. The grounds supplied the institution with vegetables, fruit, and flowers, and the farm had a successful year. One hundred patients had parole outside the grounds, and just over a hundred within them. The famous rock garden, laid out four years ago, already contains more than 2000 named specimens. Twenty-two nurses and five attendants obtained their M.P.A. certificate during the year, four with distinction.

The Glengall Hospital at Ayr had 605 patients on its books at the end of the year, 12 of these being on a voluntary basis. More than a quarter of those admitted were in a precarious state of health physically. That the type of case sent to the hospital has greatly deteriorated since the war is proved by the fact that, in spite of a comparable average admission rate, the average death-rate, which was 36 per cent. from 1909–13, has risen to 55 per cent. between 1924 and 1928. This means a lower recovery-rate and greatly increased work for the nursing staff. The recovery-rate for the year was 31·5 per cent. and the death-rate 15·7 per cent.—the highest on record. Procrastination in seeking treatment is declared by the medical superintendent to be largely responsible for the increase. General paralysis heads the list of causes of death despite modern methods of treatment, and there were 12 deaths from tuberculosis. Autopsies were held on 88 per cent. of cases. Apart from debility, the general health was good. Occupational therapy has been initiated, and—apart from bedridden patients—only 36 patients were unoccupied at the time of the Commissioner's visit. Their work was chiefly in the grounds or laundry, but a certain number assist the artizans in the workshops. Arrangements are at last to be made for dental care. The hospital now has 48 per cent. of its staff fully trained and certificated, four nurses and five attendants having obtained their M.P.A. certificate during the year.

The report of the *Stirling District Board of Control* for 1927–28 shows that on May 14th last there were 943 certified and 25 voluntary patients in the mental hospital at *Larbert*, an increase of 59 during the year. In addition, there are 88 patients in the lunatic wards of poorhouses, 83 boarded-out cases, and 155 mental defectives. The committee notes that, since the hospital was opened in 1869, over £200,000 have been spent on it. The capital expenditure was met by mortgages, and the assets vested in the district board now greatly exceed the balance of mortgages still outstanding. Of the 23 voluntary patients admitted during the year, 13 were chargeable to parish councils, reminding us again of the advantage Scotland has over England in the treatment of early mental disorder among the poorer classes. The recovery-rate was 37·35 per cent.; 49 patients were discharged recovered within six months of their admission, and one case of melancholia left recovered after eight years; 16 patients were sent out on trial, and only one had to return. The death-rate was 8·2 per cent., and the cause of death was verified by autopsy whenever permission could be obtained. Except for mild influenza, the general health was satisfactory. Electrical and ultra-violet ray treatment have proved beneficial for many patients, and the X ray apparatus was used diagnostically in 33 cases. The health of a large number has shown improvement as a result of the systematic attention given to their mouths and teeth by the dental surgeon, who visits weekly. During the year he extracted 1036 teeth and filled 120 more. Only eight patients had healthy mouths, and very many had acute gingivitis. The occupation department employs a great number in various handicrafts, and special attention is paid to those whose symptoms and habits preclude other forms of employment. Others have worked in the grounds, which supply the institution with flowers and vegetables. The wet, dull weather spoilt the year for the farm, but the crops were secured in fair condition. Sixteen nurses and 11 attendants obtained their certificate during the year, bringing the total to 45.

On May 16th, 1928, there were 729 persons in the *Inverness District Asylum*, the steady increase of the last four years being maintained. The increase in population is not due to an increase in the admissions but to the large proportion of incurable permanent cases. This has meant considerable difficulty in finding suitable accommodation; no less than 47 of the women are more than 70 years old and in need of constant nursing care. The recovery-rate of 34·8 per cent. is therefore a high one. Nineteen patients went out on probation during the year, of whom one returned. The death-rate of 7·8 per cent. is a great improvement on last year. Phthisis and senile decay were responsible for half the deaths. Twelve autopsies were held. The nine patients suffering from phthisis are nursed in the open air. The grounds and buildings gave employment to 446 patients, but there is no occupational therapy department. Apart from a shortage of milk, the supply of farm produce was very satisfactory. Eight nurses and four attendants obtained their M.P.A. certificate. The report includes an interesting summary of the structural history of the asylum since 1864, and a list of the certificated nurses. There must be very few institutions that still retain the name "asylum," which has unfortunately acquired an evil connotation in the public mind.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 16TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 231; scarlet fever, 1966; diphtheria, 1169; enteric fever, 37; pneumonia, 3658 (last week 3898); puerperal fever, 41; puerperal pyrexia, 99; cerebro-spinal fever, 19; acute poliomyelitis, 4; acute polio-encephalitis, 2; encephalitis lethargica, 25; dysentery 2; ophthalmia neonatorum, 108. No case of cholera, plague, or typhus fever was notified during the week.

Counties reporting large numbers of cases of pneumonia are as follows: London, 562 (last week 689); Chester, 173 (172); Durham, 168 (133); Essex, 167 (136); Lancaster, 906 (1102); Stafford, 113 (153); Warwick, 131 (132); Yorks West Riding, 296 (292)—from which it will be seen that the incidence generally is on the down-grade.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Feb. 19th–20th was as follows: Small-pox, 39 under treatment, 6 under observation; scarlet fever, 1815; diphtheria, 2000; measles, 51; whooping-cough, 932; puerperal fever, 18 (plus 4 babies); encephalitis lethargica, 80; poliomyelitis, 5; "other diseases," 60. At St. Margaret's Hospital there were 10 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 77 (0) from measles, 9 (1) from scarlet fever, 229 (80) from whooping-cough, 48 (8) from diphtheria, 48 (10) from diarrhœa and enteritis under two years, and 1243 (393) from influenza. The figures in parentheses are those for London itself.

The number of deaths from influenza during the previous eight weeks was 69, 83, 99, 122, 179, 321, 652, and 987 respectively, the figures for London during the same period being 9, 15, 18, 34, 39, 77, 198, and 331, from which it is seen that the rate of rise has moderated in London as elsewhere. In the week under review deaths were attributed to influenza: Manchester, 119; Leeds, 56; Liverpool, 46; Salford, 34; West Ham, 33; Middlesbrough, 31; Birmingham, 29; Bolton, 25; St. Helens, 20; Stoke-on-Trent, 19; Oldham, 18; Norwich and Croydon, each 17; Portsmouth, 16; Ealing and Leicester, each 14; Walthamstow and Stockport, each 12; Birkenhead, 11. No other great town had as many as 10. (Glasgow reported only 33, Edinburgh 68, and Belfast 41.) Liverpool reported 21 deaths from measles, Sunderland and Cardiff each 9. Deaths from whooping-cough were reported from Manchester, 23; Salford, 14; West Ham, 11; no other large town more than 10, but the deaths were widely distributed.

The number of stillbirths registered during the week was 314 (corresponding to a rate of 54 per 1000 births), including 52 in London.

Death-rates from Influenza for the Last Quarter.

The death-rate from influenza in the different parts of the country is set out by the Registrar-General in a comparative table of figures since December, 1928.

* Excluding Greater London.

The figure is the number of people per 1000 of population who would die in a year if the death-rate of the week in question were to persist for that period.

DONATIONS AND BEQUESTS.—Mr. Edwin Norton, Great Central Hotel, Marylebone, London, and formerly of Mansfield, Weybridge, left £2000 to St. John's Institution for the Deaf and Dumb, Boston Spa.—Mrs. Eliza Jane Briggs, Bowdon, Cheshire, widow of Thomas Briggs, an ex-Lord Mayor of Manchester, left about £30,000 to Manchester Charities, including, among other bequests, £2500 to the Manchester Royal Infirmary, £2000 to the Altrincham General Infirmary, £1000 each to the Manchester and Salford Hospital for Skin Diseases, and to St. Mary's Hospital for Women and Children, Manchester; £500 each to the Manchester Children's Hospital, Pendlebury; Henshaw's Blind Asylum; the Northern Counties Hospital for Incurables, the Adult Deaf and Dumb Institution, Chorlton-cum-Hardlock, and the Manchester and Salford Branch of the Society for the Prevention of Cruelty to Children. The residue of the property, about £16,000, goes to the East Lancashire Home for Disabled Sailors and Soldiers, Park-lane, Broughton.—Mrs. Lucy Greene, of Bydinghurst, Cranleigh, left large bequests for charitable purposes, including £8000 to the Lebanon Hospital for the Insane, £5000 to the National Society for Epileptics, Chalfont St. Peter, and £500 to St. Dunstan's Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT (SCOTLAND) BILL.

THE House of Commons went into Committee on the Local Government (Scotland) Bill on Wednesday, Feb. 20th. Mr. J. F. HOPE, Chairman of Committees, was in the chair.

Failure to Discharge Functions.

On Clause 25 Major ELLIOT (Under Secretary of State for Scotland) explained that the clause provided that where the Scottish Department of Health were satisfied after a local inquiry that a town council of a small burgh had failed to discharge their functions with respect to the provision of water-supply, drainage, or housing, the Department might authorise another authority, such as the county council, to discharge those duties. It was, however, only reasonable that this overriding power should apply both ways, and he therefore moved an amendment providing that if a county council were in default the particular duties in that area should be taken over by another authority—possibly the burgh authority.

Mr. STEPHEN moved an amendment to the amendment making it mandatory on the Department of Health to order in the case of default by one authority that the duties should be undertaken by another body.

Mr. WATSON (Lord Advocate) opposed the amendment. The view of the Government was that there might be cases where the local authority might be justified in maintaining for a time that there was no failure on their part. An inquiry might substantiate a different view taken by the Department. It would be a wise arrangement that the Department should be enabled in such circumstances to give the defaulting body time to put the matter right.

The amendment to the amendment was rejected by 196 votes to 86.

On Clause 26 (the county medical officer of health and the sanitary inspector to act for small burghs),

Mr. W. ADAMSON moved an amendment to provide for the continuance of

Whole-time Sanitary Inspectors for Small Burghs.

He said if the control of this work passed into the hands of the county councils a county council might appoint a sanitary inspector for the whole of the county. That would be a retrograde step and might have serious consequences. He knew a number of small burghs where there was plenty of work for a full-time sanitary inspector if the health of the people was to be properly attended to.

Sir R. HORNE said that he agreed that it might be a proper thing for a medical officer of health of a burgh to be the county medical officer of health also, because the latter was an appointment with wide ramifications and a medical officer employed a large number of people under his guidance to deal with questions of health in the county. But when they came to the question of sanitation in any particular district it seemed to him that they were dealing with a business which was purely local. When they considered the sanitation of a small burgh there was obviously enough work for any one man to do. He therefore thought that the question of sanitary inspection should be excluded from the clause.

Sir R. HUTCHISON, in supporting the amendment, said they were looking forward to better sanitary conditions in Scotland. The well-being of the burghs, especially the industrial burghs, depended very largely on the supervision and activity of the sanitary inspector in pointing out defects and preparing the way for improvement.

Major ELLIOT asked the Committee to consider the actual figures. Of 179 small burghs in Scotland 26 had appointed the county officer to act for them, 106 had full-time officers, and 47 had part-time sanitary inspectors. He asked hon. Members, and particularly his medical colleagues in the House, to consider the position of a sanitary inspector. That position was growing more difficult than it was a few years ago. It was becoming a more and more technical and highly skilled appointment. It was of great importance to get whole-time skilled men into these important posts. Some of the correspondence which the Board of Health had had in recent years showed that some of the smaller burghs did not by any means rise to the modern conception of good sanitation. They had done their utmost for years to raise the status of the sanitary officer and to make it clear that the position was not less important, but in some ways more important, than that of the medical officer of health. They had done their utmost to secure that the officers appointed should be holders of the sanitary inspector's certificate of the Royal Sanitary Association of Scotland. These were posts which it was much more suitable to be held by whole-time officers, but they found that in practice the

appointments had not been whole-time appointments. He urged the Committee to address itself to the important matter of public health and not to be deterred by the question of the prestige of this or that local authority. There would be no disturbance of existing appointments and nothing would happen until one of the appointments became vacant, when in the view of the Government it ought to be filled by a man of high qualifications who would devote his whole time to the work.

Mr. JOHNSTON said the Under Secretary continually proceeded on the assumption that the initiation, control, and administration of public health in the small burghs was not so efficient as in the counties. Where did he get warrant for that? It was not in the public health statistics nor in the death-rate. They had a lower infantile mortality in the small burghs than in the counties. It was only when they got to the higher ages that there was a lower death-rate in the counties; yet the counties ought to be healthier than the burghs. He had spent many years on all forms of local government in Scotland, and he believed that the step proposed in the Bill was a retrograde one in regard to public health. He would give one illustration. Two years ago in many parts of the country the control of milk and dairies was taken away from the small burghs and handed over to the counties. When the burghs did the work inspections were held at least four times a year. Now under the county councils at most inspection took place twice and in some places only once a year.

Captain FANSHAWE supported the amendment. For the present at any rate they should leave the sanitary inspectors of the small burghs under the entire control of those people who had been elected to look after the affairs of those burghs.

Mr. WATSON (Lord Advocate) said that the desire of the Government was entirely for the improvement of the health of the people and of the sanitary administration of these districts. They did not wish to throw any aspersion on the many admirable instances of burghs which were working satisfactorily at present. He was perfectly willing if the amendment was not pressed at this stage to reconsider the question in the light of the debate which had taken place.

Dr. DRUMMOND SHIELS said that the form of the amendment showed that it was not put forward in any obstructive way. The question of the appointment of the medical officers of health had not been traversed at all, although they realised that many burghs in Scotland would be reluctant to depart from the system of having their own medical officers and undoubtedly many of those officers had done and were doing excellent work. Undoubtedly it was the modern trend in public health to have larger administrative areas for the medical officers of health. But as regarded sanitary inspectors the position was quite different. He agreed with Major Elliot that a sanitary inspector with a multiplicity of posts was not desirable. In some of the smaller burghs where that was the position no doubt the work could be more suitably done by the county officer. On the other hand, it was ridiculous to say that other burghs had not sufficient work to occupy a full-time and highly-qualified officer. He suggested that in reconsidering the matter the Government should take into account the question of whether at least burghs with a population of 10,000 and over should not be allowed to retain the privilege which they now had of appointing their own official to look after their own sanitary requirements.

Mr. W. GRAHAM suggested that the Government would do much better to agree to the amendment and not leave the matter to be discussed on the Report stage which might under the operation of the guillotine resolution be impossible.

Mr. WATSON said that the Government were willing not to oppose the amendment at this stage on the understanding that there would be no breach of faith if it was found necessary to reverse the decision later on.

The amendment was agreed to on this understanding.

Freedom of Choice.

Sir R. HAMILTON moved the first of two amendments which were designed to leave freedom of choice to the burgh in the appointment of a medical officer of health.

Major ELLIOT said that the majority of Members on both sides of the House were agreed that these appointments should follow the course laid down in the clause. It was following out the practice of tradition and the development of public health work in Scotland. It had been done in over 100 cases. It would be an unworkable and retrograde step to accept the amendment.

Dr. SHIELS said that he regretted that he could not support the amendment as he sympathised a good deal with the enthusiasm and the spirit which was expressed by those who supported it. The amendment, however, was not practicable and would not work. If a medical officer was appointed for a county and individual burghs were to have a right to refuse his services and to make another appointment the very greatest difficulties would arise. The burghs which objected might not be the most suitable ones to have a medical officer of their own. They saw with regret the passing of the medical officer of health of the smaller burghs because he had been a local figure of great importance and interest, and in many cases these men had done magnificent work. But they must face the fact that, with the advance of medical science, in order to deal properly with public health matters they must have such laboratory and scientific equipment as the small unit was really unable to furnish. In the interests of the people themselves in the smaller burghs it was important that they should have available the very latest resources of science in medicine and the full equipment associated with these. The Board of Health in Scotland had always in medical matters been up to date and progressive. They would not, he was sure, be averse from taking advantage of the reservation in the clause allowing for a burgh medical officer of health where it was appropriate that a burgh should have a medical officer of its own.

The amendment was rejected by 233 to 43.

On Thursday, Feb. 21st, the House again went into Committee on the Bill with Mr. HOPE in the chair.

Discontinuance of Grants.

On Clause 37 Mr. E. BROWN moved an amendment with the object of excluding from the operation of the block grant system the health services and road grants. He said that there was no single issue raised in the Bill which was raising more disquietude in the country than the change over as regarded health services to the block system. He proposed to leave out from the block system the maternity and child welfare grant for Scotland, amounting to £157,000, the grant for tubercular treatment, amounting to £347,000, the grant for venereal disease treatment, amounting to £66,000, the grant for the welfare of the blind, amounting to £20,000, and the mental deficiency grant of £76,000, making a total of £667,000 with the road grant amounting to £280,000. The Government had already decided that the Government's plan for merging all the public health services under one control in order that they might obtain team work against disease or in maternity would be hampered by the application of the block system to those services. The Government would find that it would be hard to shake that view. The proposal of the Government was that in place of the percentage arrangement previously in operation there should be a fixed sum to be included in the general grant. That sum would have no relation to the actual expenditure on any one of these particular services. Further, that sum would be fixed once and for all on the moneys expended in the standard year. That was one of the worst elements in the proposal. Let them put it as high as they could and grant that this was a great idealistic conception—which he believed it was—in order more fully to organise the medical services and enable more whole-time medical officers of health to be appointed because of the wider area and the greater concentration of the services. How foolish it was then to risk the efficiency of their new organisation by departing from the system of grants which by general consent had worked in the direction of increasing and developing the services. The worst effect of the application of the new system would be that, so far from drawing together all those who were in favour of the expansion of the health services as a band of brothers who desired to help each other in the great work of preventive medicine, it would set up a competition among idealists which would mean that one would want more money for tuberculosis treatment, another for maternity and child welfare, and another for the treatment of venereal disease, and it would leave local authorities with a very grave burden, or change of burdens and with the temptation that these moneys might be used for other local needs. He believed that such a system would hamstring the Government's own scheme for the concentration and better working of the medical services.

Major ELLIOT said that Mr. Brown had undoubtedly raised one of the major issues of the whole Bill. It was not a party issue, but was one which would confront governments of successive complexions for many years to come. Fiscal problems were undoubtedly going to be more and more important as time went on. The system of assigned revenues had been tried and had obviously broken down because of the delocalisation of finance. In the modern industrial State with the local revenues derived from rates one particular place it was no longer possible to apply that system. They all agreed that the Exchequer, the great financial engine of the State, must be brought into play to raise a great portion of the revenues which the local authorities were to expend. The scheme of the Government in this instance was not a stereotyped grant, but was subject to the revision of experience. They had adopted the method of a grant based first of all on compensation, secondly a weighted population, a very important factor, thirdly a permanent increase in the rateable value for every

area in the country and in addition a substantial sum of new money. Further than that there was a guarantee of an increase in successive periods if and when local expenditure increased. This sum was now to be revised in a three-year period. Mr. Brown could not seriously ask them to believe that within a three-year period not only would the whole of the new money have been eaten up, but that the local authorities would be pushed so far against their financial limitations that it would cramp and cripple the new social services which they were anxious to expand. He claimed that the Government's proposal in regard to the health services was reasonable for this reason. The principle of percentage grants had worked in many cases satisfactorily, but in other cases it had not done so. There were large areas to-day which had no child welfare schemes at all. The Central Department had no power at present to enforce schemes and the local authorities had no money with which to put schemes into operation. The Highland counties would receive a sum of over £80,000 a year under this proposal and the Government would have power to call for the institution of such services. The scheme provided the cash and the necessary compulsion, but he did not believe that compulsion would be necessary. Local authorities in the past had not hesitated to develop their health services under the poor-law, even though those services were not attracting Government grants. From his experience he had learned that the long-continued and developed health policies of the great health authorities were not deflected one way or the other by the casual offer or even the continuing offer of a percentage grant. They depended on far more stable and permanent things—on the health conscience of the community, on the will of the electorate, on the enlightened health administration of the local authorities, and those authorities ought to be left as free as possible vis-à-vis the central authority. The central authority should do its utmost, as would be the case under this Bill, to see that the local authority covered a sufficient area and had sufficient resources to plan and develop such policies. In the past they had found this problem a most difficult and intractable one. He did not pretend that this solution was perfect, or that it would not need to be revised, but he contended that it laid down broad general lines upon which national and local development could take place.

Mr. W. GRAHAM said that no Royal Commission or other body which had examined this problem had recommended the scheme which the Government now proposed to apply to Scotland. If they were in fact providing for expansion in vital public health services why not leave the percentage grant system alone? It would give true expansion and they could make it more efficient. If the Government passed this clause in the years ahead it would be revised, altered, and probably abolished.

Mr. JAMES STEWART said he hoped that even at this late hour the Government would consider doing away with the block grant so far as maternity and child welfare was concerned.

Dr. SHIELS said that a very simple test in this matter was to ask whether the first impulse for a change came from the medical authorities in the public service or from the finance department of the public service. He thought that no medical authority would have pleaded for a change from the percentage to the block grant system. The change in the system with regard to public health had quite obviously been made because those services were the fast developing services. In many cases they had doubled and trebled in amount since they were instituted. The harm that would be done by the block system had no doubt been modified by the substitution of three years for five years as the period before the first revision. That would enable adjustments to be made, but even that modification had only been granted after very strong pressure by the local authorities. He was particularly interested in maternity and child welfare, and there was a very special case for those services being favourably considered. Very great and general public interest had been aroused in the question of maternal mortality. It was not easy to allocate the causes of that mortality, but one thing had been definitely settled, and that was that antenatal supervision of the mother did very definitely lessen the maternal death-rate. An adequate antenatal service in every centre of population was absolutely necessary. In Edinburgh, Glasgow, and other cities there was a fairly good service, but even in those centres the number was not sufficient, while the accommodation and comfort of them was very far from being what it should be. In other places things were worse. He wanted these places to be such that women would go willingly to receive the treatment and attention that would mean so much to them at a later date. The last few years had been economy years for the public health committees of the town and county councils of Scotland. In Edinburgh they had been contemplating a scheme for debilitated children which was to cost about £25,000. He understood that it was very uncertain now whether that would go on, because obviously this last had been the standard year, and any expenditure over and above that standard year for the next three years would fall on the ratepayers. The new money was not likely to be nearly adequate to meet the developments that would normally have taken place under the percentage system. Though tuberculosis was not assuming the proportions which it once did it was still a very serious scourge, and there were by no means too many beds available in Scotland for patients. There were in the slums and tenements far too many consumptive people who were a danger not only to themselves, but to the whole community. The treatment of venereal disease was specially endangered under this block grant. It was an unpopular service and one which got previously 75 per cent. from the State instead of 50 per cent. Therefore the local authorities would now have to find 100 per cent. instead of only 25 per cent. The blind were at present a very neglected section of the community. They were fearful, and he thought rightly so, that under this new arrangement they would have rather cursory treatment from some of the local authorities. The mental defectives service was one in regard to which they needed a very great advance. Anything based on the standard year would be obviously inadequate. It seemed to him that they had never yet realised the stupidity of educating these defective children up to the age of 16 and then throwing them out into the world a danger to themselves and to the community just at a time when they need most attention. He felt that on the basis of the standard year any advance in the treatment of mental defectives was unlikely to accrue. There was no place in Scotland where the health services, however good they were, were completely adequate to the needs of the community. The public conscience was more alive than it used to be in regard to health matters, and there was not only a great need, but also a great demand for these public health services which ought to go on and develop. It seemed to him that the argument of Major Elliot that the poor-law health system, in spite of lack of grants, had developed to a high state of efficiency, was not one that could be justified looking at Scotland generally. If the Government were really unable to accept this amendment he pleaded very strongly that at least they should make one exception and remove the maternity and child welfare services from the operation of the block grant.

After further debate,

The amendment was negatived by 174 votes to 102.

Dr. SHIELS moved an amendment to exempt maternity and child welfare from the clause.

The amendment was negatived by 181 votes to 106.

On Friday, Feb. 22nd, the House again went into Committee on the Bill. Mr. D. HERBERT was in the chair.

Contributions to Voluntary Associations in Respect of the Welfare of the Blind and Mental Defectives.

On Clause 48 Dr. SHIELS moved the following new subsection:—

"The Central Department may, before the beginning of each fixed grant period, make a scheme providing for the payment by county councils and town councils of large burghs specified in the scheme of such amount as may be specified in the scheme to the central council or committee of an approved organisation which provides services in the nature of general publicity, and educational propaganda in furtherance of the prevention and treatment of venereal diseases."

He said that the amendment was to add to the possible schemes already indicated in the clause one in regard to venereal disease. Those who were interested in public health were a little apprehensive as to the effect of this Bill on many health services and specially venereal disease. The proposal to drop the grants which had previously been given for propaganda was very unwise. Last year the House decided that the voluntary system was sufficient. His own feeling was that a purely voluntary system would not be effective in stamping out the disease, but however that might be, all who understood the subject were agreed that the voluntary system could not succeed unless the public generally understood and realised the seriousness of these conditions. A great deal of the work in hospitals was really in origin related to this subject. A similar amendment was put forward in connexion with the English Bill, but the Minister of Health did not find himself able to accept it. A very important alteration had been made in the present amendment by substituting the word "may" for the word "shall." It would now be within the discretion of the Minister to make such a scheme if the attendance at the clinics or the number of defaulters was such as to make it in his opinion desirable. A committee in Scotland had been carrying on this propaganda since 1921. It was a committee of the British Social Hygiene Council. The committee had been carrying on very important work by lectures, advertising and distributing literature, particularly in those areas where there had been a lack of interest and where cases were not coming forward to the clinics. The

Scottish Board of Health had been in the habit of giving a grant of £1000 a year for the work, and in view of the statements that were sometimes made as to the value or otherwise of propaganda he would quote the following passage from the Report of the Scottish Board of Health for 1927 :—

"Propagandist and Educational work.—The former of these provisions the Board has left in the hands of the Scottish Committee of the British Social Hygiene Council, being well assured that that body could and would do the work as well as it was possible for it to be done, and content, therefore, to stand by approvingly and render the necessary financial aid. That the work of the Scottish Committee has been effective and of high value is certain, but we learn from time to time with some surprise that information regarding these ailments, their nature and treatment, and regarding the existence of clinics where efficient and confidential treatment is available without charge to all, and, at least to the great majority of city and town dwellers, reasonably acceptable—that this information, actively disseminated as it has been for six or seven years, has not as yet by any means found its way to the whole of the population. At the male venereal disease clinics it is no uncommon experience to hear, in answer to the medical officer's question, 'Why did you not come here sooner?' the remarkable reply, 'I did not know that there was such a place.' In the female clinics such an assertion of ignorance is still more frequent; and at the latter, in addition, there is often revealed an almost incredible ignorance with regard to the manifestations of one or other of the maladies in question, or even as to the nature and significance of general indications of ill-health."

He felt that this work was national and should be done by a national department, but as the Government were not likely to agree to that he suggested that this voluntary body composed of many able and well-informed people which had been doing such effective work should be allowed to carry on, or else that some similar body should have the task of enlightening the public as to the great importance of these diseases. Those who were in charge of the treatment of venereal disease in Scotland were satisfied that if things were left as they were in the Bill local authorities would not voluntarily contribute to the funds of such an association. He hoped, therefore, that the Government would consent, especially having regard to the optional nature of the amendment, to ensure a continuance of the system which had secured at least an effective method of disseminating information regarding these diseases throughout Scotland.

Major ELLIOT said that he had done his best to address himself to the amendment from a non-party point of view, because there was undoubtedly much to be said for the arguments which had been advanced that the propaganda with regard to this disease was of vital importance and that in many ways it was better exercised from a central than from a local body. There were, he thought, conclusive difficulties against adopting the course of compelling local authorities to contribute towards the funds of voluntary associations. But the very fact that local authorities had sympathetically approached himself and other members showed that there was a feeling of full responsibility among health authorities as to their duties in connexion with propaganda work. There was a great danger in specialising one or two activities or a group of activities concerning which the local authorities must make payments. He thought that the matter would be much more readily met by a method which he would propose to the Committee. It was that in the first place the present grant from the central authority to this voluntary society should be continued. That would run up to May, 1930. He was prepared to recommend that a substantial additional sum should also be obtained from the Treasury—and he did not doubt that he would be able to obtain it—towards the expenses of this voluntary society. That would give a considerable time for those concerned to look round. He was also prepared to say that he would call a meeting of the local authorities particularly concerned in the matter and discuss the subject frankly with them. He had no doubt that they would be able to come to an agreement with the local authorities as to the health propaganda work which they desired to carry on. He did not desire to impose on the central department further powers to compel local authorities by fiat to expend sums out of money which they rightly regarded as their own money and their own responsibility. The position of the society would be safeguarded for this year and during that time the local authorities would have considered the position in regard to health propaganda and publicity.

After further debate,

Major ELLIOT said that he would undertake to convey the views expressed by hon. Members to the Secretary of State for Scotland, but he could give no pledge. He would discuss with his right hon. friend the general question of health propaganda. It must be clearly understood that they were not suggesting any payment or guarantee of payment to any single voluntary organisation or in respect to any particular disease barring the additional sum which he had already mentioned—namely, the sum in consideration of the change in the operation of the grant which was now taking place.

Dr. SHIELS said that he thought they could discern in Major Elliot's speech at any rate a sympathy with the objects of the amendment. He would therefore ask leave to withdraw his amendment.

The amendment was by leave withdrawn.

On Monday, Feb. 25th, the House again went into Committee on the Bill, with Mr. DENNIS HERBERT in the chair.

Reorganisation Schemes.

Mr. MACROBERT (Solicitor-General for Scotland) moved a new clause to enable local authorities to submit schemes for reorganisation with a view of removing the distinctions between poor-law patients and the public health patients, and to provide for hospital treatment under the public health authorities and not under the poor-law. He said that in the clause there were safeguards with regard to the voluntary hospitals, and one of the objects of the clause was to secure coöperation between the public authorities, the voluntary hospitals, and the medical schools. The schemes for reorganisation had to be submitted to the Secretary of State for Scotland by the various authorities, either county council or borough council. A wider definition was given of the words "hospital facilities." Power was given to the authorities to spend money in extensions where the present facilities were inadequate. The department would satisfy itself with regard to an appropriate scheme by inquiry, not necessarily by a formal or local inquiry. In the event of a scheme not being approved in terms by the department they might modify or amend it. Statutory powers were given to the authorities in connexion with general hospital services. At present they only had statutory powers in regard to hospitals for infectious diseases. The statutory powers were to extend to general hospital facilities in the same way that they now extended to the infectious diseases hospitals. Authorities were given power to give hospital services for people living in another area.

Mr. STEWART urged that it should be made obligatory on every county council and town council to prepare a scheme for the consideration of the central department.

Lieut.-Colonel MOORE said he represented some of the most progressive seaside towns in Scotland. In the arrangements made for a very large summer population hospital accommodation was very prominent. In certain cases the town councils had established very fine hospitals for fever and other cases and out of the rates they had practically paid off the entire capital cost incurred in building and equipping the hospitals. Under this new clause these hospitals would be taken over by the new county authorities and as far as he could see no question of compensation arose.

The CHAIRMAN pointed out that Colonel Moore could not raise that question at that point, as it came under Clause 6.

Colonel MOORE said that in that case he would ask the Government to bear in mind that there was a feeling that these towns should be compensated for the capital expenditure which they had incurred in respect of their hospitals.

The Labour View.

Dr. SHIELS said that the Labour Party agreed with the main principles of the clause, but there were certain features which they would like to see altered. In the larger industrial districts in Scotland and England hospital arrangements were in a more or less chaotic condition. Reorganisation in these cases was absolutely essential if the full facilities available in the public and voluntary hospitals were to be utilised. If the clause was to be permissive they would still be left in the same old position with regard to reactionary or lazy authorities. One of the hopeful features of the section dealing with the extension of hospital facilities was that it provided some remedy for the serious condition of the voluntary hospitals as regarded their accommodation. The Mackenzie Commission which reported in December, 1925, gave the total number of voluntary hospital beds in Scotland as 8589. There had probably been an increase since that time, but they estimated that 3600 additional beds were immediately needed in order to provide the necessary accommodation. The Edinburgh Royal Infirmary had a waiting list of over 2000 people, many of them being surgical and medical cases, including cancer cases. The same was true in regard to Glasgow and indeed the voluntary hospitals of Scotland did not provide except very partially for the needs of the community. In the poor-law hospitals and sick wards of poor houses there were 6100 beds. Of that number 4285 were grouped in the larger poor-law hospitals. One effect of this new clause would be that in those cases where the poor-law beds were not fully occupied they would be available to the local authority to meet the needs of the sick people in the district. It was surely even more necessary that immediate steps should be taken, seeing that there were these facilities, to prepare a scheme, not only for coördination, but for making the necessary additions and extensions in areas which quite evidently required it. In regard to the inquiry mentioned by the Solicitor-General

he wished to know whether it was to be a public inquiry with witnesses; whether it was likely to be expensive, with counsel representing the various conflicting authorities; and whether people with vested interests would be able to object to the necessary extensions and either defeat the object of the local authority or add considerably to its expenses in establishing approval of the proposed scheme.

After further debate,

The Lord Advocate's Reply.

The LORD ADVOCATE said that the Government felt that it would be a bit hard and unwise to make the preparation of schemes mandatory in the way which had been suggested. But he would point out that under Clause 50 every local authority was bound to exercise its functions up to a certain standard and to provide adequately for the health of the people in the district. The word "function" was defined as including not only duties, but powers, and as a lawyer he said that the power which was conferred on local authorities in this clause was one which they would be bound to exercise; otherwise their grant would be reduced.

The clause was read a second time and added to the Bill.

Recovery of Expenses for Treatment of the Sick.

The LORD ADVOCATE moved a new clause dealing with the recovery of expenses in connexion with the treatment of the sick. He said that at present the poor-law authority had power to recover expenses for the treatment of poor persons from those who were legally liable for the maintenance of those persons, and it was now proposed that all the hospitals under the new sick persons scheme should be put more or less on the same basis. The poor-law power, of course, would remain with the new body. There was an exception in the case of infectious disease and the reason for that was obvious. According to the customary practice infectious patients were compulsorily removed for the benefit of the community at large, and that made all the difference. The amount to be recovered was limited to a reasonable amount.

Dr. SHIELS said that he was glad that the Government had now amended this clause in accordance with suggestions made by the Opposition and to that extent he thought it was a great improvement on the original drafting. The use of the word "reasonable" was a great improvement. But he protested against the distinction still drawn between infectious and other diseases. He would like to say something about the maternity hospitals. A great deal was being done in regard to the reduction of maternal mortality, and one proposal which seemed likely to be fruitful was that instead of one big maternity hospital there should be a number of smaller hospitals in different parts of the town or the county where patients could be more readily and quickly attended and where a certain amount of isolation could be secured in cases where there was an infective condition. There was great scope for this development, because they knew that diseases associated with these conditions were responsible not only for many deaths, but for a great deal of chronic ill-health. They wanted to encourage the most ample provision for maternity hospitals. Yet in spite of the optional nature of this clause, and in spite of the insertion of the word "reasonable," it was still possible under it that a maternity hospital would have charges so high that women who required the treatment very badly would not be able to take advantage of its facilities. Therefore he urged the Lord Advocate very strongly to concede the exemption of maternity hospitals from the general operation of the clause.

After further debate,

The clause was read a second time and added to the Bill.

An amendment moved by Dr. SHIELS, to exempt maternity homes from the clause, was rejected by 203 votes to 88.

The Committee stage was completed, and the Bill as amended was reported to the House.

HOSPITALS AND RELIEF OF RATING.

On Wednesday, Feb. 20th, Colonel GRETTON presented the Hospitals (Relief from Rating) Bill, a measure designed to grant complete or partial relief from rates in the case of certain hereditaments used for the purpose of hospitals, infirmaries, dispensaries, convalescent homes, nursing homes, sanatoria, and other similar uses or in connexion therewith. The Bill was read a first time.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 20TH.

Rating of Voluntary Hospitals.

Mr. ROBERT MORRISON asked the Prime Minister, in view of the increased burden of rates thrown upon the voluntary hospitals by the Rating and Valuation Act, 1925, whether the Government would introduce a Bill during the present session to remedy this, upon an assurance by all parties in the House that such a measure would be regarded as non-controversial.—Sir KINGSLEY WOOD replied: The Rating and Valuation Act made no alteration in the basis of the valuation of hospitals. It is open to the assessment authorities now, as heretofore, to adopt a basis which will take full account of the special circumstances of voluntary hospitals dependent upon contributions from the public and of the responsibilities, conditions, and restrictions which affect their rateable value. Full rights of objection and appeal are available to any governing body which is not satisfied that due regard has been paid to these factors and is aggrieved by the assessment proposed. As I indicated recently, the complete or partial exemption of hospitals from rating by statutory enactment could not be considered apart from the claims of other charitable and public institutions, and the introduction of legislation to that end could not be undertaken in the life of the present Parliament. I understand, however, that the British Hospitals Association are proposing to submit to the Central Valuation Committee proposals for promoting greater uniformity in the assessment of voluntary hospitals and the adoption of a generally acceptable basis of valuation.

THURSDAY, FEB. 21ST.

Workmen's Compensation.

Mr. TINKER asked the Home Secretary if he was in a position to give the total amount of compensation paid under the Workmen's Compensation Act for 1927, and the number of fatal and non-fatal cases that it covered.—Sir W. JOYNSON-HICKS replied: The total compensation paid in the year 1927 (the latest year for which figures are published) in the seven great industrial groups for which returns are collected was £5,315,803; the number of fatal cases was 2567 and the number of non-fatal cases 455,852. I regret that no corresponding figures are available for the other industries under the Act, but an estimate of the total amount paid in these industries in respect of workmen's compensation for 1927 is given on page 8 of the statistics.

Committee on Mental Deficiency.

Mr. ROBERT MORRISON asked the President of the Board of Education whether he had now decided to publish the report of the Departmental Committee upon Mental Deficiency, and when it would be available.—Lord E. PERCY replied: I am arranging for the publication of the first section of the report, which will include all the Committee's findings and recommendations on matters falling within the scope of my department and the local education authorities, together with the report of a survey of the incidence of mental deficiency in certain typical areas which was carried out for the committee by one of the medical officers of the Board of Control. These documents are not yet in print, and in view of their length I am afraid that they will not be available before Easter. I should like to take this opportunity of thanking the Committee for a most valuable report which I believe will be of the greatest assistance to all those interested in the education of mentally deficient children.

Sick Leave among Welsh Women Civil Servants.

Mr. SNELL asked the Minister of Health what was the average number of days of sick leave per head taken in each of the last three years by women clerical officers, writing assistants, and members of the established typing grades, respectively; and what was the number of days of sick leave taken in the case of each of the grades concerned on account of gastric and nervous troubles, respectively, in the Welsh Board of Health and in the office of the Registrar-General for England.—Mr. CHAMBERLAIN replied: The following is the information asked for: The average numbers of days sick leave per head taken in each of the last three years by women clerical officers, writing assistants, and members of the established typing grades in the Welsh Board of Health (A) and in the office of the Registrar-General for England (B), respectively, were as follows:—

	(A)			(B)		
	1926.	1927.	1928.	1926.	1927.	1928.
Women clerical officers.	6·83	5·75	4·72	10·0	6·7	17·5
Writing assistants ..	5.43	8·82	10·47	11·8	18·8	16·7
Established typing staff	3·25	8·3	10·25	16·5	21·6	18·5

The information asked for in the last part of the question could not be obtained without the expenditure of an undue amount of time and labour.

Removal of a Typhoid Patient.

Mr. SHIELDS asked the Minister of Health whether he was aware that Mrs. George Cromarty, of Sydney Cottage, Holy Island, Northumberland, on Oct. 20th, 1928, suffering from typhoid fever, was ordered by the medical officer to rise from her bed and dress and then conveyed in an ordinary four-wheeled cab to the mainland three miles over the sands, the tide being up and the cab awash all the way, and the patient being in a sitting position during the journey; that the order for removal was given by the

medical officer without medical examination of the patient and against the advice of the local practitioner; that Mrs. Cromarty died within a few minutes of being transferred to the ambulance which was waiting; that, had the removal been delayed for a few hours, the ambulance car could have carried out the removal from the island, and that provision for isolation on the island could have been arranged; and would he cause a full inquiry into the circumstances of Mrs. Cromarty's death.—Mr. CHAMBERLAIN replied: This case has not previously been brought to my notice, but I am causing inquiries to be made of the local authority, and will communicate the result to the hon. Member.

Duty on Radium Compounds.

Mr. WEDGWOOD BENN asked the Secretary to the Treasury the total duty collected, since its imposition, on radium compounds, and whether he had any information as to the amount of radium and radium compounds at present in this country.—Mr. A. M. SAMUEL replied: From Oct. 1st, 1921, to Jan. 14th, 1927, duty was chargeable on the following radium compounds only—viz.: radium bromide and radium barium chloride. The duty recorded as collected on these substances from Jan. 1st, 1922, to Jan. 14th, 1927, was £6. The figures for Oct. 1st, 1921, to Dec. 31st, 1921, are not available. From Jan. 15th, 1927, duty became chargeable on all radium compounds, and the amount of duty recorded as collected for the period Jan. 15th, 1927, to May 14th, 1928, when the duty was suspended, was £80. As regards the second part of the question, I would refer the hon. member to the reply given on Jan. 24th by the Minister of Health. I have no further information on the point.

MONDAY, FEB. 25TH.

Colonial Surgical Appointments.

Dr. SHIELS asked the Secretary of State for the Colonies if he was aware that in one colony certain surgical appointments were reserved for holders of the fellowship of a particular Royal College of Surgeons; whether this practice had the approval of the Colonial Office; and, if not, whether he would call the attention of the Colonial Government in question to the matter.—Mr. AMERY replied: I have been informed that in one of the colonies there is a departmental regulation that has the effect of excluding from consideration for certain surgical appointments candidates other than holders of a particular surgical diploma. I do not think that assignment to particular technical posts can fairly be based on academic qualifications alone, to the exclusion of other qualifications such as experience, skill, and personal suitability. I am inviting the attention of the Colonial Government concerned to the question.

Poisons and Pharmacy Acts Committee.

Sir WILFRID SUGDEN asked the Minister of Health when the Report of the Inter-Departmental Committee on the Poisons and Pharmacy Acts would be available, as its findings were essential to certain improvements in the interests of public convenience and health matters generally.—Lieut.-Colonel Sir V. HENDERSON (Under-Secretary to the Home Office) replied: I understand that the chairman of the Committee expects that the Committee's report will be submitted to the Lord President of the Council in the spring or early summer.

Rickets in Distressed Mining Areas.

Dr. VERNON DAVIES asked the Minister of Health what steps he was taking to deal with cases of early rickets in the distressed mining areas of South Wales and Monmouthshire, and if he was satisfied that these measures were adequate for all possible needs in the near future.—Sir KINGSLEY WOOD replied: The measures taken to prevent the onset of rickets and to deal with such cases as arise are a matter in the first instance for the maternity and child welfare authorities of these areas. My right hon. friend is advised that the authorities are alive to the importance of this matter, and he has recently sanctioned increased expenditure on the supply of milk to expectant and nursing mothers and young children in these areas.

Mr. PETHICK-LAWRENCE asked whether the cost of this milk was deducted by the guardians from the amount of relief given to the families

Sir KINGSLEY WOOD: No; there has been no deduction in these areas.

Dr. VERNON DAVIES asked whether the right hon. gentleman would communicate with the health authorities in order to see that cases of rickets were followed up after treatment.

Sir KINGSLEY WOOD said that he would look into that.

Mr. T. WILLIAMS asked if the right hon. gentleman was not aware that in the report submitted to the South Wales Mining Association it was definitely stated that the appointed commissioners were responsible for the reduction in the amount of grants for poor-law relief, and that that had contributed to a large number of cases of rickets.

Sir KINGSLEY WOOD said he was not aware of that report.

Mr. PETHICK-LAWRENCE: Is the right hon. gentleman not aware that I myself in this area was informed by the guardians that they had cut down the amount of relief to families where milk was given to the children.

Sir KINGSLEY WOOD: I cannot understand that, because there was no reduction made in the estimates in regard to milk in the distressed areas.

Miss WILKINSON asked whether the question was not whether the Department made a reduction, but whether it was a fact that the commissioners in the area and the poor-law authorities had deducted from the relief given to the families the cost of the milk given to the mothers.

Sir KINGSLEY WOOD: No; I am not aware of that, and there have certainly not been any instructions given by my Department to that effect.

Mr. SOMERVILLE asked whether far more relief was not being given now than in 1924.

Dr. VERNON DAVIES: Is the right hon. gentleman aware that this is not simply a question of shortage of food, but of improper food that the children are having?

Sir KINGSLEY WOOD: Yes, and I would remind the House that in the report just issued it was stated that to a great extent disease has been controlled by means of maternity and child welfare services.

Hygiene on Mercantile Vessels.

Dr. VERNON DAVIES asked the President of the Board of Trade if he was aware that during the years 1917 and 1918 certain amenities with regard to the hygiene of crews' spaces were enforced in standard ships; and whether these same amenities were still enforced by the Board of Trade.—Mr. H. G. WILLIAMS (Parliamentary Secretary to the Board of Trade) replied: The crew space arrangements on standard ships during the war were to some extent in excess of the regulation requirements of that time, and the present improved requirements are frequently exceeded on ships built now.

Dental Benefit in Scotland.

Mr. JOHNSTON asked the Secretary for Scotland whether he could say if insured persons in Scotland had a choice of dentist when receiving dental benefit; and, if so, under which clause or regulation.—The LORD ADVOCATE (Mr. W. WATSON) replied: Under para. 4 of Schedule C of the Scheme of Additional Benefits of an approved society providing dental benefit, an insured member is entitled to obtain dental treatment from any registered dentist who is willing to provide the treatment in accordance with the terms of the schedule and on the scale of fees, if any, for the time being recognised by the Committee of Management of the society. Where, however, the work or conduct of a dentist has been declared to be unsatisfactory a society may notify their members that that dentist is excluded from giving treatment under the schedule.

TUESDAY, FEB. 26TH.

Medical Practitioners and Mobilisation.

Mr. MALONE asked the Secretary of State for War whether he was aware that circular letters were being addressed by the district military headquarters to medical practitioners in the district requesting the practitioners to fill in a form stating whether, in the event of mobilisation, they would be willing to devote a portion of their time to work in the local military hospitals in order to fill the vacancies created by the withdrawal of regular Royal Army Medical Corps officers for the expeditionary force; whether this registration of doctors for military purposes was being carried out all over the country on his instructions; and, if so, with what object.—Sir L. WORTHINGTON-EVANS replied: Inquiries are being made by the military authorities in various parts of the country to see how far the local civil medical practitioners can be counted on in the event of mobilisation to act in a civil capacity in hospitals in the United Kingdom in place of Royal Army Medical Corps officers until relieved by other Royal Army Medical Corps officers.

Pensioners and Treatment Allowances.

Mr. BELLAMY asked the Minister of Pensions, seeing that great hardship was inflicted on the families of men undergoing treatment in cases where allowances were not payable several persons, women and children, having to live on a flat-rate pension of 8*s.* a week in some instances, and that a pensioner undergoing institutional treatment could not accept or follow a remunerative employment, if he would authorise the payment of full treatment allowances in all cases of institutional treatment whether the pensioner was in employment or not when admitted.—Lieut.-Colonel STANLEY replied: Special allowances during treatment are, as my right hon. friend has more than once explained, payable only where the man has incurred loss by having to give up a remunerative occupation in consequence of the treatment; and allowances are nevertheless paid (both

the case of in-patient and other forms of treatment) where the man is proved to be ordinarily an earner, notwithstanding that he may have been temporarily out of employment at the time of commencing treatment. There would be no justification for the payment of these special allowances in cases where there is no evidence to indicate that, apart from the course of treatment, the men would be engaged in remunerative occupation, and their ability to provide for themselves and their families is therefore not adversely affected by their treatment.

Medical News.

UNIVERSITY OF OXFORD.—In Convocation on Feb. 26th a decree was passed to discontinue the examinations for the Diploma of Public Health until further notice.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were successful in the undermentioned subjects:—

Surgery.—T. A. Barnabas, Bristol; C. M. Brooks, Durham; N. Das, London Hosp.; H. W. E. Dickey, Manchester; R. Frankling, Guy's Hosp., K. E. Gallaher, Manchester; and K. Girgis (Section I.), Manchester and Charing Cross Hosp.

Medicine.—W. A. A. Collington, Guy's Hosp.; H. M. Feldman, Leeds; L. P. Gregory, Bristol; C. K. McCoan, St. Mary's Hosp.; and C. F. C. White, Guy's Hosp.

Forensic Medicine.—C. W. Ellison, St. Bart's. Hosp.

Midwifery.—R. K. Nandlal, Birmingham, and C. Skinner, Guy's Hosp.

The Diploma of the Society was granted to the following, entitling them to practise medicine, surgery, and midwifery:—T. A. Barnabas, C. M. Brooks, W. A. A. Collington, N. Das, L. P. Gregory, C. K. McCoan, and C. F. C. White.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Feb. 20th an offer by the trustees of the late Mr. C. H. Clark of a sum of £10,000 for the establishment of a Lectureship in the History and Progress of Preventive Medicine and Tropical Hygiene was accepted with thanks.

The Senate also accepted with thanks a grant of £1000 from the Beaverbrook Fund for Medical Research, which had been forwarded by the Prime Minister. The grant will be applied to the purposes of, and administered under, the scheme for the Thomas Smythe Hughes Medical Research Fund.

Prof. W. E. Le Gros Clark, F.R.C.S., was appointed as from Sept. 1st, 1929, to the University Chair of Anatomy tenable at St. Thomas's Hospital Medical School. In 1924 Prof. Le Gros Clark was appointed to the University Readership in Anatomy tenable at St. Bartholomew's Hospital Medical College and in 1927 to the University Chair of Anatomy there.

Mr. T. G. Hill, D.Sc., was appointed to the University Chair of Plant Physiology and Mr. E. J. Salisbury, D.Sc., to the Quain Chair of Botany, both tenable at University College.

A degree of Ph.D. was instituted in non-clinical subjects for both internal and external students in the Faculty of Medicine.

The Geoffrey E. Duveen Travelling Studentship in Oto-Rhino-Laryngology, of the value of £450, was awarded for 1929 to Mr. Nehemiah Asherson, M.B.

On the recommendation of the School Committee of University College Hospital Medical School, Mr. G. R. Cameron, M.B., has been appointed to the Graham Scholarship in Pathology for two years from Sept. 1st, 1928.

A course of three lectures on Some Biological and Epidemiological Aspects of Helminthic Infection will be given by Prof. F. Fülleborn (of the Institut für Schiffs- und Tropenkrankheiten, Hamburg), at the London School of Hygiene and Tropical Medicine (25, Gordon-street, W.C. 1) on Monday, Tuesday, and Wednesday, March 11th, 12th, and 13th, at 5.30 P.M. At the first lecture the chair will be taken by Dr. G. Carmichael Low.

COLLEGE OF PESTOLOGY.—A luncheon was held at the Hotel Cecil on Feb. 20th, at which the chairman of the College of Pestology, Mr. A. Moore Hogarth, was presented with his portrait in oils. The President, Sir William Bull, who was in the chair, read a letter of felicitation from Sir Thomas Horder, the Deputy President, who was prevented from attending. The presentation was made by Prof F. T. G. Hobday, and Mr. Hogarth, in reply, recounted the experience which had led him to found the College and suggested that the time had come for a change of name, possibly to the "College of Microbiology."

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE. A course in general medicine and surgery, including the special departments, with special reference to recent advances in these subjects, will be held at the West London Hospital, Hammersmith, from March 11th to 23rd.

WEST END HOSPITAL FOR NERVOUS DISEASES.—A Savill Prize, value £15, is offered for a thesis on a neurological subject approved by the examiners before April 9th. Candidates must have attended the practice of the hospital at least ten times and theses must be received not later than Oct. 31st. Further information may be had from the Secretary of the Hospital, Welbeck-street, London, W. 1.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—The annual general meeting of this Association will be held at the Rooms of the Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C., on Friday, March 15th, at 5 P.M. (tea 4.30 P.M.), when Sir Henry Gauvain will read a paper on Combined Education and Treatment of Children Suffering from Physical Defects.

COURSES FOR DIPLOMA IN PSYCHOLOGICAL MEDICINE. Lectures and practical courses at the Maudsley Hospital, Denmark Hill, S.E. have been arranged by the London County Council, beginning on March 6th. Particulars may be had from the Director of the Central Pathological Laboratory at the hospital. There is also opportunity for clinical experience and instruction, concerning which application should be made to the Medical Superintendent.

POST-GRADUATE FACILITIES IN MANCHESTER.—The post-graduate lectures and demonstrations at Manchester Royal Infirmary have been resumed and will be held each Tuesday (except April 2nd) till May 14th. On Fridays, from March 1st, demonstrations of clinical cases and methods will be given in the wards and special departments. These will be continued (except on March 29th and April 5th) till May 10th. All the lectures and demonstrations will commence at 4.15 P.M. (tea at 3.45 P.M.). Post-graduate lectures at Ancoats Hospital are also being continued this session on certain Thursdays at 4.15 P.M. (tea at 3.45 P.M.). Notices of lectures at both hospitals will be found weekly in our Medical Diary.—A post-graduate intensive course in obstetrics and gynæcology will be given at St. Mary's Hospital, Whitworth-street, Manchester, from Saturday, June 15th, to June 22nd, inclusive. Further particulars of this and other courses can be obtained from the Dean of the Medical School at the University.

HOSPITAL ACCOMMODATION IN THE IRISH FREE STATE.—In a brief debate on this subject in the Senate last week, the MacGillicuddy of the Reeks moved that the Minister for Local Government and Public Health should exercise his powers to ensure that adequate hospital accommodation should be provided in the County Kerry at an early date. He said that the present accommodation was inadequate, and patients under treatment had to be removed prematurely to make place for others. Sir Edward Bigger urged that a wider issue should be considered. He thought that a committee should be appointed to investigate the whole question of the provision of treatment for major operations. In his reply, the Minister did not touch on the larger question, but stated that the case of Kerry was receiving full consideration.

BILLROTH CENTENARY CELEBRATIONS IN VIENNA.—Medical men and scientists from all over the world will honour the memory of the great Austrian surgeon, Theodore Billroth, in April next, in which month the hundredth anniversary of his birthday occurs. The Medical Faculty of the University of Vienna, the Vienna Academy of Science, and the Medical Society of Vienna have united to organise special centenary celebrations on April 9th and 10th in the city where Billroth practised and taught, and it is expected that the medical professions and scientific associations of many foreign countries will be represented. The idea of holding centenary celebrations originated in the small circle of those in Vienna who can claim to have had the privilege of learning at the feet of the great teacher of surgery, but Billroth's disciples and admirers are to be found in the chairs of medicine and surgery of every country in the world and not only in Austria and Germany. Full particulars of the centenary celebrations can be obtained from the Akademie der Wissenschaften in Wien (Universitätsplatz 2, Vienna I.).

MUNICIPAL SUN LOUNGE.—What is described as the first municipal sun lounge to be built in Great Britain was opened at Torquay on Feb. 20th by Dr. Leonard Hill, F.R.S. Ninety-five feet long, it faces due south and has walls and a roof of vitaglass.

STIRLING ROYAL INFIRMARY.—By the opening of the new maternity block, the extensions to this hospital, which have cost £108,000, have been completed. There are now 20 beds in this part of the institution, provided one-half by the Stirling Town Council and one-half by the Central District Committee of Stirling County Council.

WORK OF ST. GEORGE'S HOSPITAL.—Speaking at the annual general meeting of the Ladies Association at St. George's Hospital last week, Sir Crisp English, the senior surgeon, said that the hospital averaged about 500 night emergency operations a year. There are 4000 operations annually and four new operating tables are badly needed. There had been 180,000 out-patients and 24,000 in-patients in the electrical massage department. Without having any definite research endowment, the hospital was doing cancer research in a quiet way in the course of clinical work, and influenza research was being pursued.

SCOTTISH HOSPITALS.—The report by the managers of the Glasgow Royal Infirmary shows a shortage of £10,127 on the year's working, and for the first time for many years it has been necessary to borrow money from the bank. There were 16,488 in-patients under treatment during the year, the average number resident daily being 783·8 and the average period of residence 17·4 days. A total of 97,258 outdoor patients were treated in dispensaries and other departments. The total ordinary revenue for the year was £87,815, and the total ordinary expenditure £122,178. 130 beds and 11 cots are now endowed and the restricted capital funds amount to £295,830. Through the generosity of Mr. William C. Teacher, of Cive, Dumbartonshire, who gave £10,000 for the purpose, a University lectureship in bacteriology at the Royal Infirmary has been founded.—Aberdeen Royal Infirmary's annual report refers to the numerous cases resulting from motor accidents, which have created a two-fold problem by the expense they involve and by the prolonged occupation of beds that are required for other purposes. The decision of the Students' Representative Council to suspend their gala week in 1929, the report continues, is regretted. While fully recognising the stupendous amount of time and labour which the gala involves, the directors say that they cannot but view with concern an interruption in what has come to be regarded as a regular and considerable source of revenue for the infirmary. They therefore venture to hope that some time this year the students may find it possible to do something which will provide a contribution to the infirmary funds, and maintain continuity of the methods of organisation and administration which have hitherto proved so successful. The total number of patients admitted to the infirmary last year was 31,115, an increase of 2647 over those admitted in 1927.

DRUGS FOR INSURED PERSONS: APPOINTMENT OF AN ADVISORY COMMITTEE.

IN order to assist insurance committees to proceed on uniform principles in dealing with questions of difficulty as to the definition of drugs and medicines for the purposes of medical benefit under the National Health Insurance Acts, the Minister of Health has now appointed an advisory committee. This committee is to consider and report to the Minister upon questions which he refers to them. Certain questions which are known to have occasioned difficulties of definition in the past have already been referred to it; any further proposal should be submitted in the first instance to the Medical Department of the Ministry accompanied by full particulars of the circumstances in which a difficulty of definition has arisen. The membership of the committee is as follows: Dr. Dudley G. Greenfield (chairman), Mr. T. Allsop, J.P., Dr. J. J. Day, Sir Walter Fletcher, F.R.S., Mr. J. E. French, M.P.S., Dr. A. F. Heald, Mr. W. Gill Hodgson, Mr. E. Lewis Lilley, F.R.C.S., Mr. F. Llewellyn-Jones, LL.B., Mr. G. A. Mallinson, Mr. Edwin Potts, B.Litt., Mr. Philip F. Rowsell, F.C.S., Mr. Thomas Tickle, F.I.C., with Miss E. M. R. Russell (secretary). All communications should be addressed to the secretary of the Advisory Committee on the Definition of Drugs, Ministry of Health, Whitehall, London, S.W. 1.

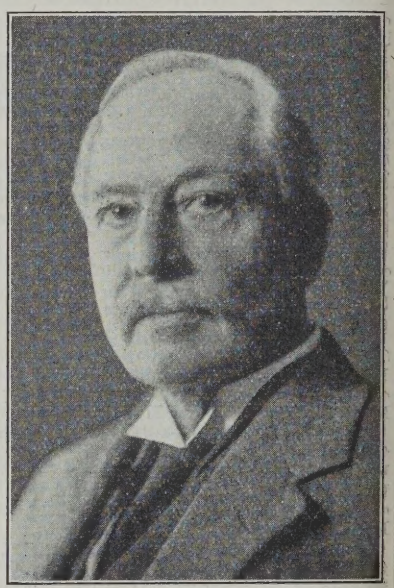
Obituary.

GEORGE NEWTON PITT, O.B.E., M.D. CAMB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

WE much regret to announce the death of Dr. Newton Pitt, which occurred at his house, Southdene, Walton-on-Thames, on Friday, Feb. 22nd, in the seventy-fifth year of his age.

George Newton Pitt was born in London in 1853, the eldest son of the late Mr. George Pitt, of Sutton, Surrey. He was educated at Christ's College, Finchley, whence he proceeded with a scholarship to Clare College, Cambridge, and after a distinguished career as a student graduated in 1876 as tenth wrangler, being duly elected Fellow of his college later. Deciding to enter the medical profession, he joined the medical school at Guy's Hospital in 1878, took the M.R.C.S. Eng. in 1881, graduated in medicine at Cambridge, where he proceeded to the M.D. in 1884, the same year in which he took the M.R.C.P. Lond. After post-graduate work in Vienna he was elected assistant physician at the East London Hospital for Children, and in 1887 assistant physician to Guy's Hospital, after a short period as medical registrar. As assistant physician, and ten years later as full physician, Pitt remained on the staff of the hospital his full term, being elected consultant physician just before the war. His long and intimate association with the hospital is well brought out in the following note from his friend and colleague, Sir William Hale-White:—



DR. NEWTON PITT.
Photograph: Elliott & Fry.

"George Newton Pitt came to Guy's in 1878 with a considerable mathematical reputation from Cambridge. He had already done his anatomy and physiology and so he passed at once into the wards and held all the usual appointments, including that of house physician. The members of the staff for whom he worked most and who chiefly attracted him were Howse and Moxon, both then at the height of their notability as great teachers. Pitt became medical registrar and in 1887 was appointed assistant physician at the same time as Sir Cooper Perry and Leonard Charles Wooldridge. He remained on the active staff until he retired under the age limit of 60 shortly before the war. He had not been long among his fellow medical students before they discovered that there had come among them a very lovable man; he made many friends, perhaps the closest was that remarkably brilliant man Ryle, the brother of the late Bishop Ryle, Dean of Westminster, and the father of Dr. Ryle, now on the staff at Guy's. He and Pitt lived together for a time, and it was a real pleasure to spend an evening with them

You could not help being fond of Pitt, his kindness, his equanimity, and serenity compelled your affection. If you were ill he came to see you and you felt encouraged by his visit. His feeling for the unfortunate and his desire to help them actively was shown by the assiduity and industry with which, for many years, he gave endless time and patience while carrying out his duties as hon. secretary to the Royal Medical Benevolent Fund. Waves of troubles, whether his own or those of others, passed over him, leaving him uninjured and just as fresh as ever to throw his best energy into repairing the mischief. A few years ago he suffered severely and for a long while from sciatica, but to his visitors he was always cheerful, and likewise in his fatal illness it was the same; he was pleased to see a friend and optimistic about himself. He was one of the few who was never known to have an enemy, and the more you saw of him the more you admired in him the nature that never sought its own advantage, was always generous in its appreciation, indefatigable in its service for others. The same characteristics came out in Pitt the physician; he took infinite labour to discover what was the matter with his patients, in his desire to relieve them no trouble was too great, in the same way he was unwearying in the pains he took to teach the students attached to him."

Newton Pitt's connexion with the Royal College of Physicians of London was an important one. Elected F.R.C.P. in 1889, he was Goulstonian lecturer in 1890, Bradshaw lecturer in 1910, and senior censor in 1918. He acted also as examiner in medicine at the Conjoint Board, as well as for the Universities of Cambridge and London at various times. The subject of the Goulstonian lectures was Cerebral Lesions, and in the series of three discourses the lecturer summarised very clearly contemporary knowledge upon the fatalities of ear disease, the manifestation of meningitis, cerebral abscess, and sinus thrombosis having origin other than in disease of the ear, and the signs and symptoms of cerebral embolism and aneurysm, as recorded in the Guy's Hospital Reports. In the Bradshaw lecture, delivered 20 years later, he discussed fully the results of bronchial obstruction, and again showed his high ideal of the responsibilities of the hospital physician by basing his observations and teaching upon the Guy's Reports. He was an infrequent writer, but in a contribution to Allbutt and Rolleston's System, upon right-sided valvular lesions of the heart, the same anxiety to base his observations upon the records of Guy's Hospital and other institutions, where the evidence could be confirmed or challenged, is apparent.

Another side of his work was his charitable energy exerted on behalf of the less fortunate members of the medical profession. For many years he was secretary of the Royal Medical Benevolent Fund, and of his labours in this cause the treasurer of the Fund, Sir Charters Symonds, writes as follows:—

"The Royal Medical Benevolent Fund has lost by the death of Dr. Newton Pitt not only a warm supporter but an untiring Hon. Secretary. During the 15 years he acted in this capacity his interest never flagged, and his wide knowledge of the various charitable agencies which might contribute to the necessities of those with whom he was immediately concerned proved of great value. The work of investigating the applications for relief fell upon him and involved not unfrequently personal inquiries as well as correspondence in order to confirm various statements or obtain additional information. His wise discrimination in these inquiries, and the manner in which the cases were presented, enabled the committee to adopt his decisions with confidence. It will be readily understood that the investigation of about a dozen new applications each month, and the review of some 20 to 30 old cases, involved considerable labour. Dr. Pitt, however, never failed, nor was he ever more informing and accurate than at the last meeting he attended a week before his death. Not only did he know the history of the many beneficiaries receiving grants, but also that of the numerous annuitants. In financial matters his mathematical acquirements (he was a Cambridge Wrangler) and logical outlook proved of essential service. In the larger questions of policy his clear vision and long views guided the Fund through many difficulties. The growth in the activities of the Fund during his secretaryship will be appreciated when it is mentioned that when he took over the duties there was one part-time secretary, while at present there are three clerks constantly at work under a salaried secretary, and the number of grants made and of annuitants benefited has risen proportionally.

When the War Emergency Fund was started by the late Dr. Samuel West in 1916, the duties of secretary devolved upon Dr. Pitt, and into this branch of the work he threw his energy and interest, interviewing with other members of the special committee many of the applicants, promoting the education of some 150 boys and girls, and enabling many practitioners to resume their practices or to find new positions. One of his last acts was to wind up this Fund, having taken a leading part in the administration of the £30,000, two-thirds of which had been raised by the profession, the remainder being a contribution from the National Service Fund. It will not be easy to find another possessing such abilities and such devotion. His unfailing courtesy, his unruffled temper, his fine sense of comradeship, his appreciation of the views of others, will long be remembered by those associated with him in his charitable work."

EDWARD LEICESTER ATKINSON, D.S.O., M.R.C.S. Eng.

Surgeon-Captain E. L. Atkinson, R.N., who died on Feb. 20th and was buried at sea, was a man whose life brought credit to his profession.

The son of Mr. and Mrs. E. L. Atkinson, of Trinidad, he was born in 1882 and was educated at Forest School. From there he entered St. Thomas's Hospital, where he held house appointments after qualifying in 1906. As a student he already showed the toughness of character and physique that distinguished his later career, and he gained the United Hospitals light-weight boxing championship in 1905. On entering the Royal Navy he passed out top of his batch at Haslar and was awarded a medal.

In 1910 Atkinson joined Captain Scott's Antarctic expedition. During the long and arduous voyage south in the *Terra Nova* he became the close friend of Captain L. E. G. Oates, a circumstance that may be recorded as a hall-mark of high honour. Throughout the expedition he distinguished himself as a man who sought arduous duties for the satisfaction they brought him. In the second autumn, when the *Terra Nova* returned to the base at Mount Erebus, expecting to bring home the whole expedition, two sledging parties were missing. The first was the Geographical Pole Party under Captain Scott, the other the Northern Party, who were away sledging in the direction of the magnetic pole. To avoid the possibility of entanglement in the winter ice, it was needful for the ship to return to New Zealand, and Atkinson was left at the base in charge of a party to spend the winter there and render assistance to any that might have survived. Those who had gone off in the hope of finding Scott and his companions returned without news of them. Meanwhile Atkinson made a strenuous attempt to succour the Northern Party but was baffled by the ice conditions. After spending the winter at the base, and in the belief that neither of the missing parties would have survived the winter, Atkinson led his party off to search for the bodies and records of Captain Scott and his companions. He found the bodies of Captain Scott, Dr. Wilson, and Lieutenant Bowers a hundred miles away to the south. Eighteen miles further Captain Oates had made his historic sacrifice in walking out to his death in a blizzard to save his companions. Failing to find his body, Atkinson

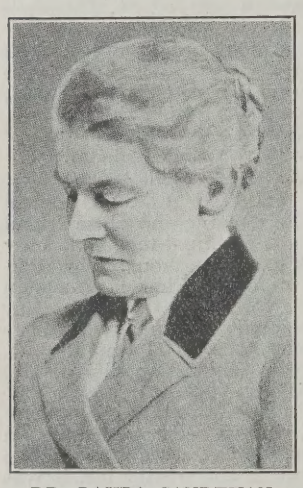
erected a cairn to his memory, marked with the now classical epitaph: "Hereabouts died a very gallant gentleman."

Atkinson's career during the war was exactly in accordance with his character. After service with the Grand Fleet he went with the Royal Naval Division to Gallipoli, and later served with a howitzer brigade in France, where he was badly spattered in the face by a bursting shell, partly losing the sight of one eye. After this he served in H.M.S. *Glatton* at Jutland. When the ship was torpedoed and sinking a fire broke out. Atkinson went below and brought up a man. He was almost blinded, but made his way down again, bringing another man up. He then became unconscious. This act of his was not known until his commanding officer, who was himself wounded, long afterwards collected the evidence and recommended him to the notice of the Admiralty. He was awarded the Albert Medal and the D.S.O.

In March, 1920, Atkinson won the Chadwick gold medal and prize given once in every five years for special work in promoting the health of the Navy and Army. He had done good scientific work in helminthology and bacteriology, having a clear and exceptional scientific mind, which might have gained him distinction in research if his health had not been severely damaged by the hardships and wounds he had suffered. His death at sea was a fitting circumstance and one that he himself would have desired.

LAURA STEWART SANDEMAN, M.D. EDIN., J.P.

THE death of Dr. Laura Sandeman last week, as the result of influenzal pneumonia, has cast a gloom over the city of Aberdeen in which she was described without exaggeration as the best-loved woman. The eldest daughter of a large Perthshire family, she was already familiar with public work before taking a medical course at Edinburgh University. Qualifying in 1903, she settled in Aberdeen and soon became family physician to the east end of the city, whilst losing no opportunity of social or public health service. Having started in her teens to inaugurate a sewing class and savings bank in her native village, she was the first to see the need for a centre in the poor and crowded district of Torry, at which mothers could attend and bring their babies for advice and treatment, and as time went on her advocacy of child welfare possessed her more and more, and she was widely in request as a lecturer on this and kindred subjects. At the outbreak of the late war Dr. Sandeman brought herself only after a struggle to depute her work in Aberdeen to others and to join the staff of the Scottish Women's Hospital in France, which she left to become controller of medical services to Queen Mary's Army Auxiliary Corps, her organising ability when given free scope proving to be of a high order. The same ideal of citizenship entered into her political work, for on her last appearance on the political platform she urged her fellow-women to make use of their suffrage, to whichever party they adhered. Twice she stood without success for North Aberdeen, on the former occasion returning from a continental holiday to canvass the constituency. Her death has called out on all sides testimonies to her ability and singlemindedness which may be summed up in the words of a colleague: "She had qualifications for public service of the highest order; she was in addition a woman who inspired affection and who made richer the lives of all who knew her." Dr. Laura Sandeman's death at 67 years of age makes the first gap in a family circle which includes Mr. James Sandeman, K.C., Sheriff of Perth, and Mr. A. N. S. Sandeman, M.P. for Middleton and Prestwich.



DR. LAURA SANDEMAN.
Aberdeen Press and Journal.

DENIS WALSHE, M.D. N.U.I., J.P.

Dr. Denis Walshe, whose death occurred last week at Craiguenamanagh, Co. Kilkenny, in his eighty-fourth year, was one of the most highly respected general practitioners in Ireland. A student of the old Catholic University in Dublin, he took the licence of the Royal College of Surgeons of Edinburgh in 1869, and of the King and Queen's College of Physicians of Ireland in 1871. In 1915 the honorary degree of M.D. was conferred on him by the National University of Ireland. In his younger days he practised for several years in England, but over 40 years ago he returned to his native country and was appointed medical officer of the Graigue dispensary district. He also held for many years the office of coroner for the county of Kilkenny. Engaged in a busy country practice, Dr. Walshe kept his mind open to the advances of medical knowledge, and he was regarded both by his colleagues and the public as a sound and wise practitioner. It is more than 50 years since he first contributed to our own columns a note on ligature of the femoral artery in two cases under his care, the material being the newly introduced carbolised catgut. He interested himself in public affairs, and had been chairman of the County Kilkenny Insurance Committee since its foundation in 1912. He was active in the various medical organisations, in which his wise judgment carried great weight. For many years he represented the South-Eastern of Ireland Branch on the Council of the British Medical Association. His geniality, his hospitality, and his sturdy upright character gained him respect and affection everywhere. To his colleagues he was a loyal and helpful friend, to his patients a trusted and wise adviser.

JOHN LOGAN STEWART, M.B. GLASG., D.P.H.

Dr. Logan Stewart, who died of pneumonia in Manchester on Feb. 20th, in his fiftieth year, was consultant tuberculosis officer to the Lancashire County Council. He graduated at Glasgow M.A. in 1900 and M.B., Ch.B. in 1905, adding the D.P.H. Camb. three years later. He then entered the service of the council as medical inspector of schools, and in July, 1913, he was appointed to supervise the tuberculosis service in the south-eastern section of the county (with a present population of 370,000), with a chief dispensary at Ashton-under-Lyne and five branch dispensaries in neighbouring towns. Dr. Stewart was the first member of the county tuberculosis staff to undertake his own X ray work, and this he developed to a high degree of efficiency. Several of his contributions may be read in the annual reports on tuberculosis work in Lancashire, and his views on the value of X ray work in a tuberculosis dispensary were set out in an article which appeared in *Tubercle* in 1927. He also did pioneer work in the treatment of tuberculosis by artificial light, demonstrating its use particularly in the treatment of lupus and adenitis with abscess formation and skin involvement. Latterly he had devoted much time to the relation of tuberculosis and silicosis, his preliminary report being published in the current issue of the *British Journal of Tuberculosis*.

Dr. G. Lissant Cox writes: "In the last 10 or 15 years the tuberculosis service in the North of England has had two exceptionally gifted clinical tuberculosis officers—the late Dr. W. C. Rivers, district tuberculosis officer of the West Riding County Council, and John Logan Stewart. Stewart was a

typical Lowland Scot. Austere yet kind, bent but not broken by the death of his wife some three years ago, engrossed in his work, possessed with a sure judgment and an entirely unselfish nature; these qualities made him loved and respected by all his colleagues, patients, and the doctors who so frequently consulted him. Visitors from many lands went to Ashton-under-Lyne; all returned impressed with Stewart's work. But this it was which made him stand out above the crowd: Woven into every part of his being and controlling his unceasing work was a fierce yet sane sympathy with the sufferer from tuberculosis. For such sufferers he lived, and for them he died."

Dr. J. R. Kerr writes: "The passing of John Logan Stewart will be regretted with particular poignancy by his old classmates of Glasgow University. One remembers the steadfast honesty of his mind and the most lovable gentleness of his manner. Whatever Stewart set his hand to he did with all his might. Many will miss his counsel as a tuberculosis specialist, as an expert in the radiology of the chest, or in the theory and practice of ultra-violet ray treatment. But all who knew him will cherish the memory of his sterling character and of his full-hearted devotion to the cause of the suffering."

WALTER AUBREY KIDD, M.D. LOND., F.R.S. EDIN.

WE regret to announce the death of Dr. Walter Aubrey Kidd, who died on Thursday, Feb. 21st, at Cape Town, in the seventy-sixth year of his age. A son of the late Dr. Joseph Kidd, the well-known physician of Blackheath, and the brother of Dr. Percy Kidd and Mr. Frank Kidd, he was educated at Uppingham, whence he proceeded to the medical school at Guy's Hospital. Here he had a very successful career, graduating at the University of London as M.B., B.S. in 1876 with honours and the gold medal for forensic medicine. He proceeded to the M.D. in the following year, having immediately after his residence at Guy's Hospital begun to practise medicine at Blackheath. Here by individual merit as well as family connexions, he enjoyed a very large practice, from which he had recently retired.

Walter Kidd was an original and observant student of the problems of heredity, and his communications to our pages on this and allied subjects were always of interest, while he was the author of several thoughtful monographs having similar scope, for example, an essay on Use-Inheritance, and two such books, entitled the "Direction of Hair in Animals and Man," and the "Sense of Touch in Mammals and Birds."

GEORGE VERE BENSON, M.A. CAMB., M.R.C.S. ENG.

AFTER a long period of ill-health Dr. G. V. Benson died at Lewes on Feb. 21st at the age of 81. He was a familiar figure in East Sussex, inasmuch as for 28 years he was coroner for what is known as the Lewes district, which comprises the greater part of the administrative county of East Sussex, and also Eastbourne. He was appointed to this office in 1899 by the casting vote of the then chairman of the county council, who wanted to see a medical man holding the coronership instead of the customary solicitor. Dr. Benson had at that time had several years' experience of the work, having been for five years deputy coroner for the western division of Middlesex. In East Sussex he is said to have conducted at least 6000 inquests, and when Eastbourne became a county borough entitling it to elect its own coroner, the corporation decided to continue his appointment as showing appreciation of his services. He retired in 1927.

Dr. Benson was born in Dublin, his father being Mr. Charles Benson of that city. He was educated at Trinity College, Dublin, and Downing College, Cambridge. At Cambridge he was placed as a wrangler in the mathematical tripos, after which, embarking on the study of law, he was called to the Bar in 1878. Some years later he decided to study medicine, and qualified in 1893. From 1908 to 1910 he was vice-president of the Coroners' Society of England and Wales. A somewhat prolific writer, he contributed, inter alia, to the "Encyclopædia of the Laws of England," and "The Dictionary of National Biography."

Dr. Benson married a daughter of David Bateman Thornton, by whom he had one son.

MISS HELEN HUNTER BAILLIE, who died in London on Feb. 11th in her eighty-sixth year, was the last of the third generation in descent from Dorothea, the sister of John Hunter, "the founder of scientific surgery" and the creator of the museum of the Royal College of Surgeons of England. Of the nine brothers and sisters of John Hunter, only Dorothea married, and the children of John Hunter all died without issue. The fourth generation from the Hunters is now represented by the children of her sisters, Mrs. Oliver and Mrs. Maconechy. Of the former there are four living—the Rev. Robert Baillie, Helen, Dorothy, and Angela Oliver. The eldest, Rachel, died a martyr to devotion to hospital work. The second son, Matthew M. B. Oliver, F.R.C.S., well known as an ophthalmic surgeon, died in 1926. Of the three daughters, Muriel, Sophia, and Joanna, of Mrs. Maconechy, the eldest, Muriel, married Thomas B. Jobson, M.D., of Netherwood, Guildford. Thus the fourth generation is represented by but seven. The fifth generation is reduced to four, the one son, Patrick Hunter Jobson, and three daughters of Mrs. Muriel Jobson.

Miss Hunter Baillie's devotion to medicine and especially to "the College" was great. With loving care she guarded the pictures, relics, and letters of the Hunters, William and John, and finally placed them in their present resting place under the care of Sir Arthur Keith at the Royal College of Surgeons. Until a year or two ago she attended the Hunterian Orations and much enjoyed the courtesy with which she was received. She had a rare gift of letter writing, and corresponded regularly with her many friends up till the last. A woman of great personality, in the opinion of Sir Arthur Keith she inherited to a remarkable degree the features of body, face, and mind of her distinguished ancestor. At the Hunter Centenary Dinner of the College of Surgeons last year she was an honoured guest, and she was an honorary member of the Hunterian Society of London.

THE Chadwick Trustees invite "British subjects between 25 and 30 years of age, who have graduated in a British university or who can produce evidence of attainments or of intellectual equipment proving themselves to be capable of methodical study and research," to apply for two Travelling Scholarships of £400 each to enable the holders to travel abroad during one year to study methods adopted in other countries for the prevention of disease and the improvement of the public health. At the discretion of the Trustees the scholarships may be renewed for a second year. Before appointment a candidate will be invited to submit for the approval of the Trustees a scheme of study and an itinerary which it is proposed to follow. This opportunity is offered to male and female candidates.

ENDOWED DREADNOUGHT BEDS.—Sir George Hume, M.P., recently unveiled a bed in the Dreadnought Seamen's Hospital at Greenwich, the ninth which has been endowed by the Seamen's Hospital Aid Committee in memory of the men of the merchant service who died during the late war. The remainder of the 12 beds in the Northumberland Ward will shortly be endowed through the efforts of the Aid Committee; the Millwall Football Club has promised to endow one of them.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, March 5th.—8 P.M., PATHOLOGY. Laboratory Meeting in the Pathological Department, St. Thomas's Hospital Medical School, S.E. Communications: J. Bamforth: Two Cases of Purpura with Unusual Blood Pictures for which Splenectomy was Performed. R. J. V. Pulvertaft: Experiments with Streptococcal Toxin and Hæmolysins. J. O. Oliver: Group Complement Fixation with the Gram-negative Cocci. 8.30 P.M., ORTHOPÆDICS. Discussion on the Diagnosis and Treatment of Low Back Pain. Opener: Dr. M. Smith-Petersen (Boston, U.S.A.). To be followed by Sir Robert Jones, and others.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Demonstrations: Mr. C. J. S. Thompson will show an unknown portrait of Ambroise Paré. The President will show other portraits of Ambroise Paré. Paper: Dr. R. Campbell Thompson: Assyrian Remedies for Diseases of the Ears. 5 P.M. (at the Middlesex Hospital, W.), SURGERY. (Tea will be served at 4.30 P.M.) Paper: Prof. Sidney Russ: Some Principles of Dosage in Radium Therapy. A demonstration of cases treated with radium by the surgeons of the Middlesex Hospital will follow.

THURSDAY.—8.15 P.M., TROPICAL DISEASES. Paper: Mr. T. W. M. Cameron: Some Parasitic Problems in the British West Indies.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.) Cases will be shown demonstrating diseases of the endocrine glands. 5 P.M., OPHTHALMOLOGY. Clinical Meeting at the University College Hospital, Gower-street, W.C. (Tea at 4.30 P.M.)

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

WEDNESDAY, March 6th.—9 P.M., Dr. H. W. Barber: Dermatology in Relation to Other Branches of Medicine. (Third Lettsomian Lecture.)

HUNTERIAN SOCIETY.

MONDAY, March 4th.—9 P.M. (in the London Mansion House), Prof. A. W. Sheen: Some Aspects of the Surgery of the Spleen, illustrated by lantern slides. (Hunterian Oration.)

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY, March 4th.—8 P.M., Sir Thomas M. Legge: Thirty Years' Experience of Industrial Maladies. (Third Shaw Lecture.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, March 5th.—5 P.M., Dr. J. Graham Forbes: Past and Present Diphtheria in England and Wales with special reference to the London Metropolis. (Last Milroy Lecture.)

THURSDAY.—5 P.M., Prof. E. B. Verney: Polyuria. (First Goulstonian Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, March 4th.—5 P.M., Mr. C. E. Shattock: Specimens Illustrating Diseases of the Tongue and Lips.

FRIDAY.—Prof. Sir Arthur Keith: The Anatomy and Pathology of "Diverticulitis."

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 4th to SATURDAY, 9th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., at 5 P.M., Lecture by Mr. Herbert J. Paterson: Pitfalls in Radiology.—ST. MARK'S HOSPITAL, City-road, E.C., on Thurs., at 5 P.M., Demonstration by Mr. E. T. C. Milligan: Diseases of the Rectum.—WELLCOME MUSEUM OF MEDICAL SCIENCE, 33, Gordon-street, W.C., Wed., at 4 P.M., Demonstration by Dr. S. A. Henry: The Industrial Cancers and their Importance in the Investigation of the Problem of New Growth.—The above are free.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Post-graduate course in Dermatology, every afternoon, and some evenings.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Post-graduate course in Diseases of Children, mornings only. Lectures, demonstrations, operations. Further particulars from the Secretary, Fellowship of Medicine.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.

WEDNESDAY, March 6th.—4 P.M., Cases will be demonstrated by the Honorary Staff. Tea will be served at 3.45 P.M.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, March 5th and THURSDAY.—5 P.M., Dr. A. C. Roxburgh: Cutaneous Syphilis.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, March 4th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Adie: Progressive Muscular Atrophies.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Neurosyphilis.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Postures and Gaits.

FRIDAY.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Neurological Complications of Specific Fevers.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, March 4th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, March 5th.—3.15 P.M., Dr. C. C. Beatty: Hæmaturia.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, March 7th.—4 P.M., Dr. Nabarro: Points in Connexion with Tuberculosis.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

MONDAY, March 4th, WEDNESDAY, and FRIDAY.—5.30 P.M., Dr. A. Maitland Ramsay: The Eye in General Medicine.

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, March 4th.—5 P.M., Mr. P. Eggleton: The Chemistry of Muscle Contraction.

TUESDAY.—5.30 P.M., Prof. Karl Pearson: The Heredity of Albinism.

FRIDAY.—5.30 P.M., Dr. J. Howard-Jones: The Hygiene of the Mercantile Marine. (Third Lecture.)

NATIONAL COUNCIL FOR MENTAL HYGIENE, 78, Chandos House, Palmer-street, S.W.

WEDNESDAY, March 6th.—5 P.M. (at the Medical Society of London, Chandos-street, W.), Dr. Bernard Hart: The Minor Mental Disorders of Everyday Life.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, March 5th.—4.15 P.M., Dr. D. E. Core: Dreams.

FRIDAY.—4.15 P.M., Dr. F. E. Tylecote: Demonstration of Medical Cases.

ANCOATS HOSPITAL, POST-GRADUATE LECTURES, Mill-street, Manchester.

THURSDAY, March 7th.—4.15 P.M., Dr. Kletz: Diseases of the Gall-bladder.

UNIVERSITY OF MANCHESTER (Chemistry Theatre).

WEDNESDAY, March 6th.—5 P.M., Prof. A. V. Hill: Maintenance of Life and Irritability in Isolated Animal Tissues. (Ludwig Mond Lecture.)

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, March 8th.—3.30 P.M. (at the Royal Hospital) Mr. F. Wilson: Surgical Cases.

Appointments.

HOWELL, T. J., M.D. Edin., has been appointed Assistant Ophthalmic Surgeon to the Royal Victoria Hospital, Folkestone.

MAURICE-WILLIAMS, H. C., L.R.C.P. Lond., M.R.C.S., D.P.H., Deputy Medical Officer of Health, County Borough and Port, Southampton.

W., M.B., B.Chir. Camb., RICHARDS, W. G., M.R.C.S., L.R.C.P. Lond., and LEVY, A., M.R.C.S., L.R.C.P. Lond., Chief Assistants and Clinical Assistants.

Certifying Surgeons under the Factory and Workshop Acts: GRAHAM-YOOLL, R. W., M.B., Ch.B. Edin. (West Linton, Peebles); GREGORY, C. H., M.D., B.Chir. Camb. (Rugby); STEPHEN, W. S., M.B., Ch.B. Glasg. (Drummore, Wigtown); WATTHEWS, J. W., M.B., Ch.B. Edin. (Holmfirth, West Riding); WAKELEY, L. S. P., L.R.C.P. Lond., M.R.C.S. (Welwyn, Herts.).

Vacancies.

For further information refer to the advertisement columns.

Bedfordshire County Council.—Asst. M.O. £600. Also Asst. County Dentist. £450.

Birmingham, Ear and Throat Hospital.—2nd and 3rd. H.S. Each at rate of £150.

Birmingham, Queen's Hospital.—Anæsthetist, H.P.'s., H.S's., and Cas. H.S. Each at rate of £70.

Bootle Borough Hospital.—Jun. M.O. At rate of £125.

Brighton, Royal Sussex County Hospital.—Hon. Clin. Asst. to Ear, Nose and Throat Department.

Bristol General Hospital.—H.P.'s., H.S.'s., Res. Obstetric Officer. Also Cas. H.S. Each at rate of £80.

Bury Infirmary.—Third H.S. At rate of £150.

Calcutta, Presidency General Hospital.—Res. M.O. Rs.1.000.

Chester, East Lancs. Tuberculosis Colony, Barrowmore Hall, Great Barrow.—Asst. M.O. £250.

Chester Royal Infirmary.—H.P. At rate of £120.

Coventry and Warwickshire Hospital.—Res. H.P. £125.

Derby, Derbyshire County Sanatorium, near Chesterfield.—Res. Asst. M.O. £350.

Derby, Derbyshire Education Committee.—Asst. School M.O. £600.

Durham County Council Education Department.—Asst. Oculist. £600.

Durham County Council and Chester-le-Street Urban District Council.—District Tuberculosis M.O. and M.O.H. £700.

Essex, Administrative County of.—Asst. County M.O.H. £600.

Fulham Hospital, St. Dunstan's-road, Hammersmith, W.—Part Time M.O.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.

Hastings, Royal East Sussex Hospital.—Pathologist. £200. Also M.O. to V.D. Department, £375. Also Hon. Asst. Physician.

Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150. Also H.S. and H.P. At rate of £100.

Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.

Hostel of St. Luke, 14 ,Fitzroy-square, W.—Res. M.O. £200.

Jerusalem, St. John Ophthalmic Hospital.—Sub-Warden.

Kensington, Fulham, and Chelsea General Hospital.—Hon. Phys. for Diseases of Skin.

King's College, Hospital Denmark Hill, S.E.—Hon. Anæsthetist.

Leeds, St. James' Hospital.—H.P. and S. £200.

Liverpool County Borough.—Jun. Asst. School M.O. £600.

Leicester, Royal Infirmary.—H.S., Res. Cas. O. Also H.P. Each £125.

Lewisham Hospital, High-street, S.E.—Radiographer. £300.

London Temperance Hospital, Hampstead-road, N.W.—Hon. Anæsthetist.

Manchester, Ancoats Hospital.—Res. Surg. O. Also H.S. At rate of £100.

Manchester Ear Hospital.—Non. Res. H.S. Also H.S. At rate of £150 and £120 respectively.

Manchester, Royal Children's Hospital.—Two Asst. M.O.'s. Each at rate of £150. Also Res. M.O. and Res. Surg. O. Each at rate of £125.

Manchester, Salford Royal Hospital.—H.S. to Orthopædic Department. Also H.S. Each at rate of £125.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Res. M.O. At rate of £150.

Northampton General Hospital.—Two H.S.'s. Also Asst. H.S. Each at rate of £150.

Nottingham, Bagthorpe Institution and Infirmary.—Res. Asst. M.O. At rate of £300.

Nottingham, Broadgreen Sanatorium.—Asst. Res. M.O. £250.

Oldham Poor Law Institution, Rochdale-road.—Res. Asst. M.O. £200.

Oxford, Pembroke College.—Theodore Williams Medical Scholarship. £100.

Paddington Green Children's Hospital, W.—Hon Physician. Also H.P. and H.S. Each at rate of £150.

Richmond, Surrey Royal Hospital.—Sen. H.S. Also Jun. H.S. At rate of £150 and £100 respectively.

Royal Free Hospital, Gray's Inn-road, W.—Cas. Officer. £150. Also Res. Anæsthetist.

Royal London Ophthalmic Hospital, City-road, E.C.—Surgeon to Ear, Nose and Throat Department.

Royal Society of Medicine, 1, Wimpole-street, W.—William Gibson Research Scholarship. £292.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—H.S. At rate of £75.

St. Thomas's Hospital, S.E.—Asst. Surgeon in Orthopædic Dept.

Salford, Ladywell Sanatorium.—Asst. Res. M.O. £350.

Shanghai Municipal Council, Public Health Department.—Asst. Pathologist. Taels 650 per mensem.

Swansea Hospital.—H.S. £150.

Tunbridge Wells and Counties General Hospital.—H.S. £160.

Walsall, General Hospital.—Sen. H.S., H.S. Also Jun. H.S. At rate of £200, £125, and £100, respectively.

West London Hospital, Hammersmith-road, W.—Hon. Asst. Anæsthetists.

Willesden General Hospital, Harlesden-road, N.W.—Clin. Asst.

Wolverhampton, Royal Hospital.—Two Cas. O.'s and Anæsthetists. Each at rate of £125.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Hook Norton (Oxon.), Midsomer Norton (Somerset), Tadley and Baughurst (Hants), and Somercotes (Lincs).

Births, Marriages, and Deaths.

BIRTHS.

FORD.—On Feb. 22nd, at a nursing home, the wife of R. Kelson Ford, M.D., Fulwood Union Hospital, Preston, of a son.

JERWOOD.—On Feb. 18th, at Catmos, Wainwright-road, Altrincham, the wife of Bernard Jerwood, M.D., of a daughter.

LANGDALE-SMITH.—On Feb. 17th, the wife of Dr. H. G. Langdale-Smith, Stechford, Birmingham, of a dughter.

RICH.—On Feb. 15th, at Carlton House, Herne Hill, the wife of E. R. Rich, L.D.S. Eng., of a son.

ROLLER.—On Feb. 23rd, at a nursing home, to Caroline, wife of Roy E. Roller, M.C., of a daughter.

SHELDON.—On Feb. 22nd, at a nursing home, Southport, the wife of Harold Sheldon, M.D., 14, Albert-road, Southport, of a son.

WELLS.—On Feb. 15th, at Belvedere, Danbury, Chelmsford, the wife of Dr. J. Pascoe Wells, of a son.

MARRIAGES.

PLANT—HOLE.—On Feb. 13th, at St. Alban's Church, Streatham Park, S.W., Alfred Beresford Plant, M.R.C.S., L.R.C.P., to Marjorie Hole, elder daughter of Mr. and Mrs. R. Hole, of Sayers Common, Sussex.

DEATHS.

BATHE.—On Feb. 15th, at his sister's residence, "Bloomfield," Blackmore-road, Malvern, Allan Arthur Bathe, M.A., M.B. Oxf., in his 60th year.

BENSON.—On Feb. 21st, at St. Anne's-crescent, Lewes, George Vere Benson, M.A. Camb., Barrister-at-Law, M.R.C.S., L.R.C.P., late Coroner for East Sussex, aged 81.

BURRELL.—On Feb. 24th, Lionel Cottingham Burrell, M.A., M.B., M.R.C.S., L.R.C.P., of Arlarie House, Wansford, Peterborough, and late of Kew, Surrey.

KIDD.—On Feb. 21st, at Peak View, Rondebosch, Cape Town, Walter Aubrey Kidd, M.D., F.R.S.Ed., late of Blackheath, aged 76.

MOLONY.—On Feb. 20th, at Kerman, Persia, of enteric, E. F. Molony, M.R.C.S., L.R.C.P., Missionary, C.M.S.

PITT.—On Friday, Feb. 22nd, at Walton-on-Thames, of pneumonia, after five days' illness, George Newton Pitt, O.B.E., M.D., F.R.C.P., aged 75.

STEWART-SANDEMAN.—On Feb. 22nd, at Waverley-place, Aberdeen, of pneumonia, Laura Stewart-Sandeman, M.D., aged 67 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE BABIES' CLUB.

THE first annual general meeting of the Babies' Club was held at 29, Hyde Park Gate, lent by Lady Jones, on Feb. 26th. Mrs. William Piercy presided, and explained that the club, which is situated at 35, Danvers-street, Chelsea, came into being because a few mothers with young children, who had acted as helpers at infant welfare centres, desired to have the same sort of help and guidance in keeping their children well as was available for the poor. Mrs. Stanley Robinson said the founders of the club had realised that the trained medical assistance wanted by the mothers could not be obtained from their family doctors, who were too busy to give up the necessary time. It was decided to found a clinic where, on a single half-day in the week, an expert medical man would be able conveniently to deal with a number of healthy babies, and at the same time avoid encroaching on the domain of the family doctor. Any mother wishing to bring her child to the club had first to inform her family doctor of her intention and obtain his coöperation. The object of the club was the prevention of ill-health and cases of illness discovered by the medical officer were referred to the subscriber's family doctor. The first year's working showed a deficit of £458, but the membership had increased from 9 at the opening of the club in November, 1927, to 70 at the present date. It was hoped that the second year would see the club well on the way to being self-supporting. Each member paid five guineas a year, but a Samaritan Fund had been started to assist those who could not afford this sum.

Dr. H. K. Waller, medical officer of the club, said he found the same sort of minor ailments among the babies seen there as those found at an infant welfare centre in the East End; they were largely ailments due to faults of hygiene, ventilation, clothing, and the like. In some respects the poor mothers had gone ahead, and had remedied faults of management and feeding still found among the Chelsea babies by the time they reached the club. The East End mothers were experts; babies were their one great subject of discussion in their door-step parliaments, and they were quicker to note little points about their babies and to pick up hints offered than middle-class mothers. Dr. Waller had met with keen coöperation on the part of the nurses. English nurses were noted the world over for devotion to their charges, but there were a few rigid customs, in regard to such matters as clothing and ventilation, for example, which might be improved upon. The club was a centre for preventive medicine. It was not possible to prevent all illness, but it was hoped that, equipped with the armour of health, children would be better able to fight their inevitable illnesses.

Miss E. Raynham Smith, the matron, described her work as the first health visitor visiting in middle-class homes. By request she had started a class of instruction for expectant mothers, and applications for help in the most varied situations had been asked for and willingly given.

Sir Thomas Horder said this was a momentous and would indeed be an historical meeting if this first infant welfare centre for subscribing members proved to be a success. He was impressed by the fact that before starting the Babies' Club the committee had approached the Council of the British Medical Association in a spirit of courtesy. The B.M.A. must not be confused with the General Medical Council. It was an association of medical men existing largely to deal with questions in which the privileges and efficiency of general practitioners were concerned. The Babies' Club found that the Council of the B.M.A. was favourable, as far as any official organisation was able to be towards a new effort, and it gave the club its blessing. When, however, this blessing was presented for ratification to the Representative Body at the annual general meeting of the B.M.A. at Cardiff last summer, it was removed, though no ban was placed upon such clubs. Sir Thomas thought that he would sooner have the approval of the Council than of the Representative Body of the Association. In expressing his appreciation of the work done by the Babies' Club, he felt himself to be in good company, since the members had been addressed in their series of lectures by such leaders of the medical profession in matters of infant care as Dr. H. C. Cameron, Dr. David Forsyth, Dr. Allan Hamilton, Colonel R. McCarrison, Dr. Eric Pritchard, and Mr. George Waugh. This was an adventure, and a glorious adventure, and there were many other aspects of medicine, economics, and sociology which might have to be tackled on similar lines. Instinct did not carry people very far; education was essential. Sir Thomas Horder was impressed by the safeguards incorporated in the club's rules; against any infringements of the rights and privileges of general practitioners the family doctor was an essential part of the scheme. The results of the first year's working more than justified what the Committee had set out to do.

STANDARDISED YEAST.

YEAST is now recognised as a therapeutic agent, and its purity and activity should therefore be standardised. With this object the Standard Yeast Company, of Church-street, Chiswick, London, W., have laid down an elaborate plant for the production of pure yeast. The plant is a large one, capable of producing 15 tons in 24 hours; three chemists and five assistants control the process, and at each stage in the production the work is done under strict sanitary conditions. A single yeast-cell is picked out under the microscope, and placed in a Petri dish on agar-agar. The culture thus obtained is transferred to Erlenmeyer flasks containing sugar, thence again to tanks of increasing size containing sugar and phosphates. The largest tank has a capacity of 85,000 gallons. During the process the yeast is agitated by filtered air, the object being to separate the budding cells of the yeast from the parent, so as to quicken the growth. Subsequently the yeast is separated from the alcoholic wash (which, owing to the special process employed, contains only a negligible amount of alcohol), and is conducted through pipes to the pressing rooms. After passing through press filters it is ready to be made into tablets, which are sold under the name of Lyco Pure Yeast tablets. We understand that the beet-sugar used in feeding the yeast is carefully purified before use, and that during their formation and packing the tablets are not touched by the hands of the employees, every precaution being taken to avoid contamination. The whole of the plant is washed out once a week. An analysis of the tablets which has been supplied to us states that they consist entirely of pure pressed yeast, and weigh 0·305 g. each (about grs. 4½). Each tablet is stated to contain over 50,000,000 living yeast-cells and about the same number of dead cells. If yeast is to be given therapeutically it is certainly advantageous to use a pure culture, and the Standard Yeast Company's tablets appear to be satisfactory in this respect.

INFECTION OR INTINCTION.

To the Editor of THE LANCET.

SIR,—I shall be greatly obliged if those of your medical readers who are willing that their names shall be appended as signatories to the subjoined petition will signify the same to me as soon as possible by letter or postcard; also those who are willing to get petition forms signed. My profession awaits a lead from theirs.

"We, the undersigned registered medical practitioners, as Guardians of the Public Health, deem it our duty to petition all with whom the decision rests to discontinue the present method of administering the consecrated wine in the Holy Communion by means of a common cup as calculated to spread disease."

I am, Sir, yours faithfully,

S. CLAUDE TICKELL,
Vicar of Latton-cum-Evsey, Cricklade;
Hon. Secretary, Association for Avoidance of
Feb. 10th, 1929. Infection by Intinction.

A KING'S PHYSICIANS.

To the Editor of THE LANCET.

SIR,—Recent events have brought up in my mind a doggerel rhyme heard in childhood. Unfortunately I have it in a fragmentary condition and should be grateful if you could complete it and date it.

"Physicians attend His Majesty daily—
——, ——, Heberden, and Bailey;
All of them very excellent men—
——, ——, Bailey, and Heberden."

What two colleagues signed bulletins with Dr. Heberden and Dr. Bailey? And for what sovereign? The recollections of my grandmother, from whom I learned the verses, might go back to William IV., but I think the episode belongs to an earlier reign.—I am, Sir, your faithfully,

FRANCIS C. WALKER.
University of British Columbia, Jan. 28th, 1929.

THE COST OF SCIENTIFIC BOOKS.

IN the last number of his *Quarterly Review of Biology* (iii., 600) Prof. Raymond Pearl has an interesting analysis of the cost of biological books in 1928 based on the volumes sent to that journal for review. The average prices in cents per page, and the percentage difference from the 1926 figures, are:—

	Cents per page.	Difference from 1926
England	1·09	—15 per cent.
United States	1·14	+ 2 ,,
Germany	1·48	+36 ,,
France	0·45	+29 ,,
British Government	1·26	—
U.S. Government	0·21	—32 ,,

Such data are no doubt subject to many qualifications; but it is evident that French books are very cheap and German books are dear. The day of cheap blue-books full of useful scientific information seems also to have passed in this country.

An Address

ON THE

RÔLE OF STARVATION IN TREATMENT.

Delivered before the Medical Society of London on Jan. 28th, 1929,

BY EDMUND SPRIGGS, M.D., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO RUTHIN CASTLE.

IN the history of living organisms as a whole starvation, partial or complete, is a common experience. It is one of the chief dangers to be avoided by every sentient being. The human race has been occupied through the ages in acquiring a degree of command over the forces of nature in order to avoid this danger, and has developed a power of preparing, storing, and transporting food. This provision has been followed by a growing social sense that the destitute and the famine-stricken should be relieved, in respect of food at least, by more fortunate individuals or communities, and up till 15 years ago we should have said that natural starvation was becoming eliminated from human affairs. Since then we have witnessed and shared in the undernutrition of millions, and a new opportunity has been afforded of studying, with modern scientific knowledge and methods, the age-long phenomena of semi-starvation. In normal times, however, and in civilised communities there is probably more danger to health from over- than from under-nutrition, and there are many diseased states for which the withdrawal, for a time at least, of all or some of the food is beneficial.

Starvation may be defined as the lack of any or all of the elements needed for nutrition. It has been said that a strong man can do without oxygen for a few minutes, without water for a few days, and without food for a few weeks. We are here concerned with deprivation of food only, water being freely supplied.

The first symptom of starvation is hunger, which is associated with a sensation, which may be painful, in the epigastrium. It arises after the stomach has been empty some time, as the human race has always known, and as Beaumont[1] observed experimentally in Alexis St. Martin. The observations and cogent arguments of Cannon and Washburn[2] seem to establish that, as suggested by Weber in 1846, it is associated with strong contractions of the stomach which, like the sensations of hunger, are intermittent and pass off[3] after two or three days of complete fasting. Hunger is felt by people with no hydrochloric acid in the gastric juice. There is, however, a sense of need for food in starved people who complain of no pangs of hunger, for they tend to think and dream of food; but accompanying symptoms—such as lassitude, drowsiness, faintness, headache, and restlessness—are absent in many subjects, and vary with the individual. The pangs of hunger are not a manifestation of the general need of the cells of the body, because they cease long before the cells are starved, indeed when the blood, as we shall see, is carrying more food to them than usual; and they are relieved at once by putting food into the stomach, before assimilation can have proceeded far, or even by ingesting that which is not food. Appetite is in some degree independent of hunger, for we can desire and enjoy foods we like when we are not really hungry.

CLINICAL FEATURES OF EXPERIMENTAL FASTS.

In complete starvation the individual lives on his own tissues. Loss of weight is rapid at first, but soon reaches a regular rate varying with the store of fat, the fatter person losing more slowly, because each unit of fat gives ten times as much energy as the same weight of protein flesh. The body naturally conserves its energies, using fewer calories; the subconscious restriction of movement of a starving person is obvious to the onlooker. Rest lessens the expenditure, and the usual loss of weight in the later stages in subjects mainly resting is about one pound a day. The pulse becomes slower and the blood pressure falls. In Benedict's subject, who fasted 31 days, it was 132 mm. of mercury at the beginning and 116 at the end. In Cathcart's[4] subject it fell from 108 to 88 in a fortnight. Lower figures were observed by Rostoski[5] during a hunger strike of prisoners of war, the systolic pressure in one subject being recorded as 55 mm. The temperature remains almost constant in prolonged fasts, falling, for example, only 0·3° and 0·16° in two subjects, until the approach of death. No impairment of the mental state has been observed in experimental subjects. Some profess to be more able when fasting. In so far as they are relieved from the turgidity of a laboured digestion and the effects of alcohol and tobacco this is probably true, and tests in Benedict's case showed that the subject was at least as capable when fasting. Fasting men are not able to do more muscular work and their power of endurance is not increased. Healthy men and dogs have survived long fasts without any recognisable lasting evil effects. The power to fast and remain efficient differs greatly in different persons. Most of the experimental subjects complain of no symptoms. Cathcart's subject, a professional faster, aged 31, complained of headache and malaise on the fourth day, but this passed off. On the twelfth day he felt weak and giddy on quick movement. This was the subject whose blood pressure fell below 100. He remained in bed on the last two days of the fortnight's fast.

Fasting animals are more liable to contract an acute infection to which they are exposed and less able to resist the disease when contracted; experience teaches that the same applies to man. Warmth increases the resistance to inanition, but fever diminishes it. With partial feeding the period of resistance is much extended. A man can starve for a short period only, but he can survive being half-starved for a very long time.

In fasting the glandular organs of the body lose most weight, then the muscles, whilst the brain and heart are conserved at the expense of other organs. The following was the actual order of percentage loss of fat-free tissue of various parts of a dog after a fast of 24 days[6]: Pancreas (62 per cent.), spleen, kidney, liver (50 per cent.), genitals, blood, muscle (42 per cent.), stomach and intestine, lungs, skin, brain (22 per cent.), heart (16 per cent.), skeleton, eyes. The secretions quickly diminish, as shown by gastric juice and milk.

BIOCHEMISTRY OF FASTING.

The body as a whole does not starve; it lives on itself. When the mobilisation of its own stores to some essential part fails, then the end comes. This may be, and often is, long before the stores are exhausted, and when food is still being actively transferred to the various organs, as shown by the presence of fat in the body and its excess in the blood at death. The first call is made on the glycogen in the liver. As soon as this is gone, or nearly gone, more protein is used, especially if meat has been eaten recently. The so-called "deposit" or less essential protein is next burned. The body then has to draw on tissue protein and settles down to a minimum ration, getting as much as possible of its energy from fat and as little as possible from tissue. The rate of combustion of protein is followed by determining the nitrogen in the urine, and the amount of tissue protein used can be assessed by watching the excretion of potassium, magnesium, and sulphur. In prolonged fasting the excretion of nitrogen falls to 3 or 4 g. a day. If non-protein food is given it may be even less. Thus in a man with muscular dystrophy on a starch and cream diet I found in the urine on four successive days, 7·2, 3·6, 2·5, and 2·0 g. respectively.[7]

When weight is being lost steadily in partial starvation with a fair supply of protein there is, in some cases at least, a loss of protein tissue as well as

of fat. It is conceivable that this may easily arise by lessening of the glandular organs, even when the muscle tissue, through massage and exercise, was being kept up or even increased.

For example: An elderly man had been on a reduction diet for a month. His obesity, with circulatory embarrassment, had begun from overfeeding for fibroid phthisis which had now been quiescent for many years. The diet contained about 1060 calories (C., 65; P., 67; and F., 56). A test was made of the nitrogenous metabolism for six days by A. J. Leigh, B.Sc. During this period 4¼ lb. was lost, approximately ¾ lb. a day. Both the intake and the output were almost constant day by day.* The excess of the output of nitrogen in urine and fæces over the intake in the food was about 3 g. representing loss of protein tissue. The error of estimation of the nitrogen in food in a mixed diet is considerable, and the loss may have been rather less than that represented by these figures. The patient was feeling thoroughly well, improving in health, and taking more exercise daily.

The main source of energy in starvation is the stored fat, and those who have most bear fasting best and live the longest. About 90 per cent. of the needs are, on the average, supplied from fat. When it is nearly gone, more protein has to be used and there occurs an ante-mortem rise of nitrogen in the urine. The strain on the metabolism of fat leads to some acidosis, which can be shown by a fall of the carbon dioxide in the alveolar air as soon as the second day. Later oxybutyric acid, acetone, and ammonia occur in the urine, though not in the amounts found in severe diabetes. Acidosis was regarded as the cause of the headache and nausea noted by Folin and Denis[8] in fasting fat women; it was relieved at once by toast and tea. With repeated fasting the body becomes able to burn fat more completely without acidosis. A fasting man at moderate work burns more fat, but generally not more nitrogen.

After the glycogen in the liver is used there is little or no carbohydrate to be burned for energy purposes and, with combustion of fat and protein alone, the respiratory quotient falls to about 0·72 or lower. The blood-sugar, however, remains constant; it is needed and is formed from tissue protein, and probably from fat.[9] The essential carbohydrate metabolism is conserved to the end. Indeed, glycogen disappears entirely in an animal only after convulsions, and even then speedily reappears. Hypoglycæmia such as can be produced by insulin is not a natural phenomenon.

The energy needs of the body are, as above-mentioned, reduced as much as possible. For example, a man of 70 kilos (11 st.), who would burn material in a sedentary life to produce 2500 calories a day, will use 1800 calories in the first days of fasting and 1700 at the end of a week, an amount very near to his minimum requirement of 1600 calories. The blood tends to be a little more concentrated in non-protein nitrogen, including urea and uric acid and globulin,[10] and contains a good deal more fat, which is being carried to those parts which need it most. Its sugar content remains at a normal level. Anæmia is usually absent. It is hardly correct to speak of purification of the blood in fasting. The stream is rather in the condition of a highway along which such changes as there are are in the direction of mobilisation to meet a threatened danger. Depletion is of the glandular organs rather than of the blood. After a few days the urine of fasting men and animals commonly contains albumin. Bacteria continue to live in the intestinal secretions when all food is withheld at least a month. Lusk mentions that of 131 colonies taken from the stool of a subject who had fasted for 30 days, 110 yielded *Bacillus coli*, 17 *Micrococcus alveolus*, and 4 *Bacillus mesentericus*. He remarks that it does not appear to be possible to sterilise the intestinal tract or starve out bacteria from it.

Ancient Customs.

Fasting has been practised as a self-denying, ascetic, purifying, or religious exercise as far back as history goes. Among savage tribes the ability to fast was no doubt a large factor in eliminating the unfit. Fasting, perhaps on that account, was often regarded as a virtue; and there can be no doubt that the practice of total or partial periodical abstinence has been and may be of both physical and mental benefit. Although the so-called "hunger-artists" who have fasted under scientific observation in recent times have not manifested delirious or ecstatic phenomena, yet we find again and again in history that fasting has been used, as it is still, to induce a state of exaltation in which the subject sees visions and dreams dreams. Since prolonged and complete fasting is not associated as a rule with hunger, the feeling arises that the spirit is sublimated and independent of the body. He feels cleaner, freed of base desires, a better being in body and spirit; and a special authority has been ascribed to ideas, rhapsodies, or messages conceived, inspired, or delivered at such a time by medicine-men, fakirs, prophets, seers, and saints. Dr. Josiah Oldfield gives interesting examples from various races and periods.[11]

War-time Experiences.

During the war the supply of food to the Central Powers fell much below that necessary to nourish the people. Careful studies have been made, both in Austria and Germany,[12 13] and the scientific work of the previous generation as to the needs of the body was in all respects fully confirmed. In many parts of Germany, instead of a ration of 2400 calories and upwards, the food supplied extended only to 1300 to 2000 calories. The protein, vitamins, and mineral substances were generally in sufficient amount, the shortage being of carbohydrate and particularly of fat. It was found that in the early months sufferers from diabetes and gout improved in health and many of them ceased to need medical advice. Obesity was naturally also much benefited. The lack of food, however, led to severe under-nutrition, and it was said that there was hardly a poor person in Berlin who weighed more than 8 st. This wasting was accompanied by lowered efficiency and less resistance to disease. Nervous disorders began to arise; tuberculosis was rife and progressive, and anæmia became common. Patients with myxœdema did badly. The infectious diseases, such as influenza, appeared to be more severe, and it was particularly difficult to secure proper nutrition during convalescence, which was therefore prolonged and incomplete. Chronic diarrhœas and digestive diseases were adversely affected. This, no doubt, depended partly on the quality of the food, which was mainly vegetable, as well as on the deficiency in nutritive value. The medical opinion based upon the experience of a whole nation becoming largely vegetarian did not favour that régime as a permanent diet. The disease known as hunger œdema was perhaps partly due to taking so much salt to flavour the somewhat tasteless food and to abundance of water, but as it was most quickly relieved by giving fat, the lack of calories must be regarded as a main factor.

Starvation in Disease.

Complete fasting is beneficial in local diseases of the alimentary canal, such as appendicitis, local peritonitis, and ulceration; indeed, it is more reasonable for alimentary diseases than for any others since the organs of digestion are almost completely rested when the body fasts, whereas the remaining tissues have still their duties to perform. It is wise for this purpose, and indeed for all purposes, not to press the fast too far. The protein metabolism is not reduced to its low fasting value until about the fifth or sixth day, so that fasts for shorter periods do not put the same strain upon the resources of the body. Short complete fasts of one, two, or three days do good in a number of other diseases. On such days the patient will receive abundant fluid, and many medicine-men will allow tea, coffee, and fruit juice, and sometimes strained soup. In some cures a low diet of little milk, bread and butter, and salad is given for a day or two before the fast. After the fast it

* The figures are given in the appendix.

important also to begin the feeding gradually with small quantities of simple foods, such as meal soups, bread, and vegetables. Obesity, diabetes, and plethora are all benefited. Pneumonia and other severe fevers, acute nephritis, chronic uræmia, migraine, hyperthyroidism, and some skin diseases do well with this treatment in selected persons. Good results are also reported in local infections, phlebitis, leukæmia,[14] rheumatic diseases, rickets, and the vomiting of pregnancy; but I have not myself had experience of fasting in all these states. Caution must always be exercised and careful examinations made. Children and the cachectic and tuberculous should not be deprived of food for more than comparatively short periods. Much longer fasts have been employed, especially abroad, in many conditions. The opinion of scientific physicians in the countries concerned is not, however, favourable to them.

The use of starvation in the treatment of epilepsy is of much interest. Guelpa,[15] with Marie, applied his method of fasting and purging in epilepsy with benefit. Geyelin,[16] working with epileptic children, found good was done during the fast, especially when there was acidosis, but that the attacks recurred on resuming a normal diet. Wilder then suggested producing the acidosis without starvation by a diet sufficient in calories but deficient in carbohydrate, with minimal protein and abundance of fat—i.e., a ketogenic diet. Research has shown that it is the ketosis and not the acidosis, as such, which benefits the seizures, for acidosis produced in other ways is not effective. The results of two years' clinical trial were reported upon favourably by Peterman[17] in 1924; and Barborka[18] has recently reported benefit in 19 out of 32 adult patients.

Obesity.

The largest class of persons who benefit from undernutrition comprises those who have habitually taken food in excess of their need—namely, the obese. If obesity is not a disease it is at least an unhealthy state. It is associated with a lessened mobility, a lessened resistance to intercurrent disease, and a tendency to certain maladies, especially diabetes. Fat is due, like a bank balance, to a difference between income and expenditure. It is to be got rid of either by increasing expenditure, through exercise, the use of thyroid, and in rare cases by influencing metabolism with pituitary gland, or by diminishing income—i.e., the intake of food. A reduction of food, if made with due regard to physiological needs, will be successful without any other means, although it can be greatly assisted by the use of thyroid and suitable exercise; whilst the various methods of increasing expenditure will not be successful by themselves unless steps are taken to see that the intake of food is not increased proportionally—that is, unless the diet is controlled. The physical treatments to which patients attach importance, such as massage and baths, do not reduce weight; they are valuable as a means of keeping the muscles and the circulation in a good state during the treatment. Thyroid is a great help, but requires close control. When administered by the patient harm is often done. In all cases a thorough clinical and biological examination of the systems and secretions must be made before a reduction treatment is undertaken.

The obese may be divided roughly into two classes, large eaters and small eaters. The first class includes many able and active people who enjoy their food a little more than is good for them, but do thoroughly well with treatment. It includes also a very small subclass of unfortunate folk whose inability to resist the pleasures of food and drink make them unable to adhere to or profit by careful treatment. Those in the second class are careful as a rule about diet, but since youth have been the victims of their rotundity. These include the cases called endogenous. Only a small part of the food we eat is required for vital functions and movements; most of it goes to keep us warm. The rounder we get the less surface there is in proportion to weight, and the less fuel is required. Every little excess of food, then, goes to increase the roundness and diminish the needs, and so the vicious circle goes on. It follows that if the subnutrition treatment is continued long enough to take off a good deal of weight and alter the conformation of the body, the patient can look forward to eating rather more food later without increase of weight.

Method of Dieting.

The method of reduction which I use is that of giving an ordinary mixed diet, but in quantity lessened by measured steps, always bearing in mind that a certain proportion of protein, providing 6 to 9 g. of nitrogen, is needed daily. The basis of the diet is meat and vegetables, but if the amounts are measured there is hardly any food which may not be allowed—at least in small quantities. In sufferers from constipation meat is almost entirely excluded. It is essential to teach the patient that it is the total caloric value which counts, otherwise he runs away with the idea that some foods are fattening and that others, such as fruit, toast, and biscuits of protein or rye, are not, and that an obese person can be reduced by permitting this and forbidding that, irrespective of amount. The easier way to prescribe a diet is, of course, to give a list of foods to be taken or avoided, and this method is often followed by a measure of success. In many, probably in most, cases, however, if steady consistent results are to be secured, with permanent benefit to health, much work must be done day by day and week by week in measuring and varying the diet and making it conform as far as possible to the patient's own tastes. For if the particular foods given are not reasonably acceptable the diet will be a temporary measure only and will fail of the larger object—namely, to find a régime which he can manage and continue for himself. No fixed or published diet can, therefore, be the most suitable for any individual; his régime must be arrived at by collaboration between the doctor, the dietist, and himself, and it must be varied continually. With this important proviso, the following specimen diets are given as examples of some of the stages. In practice we avoid arithmetic as much as possible by using tables of food values looking rather like a book of logarithms, which have been constructed by my colleague, A. J. Leigh, B.Sc. In these the protein, carbohydrate, fat, and caloric values are worked out for each food, as served at table, in all the quantities likely to be required, in steps of 10 g. An adding machine is used to arrive at totals. The diets shown are roughly of 1300, 1100, 1000, and 600 calories. Different examples are given to show variety in the strictest diet. Almost any number of variants can, of course, be constructed. The figures representing analyses of foods as served are as near the truth as the nature of the work permits. The average error may be taken as ± 5 per cent., but this is small compared with the magnitude of the reductions and variations of the total amounts of food. Moreover, it tends to become less and less if the personnel in the kitchen, diet-rooms, and laboratory is unchanged. The foods are weighed as served on the Chatillon scales, on which the weight of the plate or small dish is automatically deducted by the simple device of a shifting dial.

The patient is allowed to drink water and other suitable fluids freely. The reason for restricting fluid at meals in cases of obesity is that drinking at meals leads to more food being taken. When all the food is measured this no longer applies.

In speaking of the results and of the pitfalls of partial starvation for obesity, it must be remembered that my own experience is almost entirely of cases which had failed to respond to simple measures adopted at home. The loss of weight is most rapid in the first days, and with it there quickly comes, as a rule, the feeling of returning lightness, vigour, and spirits. I formed the impression in earlier days that about the tenth to the fourteenth day a feeling of depression was likely to occur, often attributed by the patient to other causes, such as the weather.

Hunger is not a feature of this state, but a good meal, such as a large chop or whatever the patient prefers, in moderation, will clear it up. Of late years, however, since I have made a practice of warning the patient beforehand, I see this less often. An average loss of a stone a month is ample if permanent good is to be done. Very large flabby people will lose more and smaller harder people only 10 to 12 lb. The greates loss we have seen, excluding cases with dropsy, i 10 lb. in a week. In overweight with ascites an œdema one patient on a reduction and salt-free die lost 23 lb. in one week. Women lose on the averag rather less than men on the same treatment. This i probably because they tend to be shorter and rounde needing, therefore, less food per unit of body-weight

My experience is that it is usually better to giv four meals a day, tea being a very small meal, such a two biscuits with the tea. If hunger is complaine of—and it is surprising how seldom it is—a cup strained beef tea or of Bovril at 11 A.M. or bedtim will relieve without adding many calories. In th uncommon cases in which hunger is insistent it often better to make the breakfast a larger mea It may be repeated that, with the above-describe method, the body is never starving or half-starvin If enough, or nearly enough, nitrogenous food provided, with greens and some carbohydrate, th body supplies almost all its remaining needs from i own stored fat. One might think that acidosis wou develop from the burning of so much fat, but th supply of carbohydrate, which aids the combustio of fat, is generally enough to prevent that, and have not recognised it in any case.

It is unwise ever to attempt to reduce weig except on medical grounds, and it is not a doctor

I.—*Two Examples of Diets at the First Stage—About 1300 Calories.*

Sp. = special—i.e., sugarless (jam or marmalade).

Calories, 1340 ; C., 91 ; P., 86 ; F., 66.

Breakfast.	Grammes.	*Tea.*	Grammes.
Ham	35	Water biscuits	20
Egg	—	Butter	10
Toast	20	Milk	50
Butter	10	Sp. apricot jam	20
Milk	50		
Sp. marmalade	15	*Dinner.*	
Lunch.		Tomato soup	200
Roast beef	60	Fried plaice	50

		Butter	5

work. If a doctor allows a comfortable-looking woman of average height, and weighing 10 or 11 st., to persuade him to let her take a reduction diet because she would like to have a thinner figure, her face will become haggard. She will blame not her vanity but her doctor, and she will be right.

Persons who are really overweight improve in looks and in health steadily. Symptoms seldom arise during treatment, and those formerly present generally disappear. Especially striking is the loss of breathlessness; this is partly because there is less weight to be moved, but is mainly to be ascribed to lessening of fatty tissue among and within the muscle-fibres of the heart. If neuritic pains occur, and especially facial neuralgia or diarrhœa, or a total loss of appetite, amounting to dislike of food, the treatment should as a rule be altered. I have not seen serious weakness or anæmia as a result of treatment. The tendency is for earnest patients to eat less than is reasonable, and to urge the doctor to get quick results; he must in no circumstances yield to such pressure against the patient's interests.

The following case was of exceptional gravity, in both senses, but it responded typically to treatment and illustrates many of the above points.

A man of 30 (No. 1419) sought treatment for obesity, shortness of breath, and lack of energy. A consulting physician had found a quick pulse, with albumin, casts, and a suspicion of sugar in the urine, and had warned him that his state compelled anxiety. He had been fat since the age of 14, and at 20 weighed 16 st. Treatment at various times by diet, exercises, Bergonié chair, thyroid and pituitary extracts, had not arrested the steady increase of bulk.

On admission his weight was 25 st. 11 lb. in his clothes; height 5 ft. 8 in. He had been an energetic business man, travelling a good deal, but had felt lazy of late. Pulse-rate, 88. The physical examination of the heart could not be satisfactory, but nothing abnormal was heard; with X ray it appeared normal. The urine gave a faint trace of albumin. He was treated for a week by a moderate restriction of diet alone—namely, to 1000 calories—with a good deal of rest. On this 3 lb. was lost. The diet was then reduced to 800 calories, and a week later to 700; grs. 5 of thyroid were given twice a day, with massage, and the Bergonié chair was used. He began to lose 5 lb. a week steadily, and after four weeks was allowed to play three holes of golf, adding a hole a day. The treatment was continued with various modifications and alterations for eight and a half months, in which time 11 st. 11 lb. were lost, an average of 4½ lb. a week. This patient went through a sharp attack of bronchitis without causing any anxiety. Occasionally he would feel his heart beating, when the thyroid would be omitted for a time. In the latter part of the treatment he was subject to diarrhœa, and thyroid, greens, and fruit were all omitted.

It is now nine years since he left my care with instructions for the continuance of his régime, as required, under the supervision of his doctor. I have had a letter this month saying that he is well and energetic, and has regained 2 st. only of the 11½ he had lost.

The criterion of real success is that a patient shall not only benefit during his treatment but be able to keep well at home. Of this the above is a good example.

Another instructive case is that of a man weighing 21 st. 4½ lb., who felt his health was failing. He was treated at Ruthin Castle for nearly a month, losing weight steadily. He learnt the régime and then returned to his duties, intending to carry on the dietetic part of it for himself. This he did with success, and 11 months later weighed 12 st. 4½ lb.

It is not always easy to decide whether a case of obesity comes under the exogenous or the endogenous class, but in endogenous cases—i.e., those in which obesity has been present throughout life with no evidence of excessive consumption of food—the treatment and its effects are identical with those of cases classed as due to over-eating, except that the loss of weight may tend to be rather slower.

Single-food Cures.

Many special diets have been and are used for reduction, consisting of one food or of one kind of food; all that are successful necessarily bring about a form of undernutrition. One which has a reasonable basis is a measured milk diet, and in certain cases I employ this for a time, keeping the food value down from 1200 to 600 calories daily. Thus 4 oz. of milk every two hours for eight feeds a day give between six and seven hundred calories of a fairly balanced diet. We sometimes also give an orange day as a change during the régime, but not on a succession of days. Six large Jaffa oranges give 370 calories, mostly derived from over 70 g. of carbohydrate.

The cures I am now speaking of, however, are those in which a single food or single group of foods is continued for weeks at a time. Such single food diets are known as orange cures, grape and other fruit cures, potato and vegetable cures, oatmeal cures, &c. These cures are easy to organise. They are mostly forms of partial starvation, in some of which the necessary nitrogenous matter is not supplied, while in others there is vitamin deficiency. They all have one feature—namely, a time limit; the cure is for three weeks or four weeks, as the case may be. It is indeed essential that there should be a limit, for such unscientific experiments continued too long do serious harm. I have seen this on various occasions. The loss of weight is, for the time, satisfactory and sometimes phenomenal, but as the treatment can have no permanent basis the patient is liable to spend the rest of the year fattening for another cure.

I am convinced from long experience that the right way, laborious as it may be for the doctor and the dietist, is to construct a mixed diet of the required caloric value, altered as may be necessary from day to day, and to send the patient home with a practicable régime which he or she knows by heart, understanding also the principles on which it is founded. The patient must also be made familiar with the amount and form of physical exercise that is suited, not to a few weeks' cure, but to permanent healthy living.

Obesity is often complicated by other disorders and, as a general rule, if the state of the patient allows of treatment by partial starvation, the accompanying disease is benefited. Two conditions especially can nearly always be treated successfully in this way—namely, circulatory disorders and mild glycosuria.

Obesity and Diseases of the Circulation.

The good which can be done in a few weeks to the plethoric fat man, whose life is in danger from heart failure or cerebral hæmorrhage, is remarkable. Some of these cases call for immediate venepuncture and withdrawal of 300 c.cm. of blood, but that is a temporary emergency measure. It is inferior to reduction treatment because it does not deal with the cause—namely, the overloaded metabolism. If such individuals are treated under supervision for a month or two and put into a better way of living, efficiency is re-established, active life is much prolonged, and they are prevented from getting into the same state again. Two examples are given, both of whom did well under treatment. The first man returned to his former habits of life and died suddenly; the second took an opposite course and has kept well.

A man of 57 (No. 1573) complained of excessive weight, morning headaches, weakness, abdominal pain, and anal fistula. His height was 5 ft. 10 in., and his weight 18 st. 12 lb. His eyes were bloodshot, and he had varicose veins. His pulse was 50–60, and regular. He had mitral regurgitation, and the electrocardiogram showed an inverted T wave on lead III., suggesting myocardial change. He drank a bottle of champagne a day, and smoked 10–12 cigarettes and 4–5 cigars. With reduction diet, beginning at 1500 calories and falling to 700 calories a day, omission of tobacco and alcohol, massage, electric light baths, and cautiously increased exercise, all symptoms disappeared, and he became rejuvenated in a month. The inverted T wave had become normal. His circumstances were easy, and he was advised to give a longer time to treatment, but felt it his duty to return to his firm. Some months later his doctor let me know that he had returned to his old manner of life, though never a drunkard, and was increasing in weight. He stated his intention of giving himself two or three months' treatment and holiday in a short time. A few weeks later he did his day's work in town, motored to the south coast to dine, motored back late at night, and was found dead in bed the next morning. In this case excess of tobacco and alcohol played a part, as well as over-eating and want of exercise.

The second example is that of a man of 60 (No. 2197) who sought admission for breathlessness, giddiness, and headaches. Six months earlier the giddiness had been more than usual after exercise, and some paresis of the right side of the face and tongue had come on and remained. He was florid, 5 ft. 7 in. in height, and 11 st. 12½ lb. in weight. There was flattening of the right side of the face, but no loss of power in the limbs. He had some congestion at the bases of the lungs, and his radial artery was thick. His blood pressure was 240/160, his hæmoglobin 104 per cent., and he had 5,400,000 red cells. Central vision was gone in the left eye, and there was recent hæmorrhage in the fundus. The patient took a little alcohol and one mild cigar a day. His urine had a trace of albumin, and a few granular casts. Kidney efficiency tests gave normal figures.

On a diet of 1000 calories, reduced gradually to 800 calories, and appropriate physical treatment, this patient lost a stone in a month and the blood pressure fell to 185 mm. He was given a régime and advised to live carefully and give up shooting, and he followed the advice. It is now five and a half years since his first admission. His progress has been checked at intervals since, and has been consistent. During the last three years he has taken up quiet shooting again with enjoyment and benefit. The blood pressure tends to remain at about 200 mm., but there has been no further hæmorrhage.

Cases with high blood pressure benefit almost invariably by reduction if they are overweight, and in the majority the blood pressure is reduced also.

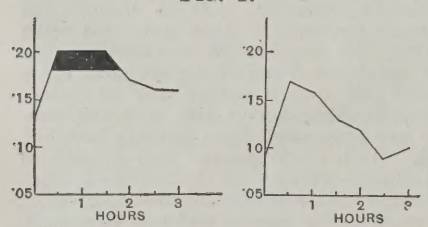
For example, a lady (No. 2316), aged 51, short, weighing 11 st. 11 lb., who had had several alarming hyperpietic attacks with unconsciousness, was admitted with a systolic blood pressure of 240 mm. With gradual and continuous reduction 2 st. 2 lb. was lost, and the blood pressure, which was obstinate at first, began to come down. That is now five and a half years ago. The systolic blood pressure was recently 176, the attacks have ceased, and she is a normal energetic woman.

The reduction of blood pressure, although it occurs in experimental fasting, cannot be ascribed in these patients wholly to the reduction of food value, since hyperpietic patients who are not overweight and are not reduced often yield to a quiet régime with regulated rest and exercise and control of the quality of the diet.

Obesity, Glycosuria, and Diabetes.

It is well known that obesity predisposes to diabetes. R. S. Allison[19] reviewed 121 of our cases of obesity two years ago, and found a not infrequent decrease of carbohydrate tolerance; this appeared to be in the main, though with exceptions, dependent on the length of time that the obesity had existed unchecked. The diabetic tendency would remain undiscovered in many cases if a sugar-tolerance test were not performed.

Fig. 1.



17 st. 2 lb. 13 st. 3 lb.

Showing improvement in sugar tolerance with reduction of weight.

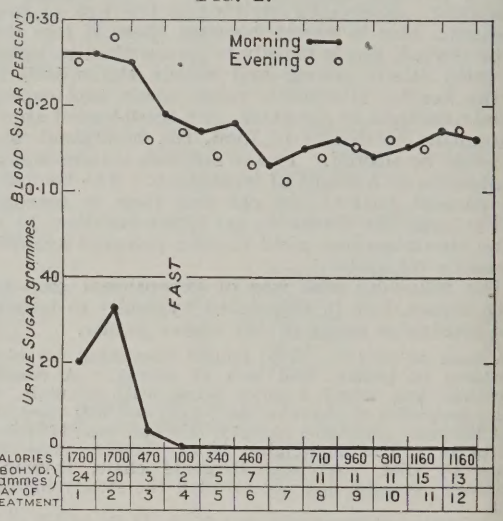
Further, an improvement in tolerance or even a return to normal may take place if weight is reduced. Curves illustrating these points are shown in the paper referred to, and two of them are here reproduced (Fig. 1).

Many mild cases of diabetes in plump people need no other treatment whatever than a reduction in the amount that is eaten. Patients naturally prefer this to a diet which is different in quality to that of others.

A man of 57 (No. 3680) called in his doctor on account of pains in the left shoulder and arm. The heart sounds were poor, and the blood pressure 200/90. The urine was found to contain albumin, 6 per cent. of sugar, and diacetic acid. On inquiry, he admitted thirst and polyuria. Sugar had been found five years before but disappeared, and he had been passed for life assurance two years before. He weighed 12½ st., was short, stout, plethoric, and nervous. He had a hæmoglobin percentage of 105, and 6,200,000 red cells in his blood. He had been taking ordinary food without sugar. The blood-sugar curve was typically diabetic, rising from 0·21 to 0·30 within an hour and falling to 0·21 again in three hours. Many teeth showed periodontitis. The affected teeth were removed, and the patient was given ordinary food, minced at first, to the value of 1500 calories a day, reduced gradually within 14 days to 600 calories.

He was better from the beginning; in about a fortnight the sugar was absent from the urine, and in normal quantity

Fig. 2.



in the blood. After a month he felt and looked well, having lost 10 lb. in weight. He continued on a similar diet at home but not weighing his food, and five months later returned for a check of his state; he was then a stone and a half lighter than when first admitted, with a normal circulation and blood-sugar, and no sugar or albumin in the urine. His self-controlled diet contained about 1100 calories. After a year he contracted pneumonia on a holiday and recovered. The blood pressure and weight then rose again, but with continued observation by his doctor and a six-monthly checking at Ruthin the plethora, diabetes, and nervous state were all greatly improved again, and he has kept on a good plane of health.

In this patient the diabetic state was not only kept under control, but is better fundamentally, as shown by the sugar-tolerance curve taken a year later. The curve now began from a normal level; it still rose too high, but returned nearly to normal in three hours, a very different picture from that of a year before. The red corpuscle count was 5,200,000—i.e., a million less than on admission.

Another case, female, aged 65 (No. 2933), of diabetes with a tendency to obesity, complicated by achylia and a duodenal pouch, has now been under observation at intervals for three and a half years. This lady has had insulin for several periods with a diet of 1800–2000 calories. She always does well, however, the urine becoming sugar-free on an ordinary diet restricted to 1100–1500 calories, without insulin.

Diabetes without Obesity.

The fasting treatment of established diabetes, foreshadowed by Naunyn and von Noorden, and vigorously applied by Guelpa, was put on a scientific basis by F. M. Allen as the results of numerous and painstaking researches upon animals and patients. The introduction of this method, which has been used for about 15 years, marked a great advance. With total or almost total abstinence from food, but with abundant warm fluid, the urine becomes free from sugar, the blood-sugar falls to normal, and acidosis is diminished. We usually give coffee or tea for breakfast and tea with a tablespoonful of skim milk, and at midday and 7 o'clock a bowl of strained soup. It may be noted that tea and coffee are among the substances which inhibit the strong contractions of the fundus of the stomach associated with hunger. A fast of one, two, or more days is well borne as a rule, the patient feeling better and clearer for it. The pancreatic rest has more than a temporary effect in most cases, for when food is added in gradually increasing quantities after the fast it is found that the

power of assimilation has improved.[20] For severe cases the method, though the best we had, was not permanently efficacious, and the discovery of insulin by Banting and Macleod has made the successful treatment of such patients a daily beneficent marvel. There is, however, a large number of mild cases of diabetes in which the dietetic control is best begun by a short complete fast. Time is saved, the sugar is abolished in the urine, and the blood-sugar brought quickly under control. The diet is then gradually raised in the usual way, and often insulin can be avoided. Even though insulin may prove to be needed later, it is wise not to give it in a case of mild diabetes until a fast and graduated diet have been followed by recurrence of sugar in the urine or of high values of the blood-sugar. Fig. 2 is the curve from a case, showing the effect on the sugar in the blood and urine during the fast, which was almost complete. The food value and the amount of carbohydrate given each day are shown below the curve.

Dangers of Severe Hunger Cures.

The fact that starvation, complete or partial, does good to a great many overfed or diseased people has led inevitably to its abuse both within and without our profession. At the end of the first week, hunger having passed in 48 hours, the subject of a complete fast may develop psychic exaltation. He then enters into the happy certainty of the insane, but is manifestly not in a state to interpret physical needs and decide when and what food should be taken. Therein lies a special risk to health. A cult of nature or fasting cures has sprung up again in our day, especially abroad, in which the benefits which some derive has led to the application of the same method to others who do not need or are not fit for it. The fact that a healthy man can fast three weeks or more, feel better, and ultimately be no worse is proof of his endurance and of the wonderful power of the human body to surmount adverse conditions; it is not proof that fasting to such an extent is beneficial to him. The upholders and the subjects of these cures are apt to go beyond and outside what is known to be true in defence of the treatment. A good summary of the point of view is given in a paper by Lochte,[21] of Göttingen.

He relates that a doctor who gave fasting treatment in his own sanatorium was consulted by a man of 52, weighing 10 st. 2½ lb., who complained of headache and of being easily tired. He wished to try the cure, and to put himself into a hygienic way of life before emigrating. On physical examination he appeared to be sound. The régime consisted essentially of living upon lemon squash with a teaspoonful daily of a vitamin preparation. This was followed for six weeks and two days, when the weight had fallen to 7 st. 2 lb. Muscular twitchings then appeared, followed by disorientation, coma, and, in spite of the supply of food, by death eight days later. A legal inquiry was held, and the doctor was arraigned for causing the patient's death through negligence. He made a long defence, which I quote in summary.

The defendant said: Modern medicine was false, especially Voit's teaching. Food does not make folk strong and healthy, and they are not sick and weak without it. This is shown by the fact that there is tiredness and desire for stimulants after a large meal. The modern bowel is unclean. Fasting is concentrated nature-healing. Anyone who fasts a fortnight gains strength every day, and many nervous diseases, also asthma, catarrhs, headaches, and heart, alimentary and skin diseases are not otherwise cured. Phthisis heals rapidly within four weeks. A fasting man sees for the first time, uninfluenced by desires, the world and his fate, and his spiritual life receives new growth. A fast should last three weeks on the average, often longer, and should be followed by a building up on vegetable foods. It should not stop until ketones are absent and hunger returns. Many men have fasted 40 days, following their occupations, and feeling fresher and more able all the time. Acute diseases seldom attack the fasting. "Crises" may occur with bad taste, pains in the back, yawning, weakness, shivering, and vomiting bile. When such symptoms arise, the right course is not to interrupt, but to continue, the fast. Deaths are sometimes unavoidable, but were not more frequent than after surgical operations. He hoped to diminish their number by the study of causes and treatment.

The defendant also stated that he did not order the cure but, finding no contra-indication, gave it at the request of the patient, who was not ill. No biological tests were made, though he had mentioned such. He attributed death to hot baths, which the patient took daily against his advice. The post-mortem has not allayed his suspicion of an undiscoverable vegetable poison.

Other doctors conducting similar cures gave evidence that in a private sanatorium the doctor could not be expected to make tests and metabolism observations, and could not prevent a patient from exceeding the régime.

The prosecution pointed out that many of the statements made were not scientific facts, and that the authorities quoted were not authorities. The defendant's statement as to the absence of contra-indications was weakened by his other statement that he treated all sick people with fasting cures. The initiation of such a fast was a serious affair. No tests and no records of diet were made; indeed there was no means for making metabolism investigations. The clinical thermometer was not used till the day of death. No medical notice was taken of the signs of acidosis and narcosis or remedies used. The doctor was found guilty of negligence in submitting a healthy or nearly healthy man to a dangerous treatment, and not taking the necessary care in the conduct of the cure. He was fined 300 gold marks, or a month's imprisonment, and costs. Naturally, no opinion was given by the court on the value of the method of treatment, but it was stated that such fast cures, if used at all, ought to be conducted in a clinic with efficient daily control of the metabolism.

Lochte concludes that the value of cures of the severity advocated is in the highest degree dubious on account of their effects on both mind and body.

Appendix.

Results of Investigation of Nitrogen Metabolism on Reduction Diet. Analyses by A. J. Leigh, B.Sc.

Period six days. All food was weighed and the nitrogen in the food calculated except for soup, which was determined on four days. Nitrogen in urine was determined daily in duplicate. Fæces were marked off with charcoal and collected over whole period, the average nitrogen content being determined in duplicate.

Date in Jan., 1929.	Diet. Excluding soup. Cals.	C.	P.	F.	Nitrogen (N.). Soup.	Rest of diet.	Total.	Urine N.	Excess N. passed in urine.	Vol. urine.

Weight 8 A.M. Jan. 4th, 14 st. 6¼ lb.
,, 8 A.M. ,, 10th, 14 st. 2 lb.
Loss of weight, 4¼ lb. = ¾ lb. per day approx.

Conclusion.—The patient had not reached nitrogenous equilibrium in six days, the excess output in urine and fæces on the sixth day being approx. 2 g. nitrogen, and the average for the period approx. 3 g. nitrogen.

Notes.—The nitrogen figures in the diet are probably correct to the nearest whole number only.

THE BACTERIOLOGY OF A SERIES OF UTERI REMOVED AT OPERATION.

By ELIZABETH H. LEPPER, M.B. Lond.,
PATHOLOGIST TO THE ELIZABETH GARRETT ANDERSON HOSPITAL, LONDON;
AND
MARJORIE MARTLAND, M.B. Lond.,
BIOCHEMIST TO THE HOSPITAL.

A STUDY of the bacterial flora of the interior of the uterus, with special attention to anaerobic organisms, was undertaken with two objects. The first was to ascertain its bearing on puerperal infection. The occurrence of *Bacillus welchii* in puerperal sepsis has been known for the last 30 years, and the work of Lehmann [1] suggests that anaerobic infections are far more common than was previously supposed. In his series of 1664 cases of infection after abortion, 19 per cent. were proved to be caused by the Welch bacillus. Its entry into the uterus is not always easily explained, as there are many cases in the literature where there is no reason to assume that the organism has been introduced by interference per vaginam. It is claimed (Lea and Sidebotham) [2] that various organisms, including hæmolytic streptococci, may exist harmlessly in the puerperal uterus, giving rise to no signs or symptoms. If this is so it is conceivable that an anaerobe such as *B. welchii* might inhabit the non-pregnant and apparently non-infected uterus, leading a quiescent existence unless aroused to activity by some change favourable to its growth in the local condition. The second consideration which led us to seek for anaerobic organisms in utero was the possible relationship of the Welch bacillus to the "red degeneration" of fibroids. The red, œdematous appearance of these tumours is similar to that of muscle infected with the bacteria of gas gangrene; it also calls to mind the change seen in the muscle of the meat-media in which anaerobes are grown in the laboratory. Clinically, such an association has been noted. In a case published by Gabriel and Kingsbury [3] *B. welchii* was demonstrated in a gangrenous fibroid, and also in a second fibroid which they describe as soft, pinkish, and having the histological appearances of red degeneration. We therefore made a routine bacteriological examination of the uterine endometrium and musculature, and especially of uterine fibroids, to discover whether anaerobic organisms could be found therein and, if so, whether their presence was of common occurrence.

Method.

In view of the difficulty of avoiding contamination per vaginam no cultures were taken by way of the cervical canal. Thanks to the coöperation of the honorary surgical staff of the Elizabeth Garrett Anderson Hospital, without whose help the investigation could not have been attempted, we were enabled to take cultures from 47 uteri within a few minutes of removal from the body. No selection of cases was made. The specimens were removed by abdominal hysterectomy performed for fibromyoma or for fibrosis uteri, with three cases of adenomyoma and two of carcinoma fundi. One case of fibroma of the ovary was included. In no case was the operation undertaken for any septic condition.

The material for culture was taken by means of sharp metal cork-borers, previously sterilised and kept ready for use. These were pushed through the uterine wall from the peritoneal surface, previously seared, into the lumen, and the portions of muscle and mucous membrane withdrawn in the borers were transferred to culture tubes with the help of a sterile trocar. Next, a small amount of sterile broth was injected into the uterine cavity by a pipette inserted through the track of the borer, and was withdrawn at once for culture. Finally a boring was made into the centre of any tumour that might be present, the softest being selected in cases of multiple fibroids. Cultures were made into a meat-medium, as we found that any organism grown from the uterus was facultatively anaerobic in so far as it gave good growth in this medium. Aerobic and anaerobic subcultures were subsequently made, and the various organisms isolated. Microscopic sections of uteri and fibroids were examined for organisms and the histological appearances noted.

Results.

Analysis of 47 cases examined shows that 41 cultures made from the endometrium and wall of the fundus uteri gave 17 positive results, and 37 cultures from the interior of uterine tumours gave 13 positive results. The nature, number, and location of the organisms found is shown in the following table:—

Nature of organism.	Isolated from fundus uteri.	Isolated from tumour.
Streptococcus	8	3
B. welchii	1	2
Gram-negative bacillus ..	2	2
Diphtheroid bacillus	3	3
Ditto, with staphylococcus ..	1	3
Staphylococcus..	2	0

Macroscopic examination.—Hyaline degeneration was seen in all our infected tumours, and was marked in those from which *B. welchii* was grown, but other fibroids in which organisms were not found showed this change in no lesser degree. No discoloration was present in the anaerobically infected tumours. Only one "red" fibroid occurred in our series; this grew a non-hæmolytic streptococcus.

Microscopic examination of the tissues from which cultures were taken gave evidence of definite inflammatory reaction in 21 out of the 30 positive cases. These include all those from which streptococci or *B. welchii* were grown. The histological appearance of the tissues from which the Welch bacillus was isolated were similar in our three cases. In one the bacillus was grown from an adenomyoma, the same organism being found in cultures of the endometrium; in another from a fibromyoma. All showed hyaline degeneration of the muscle-fibres, while the connective tissue was œdematous and in places appeared transparent. These almost structureless areas contained some polymorphonuclear leucocytes and plasma cells and many basophilic cells. The basophilia was a striking feature, the cells being apparently nearly twice as numerous as in cases infected with other organisms. It is possible that the transparency of the connective tissue might account for this appearance by bringing into view a greater depth of the section than is usually visible. In the fibromyoma large numbers of Gram-positive bacilli were seen; these were present in the transparent areas in certain parts of the fibroid, but were sought in vain in other parts of the same tumour. This patchy distribution stresses the importance of taking several good-sized pieces of tissue for culture, and shows how it would even then be easy to miss the infecting bacillus in culture as well as in section.

The œdematous connective tissue swarming with bacilli and showing only slight inflammatory reaction gave a picture very like that seen in sections of muscle of a guinea-pig killed by injections of *B. welchii*. We are greatly indebted to Dr. Muriel Robertson for the use of this material for comparison. The histo-

logical appearances of such infected muscle has been described in detail (McNee and Shaw Dunn,[4] Kettle [5]).

Of the Gram-negative bacilli found three times in culture, two were hæmolytic and resembled an influenza bacillus, forming on boiled-blood-agar small transparent colonies which died unless sub-cultured frequently. They did not, however, give the fermentative reactions of the "hæmolytic influenza bacillus." The third was a coliform bacillus of the *anaerogenes* type.

Of the 12 specimens growing staphylococci and diphtheroid bacilli, alone or together, five showed slight round-celled infiltration in section, the remainder giving no evidence of inflammatory reaction. In view of the possibility of contamination with these two organisms it is doubtful whether they should be regarded as having any pathological significance.

Conversely, where sterile cultures were obtained the microscopic appearance of the tissues was in very fair agreement, 27 of these specimens giving no evidence of inflammatory reaction in section, while 11 others showed varying degrees of inflammatory change. Of these, two were cases of carcinoma of the fundus showing marked polymorphonuclear infiltration with necrosis of the growth, while five were sections of uterine wall showing only slight round-celled infiltration such as would not be incompatible with the normal changes of the menstrual cycle.

In brief, the conformity between cultural and histological findings seemed sufficiently close to warrant the belief that when we grew an organism and found evidence of inflammatory change in the tissue from which the culture was made, we were indeed dealing with an infected uterus or tumour. On such an assessment we found organisms which we believe to be pathogenic in 27 per cent. of the uteri and in 19 per cent. of the fibroids examined.

Discussion of Results.

We have found that organisms are present in the interior of the uterus more frequently than is commonly supposed. Moreover, various organisms, including *B. welchii*, may occur in fibromyomata and in adenomyomata in cases where their presence is unsuspected. It is impossible to diagnose the nature or even the presence of infecting organisms from the naked-eye appearance of such tumours; a fibroid containing anaerobic bacilli showed no features by which it could be distinguished from many others in which no evidence of infection could be discovered. A red coloration of a fibroid is not necessarily associated with the Welch bacillus, a streptococcus having been isolated from the only case in our series. It is interesting to note in this connexion that the production of a pink colour of muscle in meat-medium, which we had supposed to be a specific property of anaerobic bacilli, was given by other organisms grown in the same medium, notably by streptococci. Apparently any organism which grows well in the meat-medium without causing much change in the reaction will produce the conditions necessary for the reduction of the cytochrome of muscle which is responsible for the pink colour. Microscopic examination of the tissues may show changes suggestive of anaerobic infection, and the bacilli may be demonstrated, but they are difficult to detect owing to their tendency to localise in small scattered areas.

These latent infections are therefore impossible to diagnose at operation, and recognition by the pathologist may come too late to be of service to the surgeon, since it is impracticable to make cultures and microscopic sections of every fibroid removed. It is therefore well to remember that signs of toxæmia, with or without fever, following removal of uterine tumours may be caused by the Welch bacillus. The clinical picture in such cases, described by Nürnberger [6] and by Lehmann (loc. cit.), is sufficiently characteristic to justify treatment with antiserum even if the bacillus has not actually been found. It seems probable that gentle handling of these tumours during removal, with avoidance of bruising or injury of tissues, may be of the utmost importance in preventing generalisation of infections.

THE THERAPEUTIC APPLICATION OF ACETYLCHOLINE.

By MAURICE VILLARET,
PROFESSEUR À LA FACULTÉ DE MÉDECINE DE PARIS; MÉDECIN DE L'HÔTEL-DIEU;
AND
L. JUSTIN-BESANÇON,
CHEF DE LABORATOIRE À LA FACULTÉ DE MÉDECINE DE PARIS.

In this paper we propose to summarise as briefly as possible the present position of our research on acetylcholine, believing that it may be of interest to our English colleagues.
